THE

PORTABLE ENCYCLOPÆDIA

OR,

A DICTIONARY

OF

THE ARTS AND SCIENCES,

ON THE BASIS OF DR. GREGORY'S.

COMPREHENDING THE LATEST IMPROVEMENTS IN EVERY BRANCH
OF USEFUL KNOWLEDGE.

Illustrated by Numerous Engravings.

BY JAMES MITCHELL,

MARKET HARBOROUGH.

LONDON:
PRINTED FOR THOMAS TEGG, 73, CHEAPSIDE;
R. GRIFFIN AND CO., GLASGOW;
TEGG AND CO., DUBLIN:
ALSO, J. AND S. A. TEGG, SYDNEY AND HOBART TOWN.

1839.

PRINTED BY J. HADDON, CASTLE STREET, FINSBURY

PREFACE.

In presenting to the public a work like the present, it is naturally to be expected that the Editor should give some account of the grounds on which he rests his claim to attention; and with this expectation he readily complies. The number of Dictionaries professing to comprehend a general view of the Arts and Sciences, in a condensed form, already extant, is very great; yet, great as it is, it is every year rapidly increasing. The reason of this it is scarcely necessary to specify, since it must be obvious to every one; for who does not know, who does not feel, that the demand for information among all ranks in society has become unparalleled in the history of the world.

To satiate this universal desire for knowledge, the press, free and powerful as it is, is found to be scarcely adequate. Under such circumstances, it is not at all surprising that, amongst the numerous productions with which it teems, much imperfection should be found. Indeed, to expect things to be otherwise, would be to expect that the powers of the human mind should attain to perfection without passing through those *degrees* of developement with which the great Author of nature, and of all order, has inseparably connected so much of our intellectual enjoyment.

Improvement is the very soul of all human effort: remove the hope of this, and you change the gay face of nature, into the cheerless gloom of annihilation. Nay, even viewing man as a being destined for immortality, what were his brightest prospects without the assurance of eternal progression in all that is suited to administer to his delight?

It is on this broad principle that the Editor of the following sheets would wish to advert to the generality of the several works, of a similar nature to his own, already before the public; and while he adopts as his own motto the well-known words—

> "Quod potui perfeci,"

he is well aware that common candour requires that he should admit its applicability to the productions of his fellow-labourers in the field of science. It does not, however, follow from this, that he must shut his eyes against the glaring imperfections of some of them. Comparisons are often invidious, and therefore he forbears to make them; but he thinks it a duty which he owes to the public, to caution them against being imposed on by the specious pretensions of a small book which aims at nothing short of being considered as a scientific companion to Johnson's Dictionary of the English Language! To point out the numerous errors and deficiencies of this volume, which makes such lofty pretensions, would require several pages: it may be sufficient to say, that the language is often highly ungrammatical; the orthography prodigiously incorrect; the printing slovenly; references are often made to articles on which there is not one word said; plates are given without letters of reference to the letter-press; and references are made in the letter-press to plates that do not exist; the plates themselves, with a few exceptions, are coarse woodcuts, in some of which the engraver has shewn his scientific knowledge

by carefully imitating the imperfections of the *worn-out* plates from which he copied. To the above may be added, that the arrangement is often incorrect; and, although the work professes to be a new, a corrected, an enlarged, and improved edition of one known by the name of Watkins's Portable Cyclopædia, it does not contain one column of original writing—no not one solitary paragraph; and the reader will look in vain for one word of information on most of those subjects which mark the rapid progress of science in this country, and in other parts of the world.

These are certainly matters of great importance in a work which professes to put the student in possession of a condensed view of the latest improvements in every progressive science; and which, from its richness of information, the excellence of its execution, and the lowness of its price, has (says the editor,) no parallel in any modern language!

Nor can the editor of the present volume dismiss this subject without adverting to another circumstance, which, although not of essential importance, he has already found operating to his disadvantage, he means the identity of names. It is very true that if the titles appended to a man's name were always certain indications of merit, there might be some honour, even in being mistaken for an L L. D. and an F. A.S.; but the potency of mere titles is now happily expiring:—the *public, as such,* begin to judge of men's powers from their performances; it is on this ground that the Editor of the Portable Encyclopædia takes his stand; and the only thing he solicits from those into whose hands his work may fall, is a close and candid perusal of it.

He lays no claim to perfection: some few typographical errors he perceives have found admission into his pages, but they are of the most unimportant description; and he must say they have occurred in despite of the closest vigilance, most of the proofs having undergone three readings, and some of them four. It has been his constant endeavour to exclude all obsolete and extraneous matter, and at the same time to render the work as comprehensive as possible. Several of the leading articles have been entirely re-written; most of them have been much altered and improved; much original matter has been added; and the whole has been brought down to the latest date. The improvement, however, which the whole has undergone, will be best understood by inspection, which renders a detail of it in this place the less necessary. As to the engravings, it is hoped that both in the choice of the subjects, and in the execution of the workmanship, they will afford the utmost satisfaction; indeed the general appearance of the volume will show that the publisher has spared no expense to render it worthy of public patronage. The Portable Encyclopædia, as the title-page announces, is formed on the basis of Dr. Gregory's "Complete Dictionary of the Arts and Sciences," a work too well known to require any encomium here, and which has only become imperfect in consequence of the vast acquisitions which the arts and sciences have made since it was published. The deficiencies of Dr. Gregory's excellent work the editor has endeavoured to supply from the most modern and best established authorities, to whom he takes this opportunity of expressing his obligation, and of offering his sincere thanks.

In conclusion, the Editor would observe that, while he trusts his work will be found peculiarly serviceable to youth in general, and to the members of Mechanic's Institutions, and to the frequenters of Scientific Lectures in particular, he hopes it will also be of service, as a book of easy and immediate reference, to gentlemen whose time is of too great value to admit of their perusing numerous pages in quest of a general idea.

THE PORTABLE ENCYCLOPÆDIA.

A.

A. This letter is placed first in the alphabet of every language with which we are acquainted, with the exception of the Ethiopic, in which it is the thirteenth. The reason of this is by some supposed to be the great simplicity of its sound. In the Continental, and in the Oriental languages, this letter maintains a greater uniformity than in the English language, in which it has three distinctly different sounds, besides a variety of occasional sounds. The three principal sounds are denominated, the broad, the open, and the slender, as heard in the words, wall, father, face. In grammar, it is styled the indefinite article, and denotes one, as a man. In music, A is the nominal of the sixth note in the gamut: also the name of one of the two natural moods, and the open note of the second string of the violin. In the kalendar, it is the first of the dominical letters: among logicians it denotes a universal affirmative proposition: as a numeral, A signified one among the Greeks; but among the Romans it denoted five hundred, and with a short horizontal line over it thus, Ā, five thousand. This letter is often used as an abbreviation. Thus A. A. stands for *Augusti*, A. A. A. for *aurum argentum æs*; and among chemists it signifies *amalgam*. In trials of criminal causes among the Romans, A signified *absolvo*, I acquit, and was hence named litera salutaris, a *saving letter*. When placed to bills of exchange in England it signifies accepted: A. M. stands for *anno mundi*, *in the year of the world*; also for *artium magister*, or *master of arts*; *ante meridiem*, or *before noon*; A. B. *bachelor of arts*: A. C. for *ante Christ*, [illegible]; A. D. fo *anno Domini*; A. A. U. C. for *anno ab urbe condita, the year from the building of Rome*. In physicians' prescriptions $\bar{a}$ or $\overline{a\ a}$ denotes *ana*, an equal weight or quantity of each.

AAM, or Haam, a liquid measure used by the Dutch, containing two hundred and eighty-eight pints English measure.

AB, in the Hebrew chronology, the eleventh month of the civil, and the fifth of the ecclesiastical year, containing thirty days, and comprehending the latter part of July, and the beginning of August.

ABACA, a kind of flax or hemp which grows in the Philippine Islands.

ABACK, a sea term, which signifies the state of the sails of a ship, when, from being full, they are instantly driven flat against the mast by the sudden shifting of the wind, or by a change in the ship's course.

ABACUS, in architecture, signifies the upper part of the capital of a column. In the Tuscan, Doric, and Ionic orders, it is flat and square; but in the other orders, viz. the Corinthian and Composite, its four sides are arched inwards, and embellished in the centre with an ornament, generally a rose, or some other flower. The invention is ascribed to Callima[illegible], who, seeing a small basket covered with [illegible]ile, placed over the root of an acanthus plant, which grew on the grave of a young lady, was so struck with the appearance, that he executed a capital in imitation of it; representing the tile by the abacus, the leaves of the acanthus by the volutes; and the basket by the body of the capital. In ancient architecture the term signifies certain compartments in Mosaic pavements.

Abacus, among ancient mathematicians, was a table strewed over with dust or sand, on which they drew their diagrams.

Abacus, in arithmetic, an instrument for facilitating calculations by means of counters also a table of numbers ready cast up.

Abacus *logisticus*, a kind of multiplication table in the form of a right-angled triangle, each side having the numbers from one to sixty, and the area the product of each two opposite numbers.

ABAFT, in sea language, signifies the situation of any thing placed towards the stern of the vessel; thus *abaft the beam*, is the situation of any object with the ship, when it is in that part of the horizon contained between a line at right angles with the keel, and that point of the compass directly opposite to the ship's course.

ABAGI, or Abasi, a silver coin current in Persia and Georgia, valued at about eighteenpence.

ABALIENATUS, a physical term which, when applied to any part of the body, denotes that it must be cut off; when applied to the senses, it denotes their total destruction.

ABASED, or Abaisse, in heraldry, a term descriptive of the wings of eagles, &c. when the tip inclines downwards to the point of the shield, or when the wings are shut.

ABATE, in law, signifies to break down, or destroy, as to abate a nuisance, and to abate a castle. It means to defeat, or overthrow, in consequence of some error or exception.

ABATEMENT, in heraldly, is an accidental figure added to a coat of arms, to lessen its true dignity, and to indicate some stain in the character of the bearer. In law, it signifies the rejecting a suit on account of some fault, either in the matter or proceeding; and in commerce, it has much the same signification as the term discount. In the excise, it means the usual allowance made in the duty on damaged goods.

ABATIS, in fortification, a term applied to the cutting down of entire trees, and placing them with the branches pointing towards the enemy, to impede their progress.

ABATOR, in law, is an intruder who enters on the possession of an estate to the hindrance of the lawful heir, keeping him out till he brings the writ *intrusione*.

ABB, among clothiers, means the yarn of a weaver's warp; the wool of which it is made is called *abb wool*.

ABBE, a term formerly applied in France to persons who were candidates for church preferment.

ABBESS, the superior of an abbey, or convent of nuns. An abbess exercises the same authority over nuns, that an abbot does over monks, spiritual functions alone excepted.

ABBOT, the superior or governor of an abbey. There are different orders of abbots known by the appellations, mitred, and not mitred, croziered, and not croziered, and œcumenical. The mitred abbots are those who wear the mitre, and exercise episcopal jurisdiction: the croziered are so named from their carrying the crozier, or pastoral staff: and the œcumenical abbots are such as exercise universal dominion. The title is also given to bishops whose sees were formerly abbeys: to the superiors of some congregations of regular canons, as that of St. Genevieve at Paris, and the chief magistrate of the Genoese republic formerly bore the title of abbot of the people.

ABBREVIATION, the contracting of a word or sentence, by omitting some of the letters, or by substituting certain marks or characters in their place. Abbreviations of this sort are used chiefly by lawyers, physicians, and chemists, but most extensively by the Jewish rabbins in their writings.

ABBREVIATORS, a college of seventy two persons in the chancery of Rome, whose business is to prepare the pope's briefs, and reduce his grants in proper form.

ABECEDARY, or Abecedarian, a term sometimes given to schoolmasters, but properly to compositions, the different parts of which are disposed in the order of the letters of the alphabet. This method of writing is chiefly in use among Hebrew writers; and as the Hebrew alphabet consists of twenty-two letters, poems of this kind have only twenty-two lines or systems of lines, or periods; and each line, or period of lines begins with each letter in its order. The following portions of Scripture are specimens of this kind of composition, Ps. cxi. cxii. cxix. Lam: iii.

ABDICATION, the relinquishment of a public office before the term of service is expired. It differs from resignation in this respect, viz. that the latter is done in favour of some other person, whereas the former is done without any such view. Thus Dioclesian abdicated the throne, but Philip IV. of Spain resigned it.

ABDOMEN, the lower part of the trunk of the body, reaching from the thorax to the bottom of the pelvis.

ABDOMINALES, in natural history, an order of fishes having ventral fins placed behind the pectoral in the abdomen, and the branchia ossiculated.

ABDUCTION, in logic, is a form of reasoning called by the Greek *apogogue*, in which the greater extreme is contained in the medium, but the medium not in the lesser extreme. Ex.: whatever God has revealed is certainly true: now God has revealed a future retribution, therefore a future retribution is certainly true. In the use of this kind of reasoning, the minor proposition must be proved to be contained in the major, otherwise the reasoning is inconclusive.

ABDUCTOR, in anatomy, a name given to certain muscles, from their serving to contract or open the parts to which they belong.

ABERRATION, in astronomy, a small apparent motion in the fixed stars, discovered by Mr. Molyneaux, and Dr. Bradley in the year 1725. By the observations of the latter, this phenomenon has been ascertained to arise from the motion of light, combined with the annual motion of the earth in its orbit. The aberration of a planet is equal to its geocentric motion, or that space in which it moves during the passage of light from the planet to the earth.

ABERRATION, in optics, a deviation of the rays of light, when inflected by a lens or speculum, by which they are prevented from meeting in the same point. Aberrations are of two kinds, one proceeds from the figure of the glass or speculum, the other from an inequality in the refrangibility of the rays themselves. This last is called the Newtonian aberration, from the name of the discoverer.

ABETTOR, a term in law, implying one who instigates another to commit a crime. It is the same as the term *art and part* in the law of Scotland.

ABEYANCE, or Abeiance, or Abayance, in law, signifies the expectancy of an estate or possession.

ABJURATION, in law, is a declaration on oath that the pretender, or son of James II. and his issue, have no right to the throne of these kingdoms.

ABLATIVE, in Latin grammar, the name given to the sixth case of nouns; the word is formed from the verb *auferre*, and signifies to take away; it is called by Priscian the *comparative case*, as serving among the Latins for comparing as well as taking away. *Ablative absolute*, is so called because governed by no other word in the sentence.

ABLEGMINA, in Roman antiquity, signify

the chosen parts of the sacrifice, which were always offered to the gods.

ABLUENTS, diluting medicines, or such as dissolve and carry off acrimonious matter from the stomach and intestines.

ABLUTION, a religious ceremony still used in eastern countries, consisting in washing the body before public festivals, or entering the temples. In the Church of Rome the term is applied to the water, with which the priest washes his hands, after consecrating the host: and among chemists it signifies the washing away the superfluous salts of any body.

ABOLITION, in law, denotes the repealing of any law or statute, or prohibiting any custom, ceremony, &c.

ABOLLA, a kind of military garment, worn by the Greek and Roman soldiers, to keep out the cold.

ABOMASUS, ABOMASUM, or ABOMASIUS, in comparative anatomy, names used to designate the fourth stomach of ruminating animals.

ABORTION, in medicine, signifies an untimely or premature birth of a foetus, otherwise called a miscarriage. See MIDWIFERY.

ABOUT, a sea term, signifying the situation of a ship immediately after she has changed her course; in military tactics, it signifies a change in the position of a body of troops.

ABRA, a Polish silver coin of about the value of one shilling.

ABRAUM, a kind of red clay used by cabinet-makers to deepen the colour of new mahogany; it is found in the Isle of Wight, and is sometimes called Adam's earth, from its colour.

ABREAST, a sea term, expressing the situation of two or more ships that lie with their sides parallel to each other; and their heads advanced.

ABRIDGING, in Algebra, is the reducing of a compound equation to a more simple form. See ALGEBRA.

ABRIDGMENT, in literature, signifies much the same thing as an epitome of a large work. The excellence of an abridgment lies in taking only what is material and substantial, and rejecting what is superfluous either in sentiment or style. In law, it is the shortening of a count or declaration.

ABROMA, in botany, a word signifying *not fit for food*, is used to designate a genus of plants of the class and order of polyadelphia dodecandria. There are only two known species, viz. the maple-leaved abroma, which is a tree with a straight trunk, yielding a gum when cut, and filled with a white pith, and is a native of New South Wales, and the Philippine Islands: the other is Wheler's abroma; it is a native of the East Indies, and unknown in Europe.

ABSCESS, in medicine and surgery, an inflammatory tumour containing purulent matter; it is synonymous with apostem, imposthume, and imposthumation, and is the consequence of inflammation.

ABSCISSE, in conic sections, the part of the diameter of a curve line intercepted between the vertex of that diameter and the point where any ordinate or semi-ordinate of that diameter falls. Hence there are numerous abscisses in the same curve, and also numerous ordinates. In the parabola, one ordinate has but one abscisse: in the ellipses it has two; in a hyperbola consisting of two parts it has also two; and in curves of the second and third order, it may have three and four. See CONIC SECTIONS.

ABSCISSION, in rhetoric, a figure of speech by which the orator breaks off suddenly, in the middle of his discourse, to make the deeper impression on his audience.

ABSINTHIUM. See ARTEMISIA.

ABSOLUTE NUMBER, is the known quantity which possesses one side of an equation; thus in $x^2+12x=24$, the absolute number is 24, which is equal to the square of x added to 12 x.

ABSOLUTE EQUATION, in astronomy, the sum of the optic and eccentric equations. The optic equation is the apparent inequality of the motion of a planet; and the eccentric inequality proceeds from the uniformity of the planet's motion.

ABSOLUTION, in civil law, is a sentence whereby the party accused is declared innocent of the crime laid to his charge, and re-[illegible] from all further proceedings. In divi-[illegible] it means the forgiveness of sins, which [illegible]er the Church of Rome claims for the priest; but the Protestants deny it, making their form of absolution merely declaratory.

ABSORBENTS, in the materia medica, are certain medicines that have the power of drying up redundant humours, whether applied to ulcers, or taken inwardly.

ABSORBENT VESSELS, in anatomy, a term applied indiscriminately to the lacteals, the lymphatics, and the inhalent arteries. In botany, it is applied to the fibres of the roots of plants, because they attract and imbibe the nutricious juices from the earth.

ABSORPTION, in chemistry, signifies the conversion of a gaseous fluid into a liquid or solid on being united with some other solid.

ABSTERGENTS, medicines proper for cleansing the body from concretions and other impurities, not to be effected by simple abluents.

ABSTRACT IDEA, among logicians, the idea of some general quality or property considered simply in itself, without any respect to a particular subject. The term is applied to other things to denote their purity or universality. Thus pure, or abstract mathematics, refer to magnitude or quantity, without application to particular objects.

ABSTRACTION, in chemistry, is applied to the process of distillation, in which the volatile products that come over, and are condensed in the receivers, are said to be abstracted from the more fixed parts that remain behind.

ABYSS, a term used to denote, in general any thing profound, or, as the word itself imports, bottomless. In scripture, it is used to denote the deepest parts of the sea, from their being unfathomable; and, in a figurative sense, it signifies the state of the dead, *hell*, or the bottomless pit.

ACACIA, in botany, a name improperly given to several plants as Guilandia, Guiacum, Mimosa, Poincena, and Spartium, which see. In the ancient materia medica, it signified a gum made from the acacia tree, and is supposed to have been the same with our gum-arabic.

ACACIA GERMANICA, a juice made from wild sloes before they become fully ripe; it is moderately astringent, and is given in fluxes and hemorrhages.

ACACIA, or AKAKIA, a roll or bag, represented on the medals of the Greek and Roman emperors, the exact import of which is not known; some supposing it to represent a handkerchief, for giving signals at the public games, others a roll of memoranda, and others bag of earth, to indicate mortality.

ACADEMICS, a term particularly applied by writers to a sect of ancient philosophers, the followers of Socrates and Plato, the distinguishing characteristic of whose system was the uncertainty and incomprehensibility of truth. They have been called sceptics, and, certainly, if the term is applicable to any class of men, it was to them, since they carried their theory so far as to make both extremes meet, by doubting whether they ought to doubt!

ACADEMY, originally signified a place near Athens, surrounded with high trees, and adorned with covered walks, belonging to a person of the name of Academus, or Ecad[illegible] In this place Plato opened his school of philosophy; and, from this circumstance, the term is applied in modern times to all societies, established for the improvement of the arts and sciences.

ACÆNA, in botany, a genus of the tetrandria monogynia class and order of plants. It grows in Mexico, and is about two feet high.

ACALYPHA, or THREE SEEDED MERCURY, in botany, a genus of the monecia monodelphia class. There are fourteen species of it; some annual, and some shrubs; but the plants, having no beauty to recommend them, are not cultivated, and are preserved only in some botanic gardens.

ACHANACEOUS *Plants*, those which are prickly, and bear their flowers and seeds on a kind of head.

ACANTHA, in botany, the prickles of a thorny plant: in zoology, the spines of certain fishes, as the echinus marinus, &c.

ACANTHUS, *Bear's Breech*, in botany, a genus of the didynamia, angiospermia class, and belonging to the natural order of personatæ. Of this plant there are about ten species. In architecture, *acanthus* is an ornament representing the leaves of the herb acanthus, and used in the capitals of the Corinthian and composite orders. See ABACUS.

ACARUS, the tick or mite, a genus of insects of the order of aptera, or those without wings. The acarus is oviparous, and has eight legs; two eyes, one on each side of the head; and two jointed tentacula. It is extremely prolific, and, though voracious, is said to live many months without food. According to Gmelin there are eighty-two species of this insect.

ACATALECTIC, a term in ancient poetry, applicable to such verses as have all their feet and syllables without any defect at the end; those which are not so are called *catalectic*.

ACAULOSE, or ACAULOUS, in botany, a term applied to plants that have no stem.

ACCELERATION, in mechanics, denotes the augmentation or increase of motion in accelerated bodies.

The term acceleration is chiefly used in speaking of falling bodies, or the tendency of heavy bodies towards the centre of the earth produced by the power of gravity; which, acting constantly and uniformly upon them, they must necessarily acquire every instant a new increase of motion.' See GRAVITATION.

ACCELERATOR. See ANATOMY.

ACCENT, among grammarians, is the raising or lowering of the voice in pronouncing certain syllables of words.

We have three kinds of accents, viz. the acute, the grave, and circumflex. The acute accent, marked thus (´), shews that the voice is to be raised in pronouncing the syllables over which it is placed. The grave accent is marked thus (`), and points out when the voice ought to be lowered. The circumflex accent is compounded of the other two, and marked thus (˜ or ˆ): it denotes a quavering of the voice between high and low. Some call the long and short quantities of syllables, accents; but erroneously.

ACCEPTANCE, in common law, is the tacitly agreeing to some act before done by another, which might have been defeated but for such acceptance.

ACCEPTANCE, among merchants, is the signing or subscribing a bill of exchange, by which the acceptor obliges himself to pay the contents of the bill. Bills payable at sight are not accepted, because they must either be paid on being presented, or protested for want of payment.

ACCESSARY, or ACCESSORY, in common law, one who is guilty of a felonious offence, not principally, but by participation. There are two kinds of accessaries; before the fact, and after it. The first is he who commands or procures another to commit felony, and is not present himself: the second is he who receives, assists or comforts any man who has done murder, or felony, whereof he has knowledge. In the lowest and highest offences there are no accessaries, but all are considered as principals.

ACCIACATURA, is a term in music, which denotes the putting down with any interval the half note below it, and instantly taking off the finger which has struck the lowest of the two notes, continuing the sound of the other note till the harmony is changed.

ACCIDENT, denotes in a general sense, any casual event. Among logicians, it signifies, 1. whatever does not essentially belong to a thing; 2. such properties in any subject as are not essential to it; 3. in opposition to substance, all qualities whatever are called accidents; as sweetness, softness, hardness, &c.

In grammar, accident implies, a property attached to a word without entering into its essential definition.

In heraldry it signifies, an additional note or mark in a coat of arms, that may be either omitted or retained without altering the essence of the armour.

ACCIDENTAL, in a general sense, signifies what happens by accident, or that is not essential to its subject. In philosophy it is applied to that effect which flows from some cause intervening by accident, without having the appearance of being subject to general laws.

ACCIDENTAL *point*, in perspective, is that point in the horizontal line where the projections of two lines, parallel to each other, meet the perspective plane

ACCIDENTAL *colours*, are those which depend

on the affections of the eye, in contradistinction to those that belong to the light itself.

ACCIPENSER, in ichthyology, a genus of fishes, belonging to the order of nantes, and class of amphibia, in the Linnæan system. The accipenser has a single linear nostril: the mouth is in the under part of the head, and contains no teeth; the cirri are below the snout, and before the mouth. There are three species of this genus, viz. 1. ACCIPENSER HUSO, with naked body, and four cirri; the skin is so tough as to be made into tackle for drawing carts, and other carriages; and the isinglass of the shops is made from its sounds. The Huso is the largest of the genus, and is found in the Danube, and in some of the rivers of Russia. 2. ACCIPENSER RUTHENUS, has four cirri, and is a native of Russia 3. ACCIPENSER STURIO, or the sturgeon, has four cirri, it annually ascends our rivers, but in no great numbers, and is taken by accident in the salmon-nets. It is found chiefly in the rivers of America, and in the Baltic. Cavier is made of the roes of this fish, and also of the other sorts of sturgeons dried, salted, and packed up close. The sturgeon grows to a great size, and is found sometimes to weigh 500 pounds.

ACCIPITRES, the name of a whole order of birds, the distinguishing characteristic of which is, that they have a hooked or crooked beak.

This order comprehends four genera, viz. the vulture, falco, strix, and lanius kinds; and seventy-two species.

ACCLAMATION, in Roman antiquity, a shout raised by the people to testify their applause, or approbation of their princes, generals, &c. Such is that of Ovid, Fast. 1 613. *Augeat imperium nostri ducis, augeat annos.*

The acclamations of the theatres, which were at first confused and tumultuous shouts, became in process of time a kind of regular concerts. When Nero played in the theatre, a signal was given, and, upon this, 5000 soldiers began to c[illegible]t his praise, which the spectators were obliged to repeat.

ACCOMPANIMENT, in heraldry, denotes any thing added to a shield by way of ornament, as the belt, mantling, supporters, &c.

Accompaniment is also used for several bearings about a principal one, as a saltier, bend, fess, &c.

ACCOMPLICE, in law, a person who is privy to, or aiding in, the perpetration of some crime. See ACCESSARY.

ACCOUNT, or ACCOMPT, in a general sense, is used for all arithmetical computations, whether of time, weight, measure, money, &c. Account is also used collectively, for the books in which merchants, traders, and bankers, enter all their business, traffic, and bargains with each other. See BOOK-KEEPING.

ACCOUNTANT *General*, in the court of chancery, an officer appointed by act of parliament to receive all monies lodged in court, and convey the same to the bank of England, for better security. The salary of this officer and his clerks is to be paid out of the interest made of part of the money; it not being allowable to take fees in this office.

ACCRETION, in natural history, the increase or growth of a body by an external addition of new parts, thus it is salts, shells, stones, &c. are formed.

ACCROCHE', in heraldry, denotes a thing being hooked into another.

ACER, *maple*, in botany, a genus of the monoecia order and polygamia class of plants, and belonging to the natural order of trihilata. There are 25 species. See MAPLE.

ACETATES, in chemistry, a genus of salts formed by the acetic acid. They may be distinguished by the following properties: they are decomposed by heat; the acid being partly driven off, partly destroyed:—they are very soluble in water:—when mixed with sulphuric acid, and distilled in a moderate heat, acetic acid is disengaged:—when they are dissolved in water, and exposed to the open air, their acid is gradually decomposed.

ACETIC *Acid*, is the same which, in a very dilute and somewhat impure state, is called vinegar. In the juice of many plants it is found combined with pot-ash, particularly the sambucus nigra, phœnix dactilifera, galium verum. Sweat, urine, and even fresh milk contain it. The varieties of this acid are four. 1. Wine vinegar; 2. Malt vinegar; 3. Sugar vinegar; 4. Wood vinegar.

ACHANIA, a genus of the monodelphia polyandria class, and the natural order of columniferæ. The essential character is, calyx double; outer many-leaved; corolla convolute; berry five-seeded.

The achania genus includes three species, all exotics, and cultivated (chiefly from cuttings) as stove plants.

ACHILLEA, a genus of plants comprehending the millefolium and patarmica of Tournefort. There are twenty-seven species, only two of which are natives of Britain. It is used in medicine as a sternutatory. A beautiful double variety is cultivated in our gardens, under the name of white bachelor's buttons. The other English milfoil is the yarrow, well known in our meadows.

ACHROMATIC, an epithet expressing a want of colour, introduced into astronomy by De la Lande.

ACHROMATIC. *Telescopes*, formed of a combination of lenses, which in a great measure, correct the optical aberration arising from the various colours of light, are called achromatic telescopes. Some of these have been made wonderfully perfect, and their excellence appears to be limited only by the imperfections of the art of glass-making. The artifice of this capital invention of Dollond consists in selecting, by trial, two such pieces of glass, to form the object lenses, as separate the variously coloured rays of light to equal angles of divergence, at different angles of refraction of the mean ray; in which case it is evident, that, if they be made to refract towards contrary parts, the whole ray may be caused to deviate from its course, without being separated into colours. The difficulty of the glass-maker is in a great measure confined to the problem of making that kind of glass which shall cause a great divergence of the coloured rays with respect to each other, while the mean refraction is small. See OPTICS, and TELESCOPE.

ACHYRANTHES, in botany, a genus of the pentandria monogynia class of plants, belonging to the natural order of miscellaneæ. There are eleven species, but they have but little beauty, and are only preserved in botanic gardens.

ACIA, in botany, a genus of the monadelphia dodecandria class and order: calyx five-parted, five petals, drupe dry, coriaceous, fibrous, one-seeded. Two species, tree sixty feet high, found in Guiana.

ACICULÆ, certain small spikes or prickles, in the form of needles, with which nature has armed several animals, as the hedgehog, the echinus marinus, &c.

ACID, in chemistry, a term originally synonymous with *sour*, and applied only to bodies distinguished by that taste; but it now comprehends under it all substances possessed of the following properties. Acids, when applied to the tongue, excite the sensation of sourness; they change the blue colours of vegetables to a red; they unite with water in almost any proportion; they combine with all the alkalis, and most of the metallic oxides and earths, and form with them those compounds called, in chemistry, salts. Every acid does not possess all these properties, but they all possess a sufficient number to distinguish them from other substances. See CHEMISTRY.

ACIDIFIABLE, capable of being converted into an acid by an acidifying principle. Substances possessing this property are called *radicals*, or acidifiable bases.

ACIDIFIABLE *base*, or RADICAL, is any substance, whether simple or compound, that is capable of uniting without decomposition, with such a quantity of oxygen as to become possessed of acid properties. Almost all the acids agree with each other in containing oxygen, but they differ in their radicals; of course the acidifiable base, or radical, determines the species of acid.

ACIDOTUM, a genus of the monoecia polyandria class and order. The essential character is: male, calyx five-leaved; corolla none; stamina fixed to a globular receptacle. Female, calyx six-leaved; corolla none; style trifid; capsule three-grained. One species only is noted of this plant, which is a native of Jamaica.

ACINUS, a name given to grapes or berries growing in clusters, in opposition to baccæ, or such berries as grow single.

ACLIDES, in Roman antiquity, a kind of missive weapon, with a thong fixed to it, whereby it might be drawn back again.

Most authors describe the aclides as a sort of dart or javelin; but Scaliger makes it roundish, or globular, with a wooden stem to poise it by.

ACNIDA, Virginian hemp, in botany, a genus of the pentandria pentagynia class and order. There is but a single species, viz. A. cannabina, which is a native of Virginia, and some other parts of America; it is seldom cultivated in Europe.

ACONITUM, wolfs-bane, or monk's-hood, a genus of plants of the class and order polyandria trigynia. The essential character is, calyx none; petals five, the highest arched; nectaries two, peduncled, recurved; capsules three or five. There are nine species of this genus, all perennials. It takes its name from its flower resembling in some measure, a man's head with a helmet or hood on it.

ACORUS, in botany, the sweet flag, or sweet rush, a genus of the monogynia order, and hexandria class of plants, and belonging to the natural order of piperitæ. There are two species; the A. calamus grows naturally in shallow standing waters, and is found wild in rivulets and marshy places about Norwich. It is carminative, and stomachic, having a warm, pungent taste, and is frequently used as an ingredient in bitters.

ACORUS, a blue coral, found on the coasts of Africa, from Rio del Re, to the river Camarones. It grows in form of a tree, on a rocky bottom.

ACOUSTICS, is that branch of science which treats of the nature and various modifications of sound. See PNEUMATICS.

ACOUSTIC *Duct*, in anatomy, is the name given to the external passage of the ear. See ANATOMY.

ACQUITTAL, in law, is a deliverance or setting free from the suspicion of guilt; acquittal is either in fact or in law; in fact, it is where a person, on the verdict of a jury, is found not guilty; in law, it is when two persons are indicted, one as a principal, and, the other as accessary: here if the former be discharged, the latter, of consequence, is acquitted.

ACQUITTANCE, a written discharge for a sum of money that has been paid. A man is obliged to give an acquittance on receiving money; and a servant's acquittance on behalf of his master is binding, if that servant used to receive his master's rents.

ACRE, a measure of land containing four square roods, or one hundred and sixty square poles.

The *arpent*, or French acre, is equal to one and a quarter of the English acre. That of Strasburgh is only about one half of the English acre. The Scotch acre is to the English acre, by statute, as 100,000 to 78,694.

We have computations of the number of acres contained in several countries, thus England is said to contain forty-six millions and upwards, and the United Provinces about four and one-third millions.

ACRE-*tax*, a tax levied upon lands, at a certain rate by the acre, otherwise called acre-shot.

ACRID, an appellation given to such matter as is of a sharp and pungent taste.

Ancient naturalists distinguished two kinds of acrid tastes; one proceeding from hot and dry, as in pepper; the other from hot and moist, as in garlic.

ACRIDÆ, in entomology, the name by which Linnæus has distinguished the first family of the gryllus, or the cricket, properly so called: the characters of which are, that the head is conical and longer than the thorax, and the antennæ ensiform, or sword-shaped. Of this family there are eight species, none of which are found in Britain. The insects of this family feed on other insects. See GRYLLUS.

ACROATIC, in the Aristotelian schools, a denomination given to such lectures as were calculated only for the intimate friends and disciples of that philosopher, being chiefly employed in demonstrating some speculative, or abstruse part of philosophy.

ACROBATICA, or ACROBATICUM, in Grecian antiquity, an engine on which people were raised aloft, that they might have the better prospect.

ACROCHORDUS, in natural history, a genus of the class amphibia, and of the order serpents. There are but three species, viz.

A. javanicus, warted snake, brown, beneath paler; the sides obscurely variegated with white. It inhabits Java, chiefly among the pepper plantations; grows sometimes to seven feet long. The warts, by means of a magnifying glass, appear to be convex carinate scales, and the smaller ones are furnished with two smaller prominences, one each side the larger. A. dubius, which very nearly resembles the javanicus, except that the head is covered with very minute, rough, and warted scales, differing in size alone from those on the other part of the animal. A. fasciatus, resembles the dubius so much, that some naturalists suppose them both to be of the same species, and differing only in age and cast of colours.

ACRONICHAL, or Achronycal, in astronomy, an appellation given to the rising of a star above the horizon, at sunset; or to its setting, when the sun rises. Acronichal is one of the three poetical risings of a star; the other two being called cosmical and helical.

ACROSTIC, in poetry, a kind of poetical composition disposed in such a manner, that the initial letters of the verse make some person's name, title, motto, &c.

ACROSTICUM, *rusty-back*, *wall-rue*, or *forked fern*, in botany, a genus of the cryptogamia filices; the character of which is, that the fructifications cover the whole inferior surface of the leaf. There are forty-five species distributed into different classes. Few of the species have been introduced into gardens.

ACT, among logicians, denotes an operation of the human mind; in which sense comprehending, judging, willing, &c. are called acts.

Act, among lawyers, denotes an instrument or deed in writing, to prove the truth of some transaction.

Act, in the *universities*, is a thesis maintained in public by a candidate for a degree. The term when masters or doctors complete their degree is called the act, which is held with great solemnity.

Acts of parliament are called statutes; acts of the Royal Society, transactions; those of the French Academy of Sciences, memoirs; those of the Academy of Sciences at St.Petersburg, commentaries.

ACTÆA, or herb Christopher, a genus of the polyandria monogynia class and order. The essential character is, calyx four-leaved; corolla four-petalled; berry one-celled; seeds semi-orbicular, in two rows. There are four known species of this genus: viz. the spicata; racemosa; japonica; and aspera. The racemosa, or black snake root, found in America, is said to afford an antidote against the bite of the rattle-snake. The leaves of the aspera are used by the Chinese in polishing their tin ware.

ACTINIA, in natural history, a genus of the mollusca order of worms; the characters of which are, body oblong, cylindrical, fleshy, contractile, fixed by the base; mouth terminal, expansile, surrounded with numerous cirri, and without any aperture. There are thirty-six species. These marine animals are viviparous, and have no aperture but the mouth.

ACTION, in mechanics and physics, is the pressure or percussion of one body against another.

It is one of the laws of nature, that action and re-action are equal, that is, the resistance of the body moved is always equal to the force communicated to it; or which is the same thing, the moving body loses as much of its force, as it communicates to the body moved.

Action, in rhetoric, may be defined the accommodation of the voice, but more especially the gesture, of an orator, to the subject he is upon. It is chiefly directed to the passions of the audience.

Action, in law, signifies a demand made before a judge for obtaining what we are legally intitled to demand, and is more commonly known by the name of *law suit*, *process*.

In physiology, action is applied to the functions of the body, whether vital, animal, or natural.

ACTIVE, denotes something which communicates action or motion to another; in which acceptation it is opposed to passive.

ACTOR, in general, signifies a person who acts or performs something, the term is chiefly applied to the person who performs a part in the drama.

ACULEATE, or Aculeated, an appellation given to any thing that has aculei, or prickles: thus fishes are divided into those with aculeated and not aculeated fins.

ACUPUNCTURATION, a name given to a surgical operation in use among the Chinese and Japanese, which is performed by thrusting the point of a gold or silver needle to a certain depth in the part affected. It is chiefly employed in head-aches, convulsions, lethargies, &c.

AD, a Latin preposition, expressing the relation of one thing to another.

It is frequently prefixed to other words thus,

Ad *bestias*, in antiquity, a kind of punishment, which consisted in throwing the criminal to wild beasts.

Ad *hominem*, among logicians, an argument drawn from the professed belief or principles of those with whom we argue.

Ad *libitum*, at discretion; in music, the same with piace, or si piace.

Ad *ludos*, in Roman antiquity, a kind of punishment, whereby the criminals entertained the people, either by fighting with wild beasts, or with each other.

Ad *metella*, in Roman antiquity, the punishment of such criminals as were condemned to the mines, and therefore called metallici. A piece of excellent policy, thus to make the punishment of rogues doubly subservient to the good of the commonwealth.

Ad *valorem*, among the officers of the king's revenue, a term used for such duties, or customs, as are paid according to the value of the goods sworn to by the owner.

ADACTED, in military affairs, is a term applied to stakes or piles, driven into the earth by large malls shod with iron, as in securing ramparts or pontoons.

ADAGIO, softly, leisurely; in music, a term used to denote the slowest of all times, the grave only excepted. Sometimes it is repeated, adagio adagio, to signify a still greater retardation of time.

ADAMANT. See Diamond.

ADAMANTINE *Spar*. This stone, which comes to us from the peninsula of Hither India, and also from China, has not engaged the attention of the chemical world till within a few years past. It is remarkable for its extreme

hardness, which approaches to that of the diamond, and by virtue of which property it is used for polishing gems.

ADANSONIA, in botany, a genus of the monadelphia order, and polyandria class, named after Michael Adanson, an indefatigable French naturalist. The A. digitata, Ethiopean sour-gourd, or monkies' bread, called also abavo, is the only species known of this genus.

ADDER. See Coluber.

ADDITION, in arithmetic, the first of the four fundamental rules of that art, whereby we find a sum equal to several smaller ones.

Addition, in heraldry, something added to a coat of arms, as a mark of distinction or honour, and, therefore, directly opposed to abatement.

Additions, in law, denote all manner of designations given to a man, over and above his proper name and surname, to shew of what estate, degree, mystery, place of abode, &c. he is.

ADDUCTOR, in anatomy, a general name for all such muscles as serve to draw one part of the body towards another. See Anatomy.

ADELIA, in botany, a genus of the dioecia gynandria class and order. Male: calyx three parted; no corolla; stamina numerous; united at the base. Female: calyx five-parted; no corolla; styles three, lacerated. Capsule three-grained.

ADENANTHERA, in botany, a genus of the decandria monogynia class of plants, the calyx of which is a single-leaved perianthium, very small, and cut into five segments: the corolla consists of five lanceolated bell-shaped petals; the fruit is a long membranaceous compressed pod, containing several round seeds.

The seeds are very beautiful, and are used by jewellers as weights, being each of them four grains.

ADFECTED *equations*, in algebra, those wherein the unknown quantity is found in two or more different powers · such is $x^3 - ax^2 + bx = a^2b$.

ADHESION, in philosophy and chemistry, is a term generally made use of to express the property which certain bodies have of attracting to themselves other bodies, or the force by which they adhere together: thus, water adheres to the finger, mercury to gold, &c. Hence arises an important distinction between two words, that in a loose and popular sense are often confounded. Adhesion denotes a union to a certain point between two dissimilar substances, and cohesion that which retains together the component particles of the same mass.

ADIANTHUM, *Maidenhair*, in botany, the name of a genus of plants of the cryptogamia filices class and order, the characters of which are, that the fructifications are collected in oval spots at the ends of the leaves, which are folded back. There are forty-four species, of which one only belongs to Great Britain, viz. the A. capillis veneris, which is found, though rarely, in Scotland and Wales, on rocks and moist walls, and which is a native of the south of Europe and the Levant. From this the syrup of capillaire is made

ADIPOCIRE, or Adipocere, a term applied by chemists to a substance which is formed from animal matter during the changes which it undergoes in its progress towards total decomposition. This matter, says Dr. Ure, very considerably resembles spermaceti. Immense masses of it were found on the removal of the bodies from the burying ground des Innocens, at Paris, 1786 and 1787. Several interesting experiments were made on this substance by Fourcroy, at the time of this discovery, the results of which he laid before the Royal Academy of Sciences, in a memoir which he read in 1789. This memoir is exceedingly interesting; the substance of it is ably detailed in Dr. Ure's Chemical Dictionary, second edition, p. 116.

ADJUTAGE, or Ajutage, in hydraulics, the tube fitted to the mouth of a jet d'eau.

It is through the adjutage that water is played, and directed into any desired figure; so that the great diversity of fountains consists chiefly in the different structure of their adjutages.

ADJUTANT, in the military art, an officer whose business it is to assist the major, and on that account he is sometimes called the aid major.

Adjutant *General*, an officer of distinction, who assists the general in his duty; forms the several details of the duty of the army; and keeps an account of the state of each brigade and regiment. In the day of battle he sees the infantry drawn up: after which he places him[illegible]y the side of the general to receive his

ADMEASUREMENT, in law, a writ for adjusting the shares of something to be divided. Thus, admeasurement of dower takes place, when the widow of the deceased claims more as her dower than what of right belongs to her. And, admeasurement of pasture may be obtained, when any of the persons who have right in a common pasture puts more cattle to feed on it than he ought.

ADMINISTRATOR, in law, the person to whom the goods, effects, or estate of one who died intestate are entrusted; for which he is to be accountable, when required.

ADMIRAL, in maritime affairs, a great officer, who commands the naval forces of a kingdom or state, and decides all maritime causes. For the latter purposes a commissioner has been instituted in England, who, by a statute of W. and M. has the same authority as the Lord High Admiral. The admirals of England are merely naval commanders. Every other business relative to the navy at large is directed by the Lords Commissioners of the Admiralty

ADMIRALTY, properly signifies the office of the Lord High Admiral, whether discharged by one or several joint commissioners, called Lords of the Admiralty.

Admiralty-*Court*, or Court of Admiralty, in the British polity, a sovereign court, held by the Lord High Admiral, or the Commissioners of the Admiralty.

ADMONITIO *fustium*, among the Romans, a military punishment, not unlike our whipping, only that it was performed with vine-branches.

ADONIS *flos*, a genus of plants, called in English pheasant's-eye. It is of the class and order polyandria polygynia: and the essential character is calyx five-leaved; petals, five or more, without a nectary; seeds naked.

The genus includes six species, much resembling the anemone in appearance, only smaller. The adonis autumnalis, an annual plant, is common in our gardens, and even in the field.

about London Its flowers are of a bright scarlet, with a black spot or eye at the bottom. The adonis vernalis is also cultivated in our gardens; but though a native of Switzerland and Germany, we have observed that it is somewhat tender; probably from its shooting so early in the spring: it has a large yellow flower.

ADOPTION, a solemn act whereby one made another his heir, investing him with all the rights and privileges of a son. This practice was frequent among the Greeks and Romans, and is still in use in India and Turkey.

ADORATION, from *ad* to, and *oris* the mouth, denotes the act of worshipping the Supreme Being. This was anciently done by prostrating the body with the face to the earth, as a gesture naturally flowing from the deepest humility of mind; the concealment of the face as the index to the interior operations of the mind, being strongly and most appropriately expressive of the worshipper's total unworthiness so much as to lift up his eyes before the great object of his worship.

ADOXA, in botany, a genus of the octandria tetragynia class of plants, the corolla of which is plain, and consists of a single petal, divided into four oval acute segments. There is but one species, the moschatellina, which is found growing naturally in shady place[illegible]d in woods: the flowers smell like musk.

ADRIFT, in naval affairs, the state of a vessel broken loose from her moorings, and driven to and fro by the winds or waves.

ADSTRICTION, among physicians, is used to denote the too great rigidity and closeness of the emunctories of the body, particularly the pores of the skin; also for the styptic quality of medicines.

ADVANCE, in the mercantile style, denotes money paid before goods are delivered, work done, or business performed.

Advanced-*guard*, or *Vanguard*, in the art of war, denotes the first line or division of an army, ranged or marching in order of battle; or it is that part which is next the enemy, and marches first towards them.

Advanced-*guard* is more particularly used for a small party of horse stationed before the main-guard.

ADVENTURE, *bill of*, among merchants, is a writing signed by a merchant, testifying that the goods mentioned in it to be shipped on board a certain vessel, belong to another per- who is to run all hazards: the merchant only obliging himself to account to him for the produce of them, be it what it will.

ADVENTURER, in a general sense, denotes one who hazards something. By statute 13. Geo. II. c. 4, adventurers may obtain a charter for whatever settlements in America they shall take from the enemy.

ADVERB, in grammar, a word joined to verbs, expressing the manner, time, &c. of an action: thus, in the phrase, *it is conducive to health to rise early*, the word *early* is an ad[illegible]b; and so of others.

ADVERSARIA is more particularly used among men of letters, for a kind of commonplace book, wherein they enter whatever occurs to them worthy of notice, whether in reading or conversation, in the order in which it occurs: a method which Morhof prefers to that of digesting them under certain heads.

ADVERTISEMENT is particularly used for a brief account of an affair inserted in the daily or other public papers, for the information of all concerned, or who may find some advantage from it. By the statute law, the penalty of 50*l.* is inflicted on persons advertising a reward, with "*no questions to be asked*," for the return of things lost or stolen. The same penalty attaches to the printer.

ADUMBRATION, in heraldry, denotes the shadow of any beast or charge outlined, and painted of a darker colour than the field.

ADVOCATE, *advocatus*, among the Romans, a person who undertook the defence of causes, which he pleaded much in the same manner as our barristers do at present.

Advocate, *Lord*, one of the officers of state in Scotland, who pleads in all causes of the crown, or wherein the king is concerned.

The lord advocate sometimes happens to be one of the lords of session; in which case, he only pleads in the king's causes.

ÆDES, in Roman antiquity, signified an inferior kind of temple, consecrated indeed to some deity, but not by the augurs. There were a vast number of these in ancient Rome; thus we read of the *ædes fortunæ, ædes pacis, ædes Herculis*, &c.

ÆDILE, in Roman antiquity, a magistrate whose chief business was to superintend buildings of all kinds, but more especially public buildings; as temples, aqueducts, bridges, &c.

ÆGICERAS, a genus of the class and order of the pentandria monogynia. The essential character is, calyx bell-shaped, half five-cleft, capsule bow-shaped, one-celled, gaping on the convex side; seed inverted. It is found in the Molucca islands, and in Ceylon. There are two species, the majus and minus.

ÆGILOPS, *goat's face*, in botany, a genus of the triandria digynia class and order, and of the natural order of the grasses. There are six species of this grass; all of them seem to be annual. They grow in the south of Europe.

ÆGIPHILA, *goat's friend*, a genus of the tetrandria monogynia class and order, and of the natural order of vitices. There are seven species, natives of the West Indies, chiefly of Jamaica.

ÆGIS, in heathen mythology, is particularly used for the shield, or, according to some, for the cuirass of Jupiter and Minerva.

ÆGLE, in botany, a genus of the polyandria monogynia class and order: calyx five-lobed; petals five; berry globular, many-celled, with numerous seeds in each. One species, viz. the marmelos, a tree with thorny branches; fruit delicious to the taste, and exquisitely fragrant: seeds imbedded in an extremely tenacious transparent gluten.

ÆGOPODIUM, in botany, a genus of the pentandria digynia class of plants. There is but one species, viz. the podagraria, *gout weed*, which is a perennial, creeping weed, with white flowers that appear in May or June. It grows in hedges, and in shady pla[illegible]

ÆNIGMA denotes any dark saying or question, wherein some well known thing is concealed under obscure language.

ÆOLIC *dialect*, among grammarians, one of the five dialects of the Greek tongue, agreeing in most things with the Doric dialect.

Æolic *verse*, in prosody, a kind of verse, consisting of an iambus or spondee, then of two anapests, separated by a long syllable.

ÆOLIPILE, an instrument, mentioned in several philosophical works, as being of great antiquity, although the original use of it seems to be totally unknown. It consists of a hollow metal ball, in which is inserted a slender neck or pipe; whence, after the vessel has been partly filled with water, and heated, issues a blast of vapour, with great vehemence. It has been used by lecturers in natural philosophy to demonstrate the possibility of converting water into an elastic vapour. When used, it is placed on a small carriage, to which it gives motion in a direction contrary to that in which the stream of vapour issues.

ÆOLUS'S *harp*, or ÆOLIAN *harp*, a musical instrument so named from its producing an agreeable harmony merely by the action of the wind.

ÆRA, a fixed point of time, from which any number of years is begun to be reckoned. See CHRONOLOGY.

AEROSTATION, is a term commonly applied to the art of raising heavy bodies into the atmosphere, by the buoyancy of rarefied air, or by gases of small specific gravity enclosed in an envelope, which, from being usually in a spherical form, is called a balloon. Various shapes have been tried; but it has been ascertained that the globular admits the greatest capacity under the least surface, and is, therefore, best fitted for the purpose of aerostation. Balloons are generally made of lutestring, and covered with an elastic varnish, to render the substance impervious by the gas. The weight which they are capable of raising will be in proportion to the diameter of the sphere. From the latest and most accurate calculations, it appears that a cubic foot of hydrogen gas has, by itself, a buoyancy of about one ounce avoirdupois. Hence a balloon of ten feet diameter will have an ascensional force of full 524 oz. or about 33 lbs. *minus* the weight of the material of which it is made; and one of thirty feet diameter, will have a buoyancy of nearly 890 lbs. *minus* the weight of the stuff of which it is made.

In all scientific pursuits, utility ought certainly to be the point of aim. We do not affirm that aerostation never can be rendered essentially subservient to the interests of society; yet it must be confessed that, after numerous attempts, during the lapse of nearly a century and a half, nothing has been effected beyond a few meteorological observations, and the reconnoitering of an enemy's camp from a great altitude in the air, perhaps too great to admit of sufficiently minute observation. The very latest attempts that have been made by aeronauts to ascend into the higher regions seem to have been made chiefly with the view of affording amusement to the public; and, indeed, in its present state, aerostation seems incapable of producing any thing beyond that. Viewing it, therefore, in this light, but, at the same time, as a *scientific amusement*, which, it is hoped, may terminate in some useful discovery, we shall here subjoin a very simple method of constructing an air balloon.

Suppose it be required to construct a balloon of 10 feet in diameter, find by the common rule, the circumference, which will be 31.428, or about 31 feet 5 inches. Divide this by 12, and the quotient will give the width of one of the gores of which the envelope is to be made. To form this gore, draw the line AB, fig. 1, plate 1, of any convenient length; and, about the middle of this line, draw, at right angles with it, the line CD. Then measure off on the line EB from the point E, the distance E f, which must be exactly half the width of the gore; repeat the same on EA, which will give the distance E g, and the points g f will then be asunder the width of the gore. From g, on the line g B, set off towards B 10 times the space g f, and the point B will then be the centre of the segment C g D: with the same radius from the point A describe the segment C f D then C g D f will be the required gore, from which the others may be readily formed. In cutting the gores, about a quarter of an inch more than the breath of the pattern should be allowed all round for the joinings. When the gores are prepared, if it is intended to inflate the balloon with gas, they should be carefully varnished with a solution of caoutchouc in rectified oil of turpentine, in the proportion of one part of the former to thirty-two of the latter; but for rarefied air balloons this is not necessary. In large balloons, the joinings should be sewed, and a warm iron should be passed over the seams to cause the gum varnish to fill up every little imperfection, and render th[illegible]hole air-tight. There must also be a v[illegible] opening inwards fixed in the top of the balloon, pressed close by a spring, for the purpose of letting off the gas when it is required to descend, from which a string must descend into the car where the aeronaut is seated.

With regard to the inflation of the machine, it may be accomplished with very great ease in any town where there is a gas establishment, by inserting into the opening at the bottom a flexible pipe, connected with the nearest convenient part of the main pipe from the gasometer.

When this advantage cannot be commanded, the balloon may be filled with gas produced in the following manner. Into any number of casks, as in fig. 2. plate 1, put a quanti[illegible]f iron chippings, or turnings, the coarser the better; over which pour vitriolic acid, diluted with about seven times its weight of water hydrogen gas will be immediately disengaged in great abundance. The gas may be conveyed by tin or copper tubes from these casks into another of larger dimensions, as B, in which another cask A is to be placed. The vessel B being nearly filled with water, and the tubes from the surrounding casks reaching to the bottom of it, and terminating within the open end of the cask A, the gas will rise through the water, and be collected in A, from whence, by a flexible pipe, it is conveyed directly into the balloon, which, during this process, is suspended by a rope between two upright poles, and the lower part held down by means of heavy weights attached to cords, as seen in the figure. When the inflation is complete, the balloon must be detached from the weights, the suspending cord being dexterously withdrawn, and it will then rise majestically into the air. The car in which the aerial navigators are seated should be made of wicker work, covered with canvass, or leather painted and varnished, and attached to a frame of net work, which must reach about half way down the body of the balloon.

Balloons made of varnished post paper are

sometimes used by philosophical lecturers of a size sufficiently small to be let out, when filled, by the window or door of the lecture-room. These may be filled with gas generated from granulated zinc, and diluted vitriolic acid, in the simple apparatus described by Mr. Cavallo, and represented fig. 3. plate 1, where A is a bottle with the ingredients; BCD a tube fastened in the neck at B, and passing through C, the cork of the other bottle, in which there is a hole made to receive the tube, and to this the balloon is to be tied. Thus the gas, coming out of the tube D, will pass first, through the water in the bottle E, and from thence into the balloon.

It must not be here omitted to notice, that the trouble of preparing small balloons for this purpose is now entirely superseded by an article sold by all mathematical and philosophical instrument makers, prepared from the stomach of the turkey. It may be filled in one minute, and will roll about against the ceiling of the lecture room for a considerable time.

Many of the accounts which are recorded of aerial voyages carry with them a good deal of interest, but in this respect they are all surpassed by that of the French aeronaut M. Garnerin. This gentleman, in September, 1802, ascended alone in his balloon from St. George's Parade, North Audley Street, [illegible] descended soon after into a field near the Small Pox Hospital, St. Pancras.

To the balloon was suspended a parachute, in the manner of a large umbrella when shut, at the extremity of which was a circular basket, wherein M. Garnerin sat. When the balloon was filled, the aeronaut placed himself in the basket, and ascended amidst the applause of innumerable spectators. In about eight minutes, the balloon being at an immense height, M. Garnerin cut the rope, and instantly was disengaged from the balloon in his parachute, which fell rapidly, and, on its expansion, began to vibrate like the pendulum of a clock. Every beholder was alarmed for the safety of M. Garnerin, who, however, landed safely, though he sustained some severe shocks in his descent. Mr. Blanchard appears to have been the first who constructed the parachute, the design of which was to facilitate his descent in case of accident. Fig. 4. plate 1, represents this instrument in its collapsed state, having a small car suspended from the lower part; and fig. 5. shews the same when spread fully out, during the descent.

ÆRVA, in botany, a genus of the monadelphia decandria class and order: the flowers are polygamous, calyx five-leaved, and patent; the stamina are five. There is but one species, which is a native of Arabia.

ÆSCHYNOMENE, or **Bastard Sensitive Plant**, in botany, a genus of the diadelphia decandria class and order, and of the natural order papilionaceæ, of which there are twelve species found native in the East Indies. One of the species is treated as hemp, and used for the same purpose.

This shrub takes its name from a Greek word which signifies *to be ashamed*, because it retreats from the touch.

ÆSCULUS. **The Horse Chesnut**, in botany, a genus of the heptandria monogynia class and order, of the natural order trihilatæ; there are three species, viz. the common horse chesnut, brought originally from Asia into Europe; the yellow flowered horse chesnut, a native of North Carolina; and the scarlet horse chesnut. The wood of the common horse chesnut is chiefly used for water pipes, turner's ware and fuel; it should be felled in November.

The nut has been employed in France and Switzerland for the purpose of bleaching yarn, and is recommended in the Memoir of the Society of Berne, vol. ii. part 2, as capable of extensive use in whitening not only flax and hemp, but silk and wool.

ÆSHUSA, in botany, a genus of the pentandria digynia class and order, and belonging to the natural order of umbellatæ, or umbelliferæ. It is commonly called fool's parsley, or lesser hemlock, which is known to be poisonous; it may be distinguished from common parsley when in flower, but the most effectual method of preventing the bad consequences of mistake, is, to cultivate the curled parsley only.

ÆTNA, a famous volcanic or burning mountain in Sicily, situated on the eastern coast, not far from Catania. The height of this mountain is above 10,000 feet above the surface of the sea, and its circumference at the base is 180 miles. Over its sides are seventy-seven cities, towns, and villages, the number of the inhabitants of which is about 115,000 From Catania to the summit is the distance of thirty miles, and the traveller must pass through three distinct climates, which may be denominated the torrid, the temperate, and the frigid.

AFFIDAVIT is an oath in writing, taken before some person who is legally authorized to take the same.

In an affidavit, the time, place of habitation, and addition, of the person who makes it, are to be inserted.

AFFINITY, among civilians, denotes the relation of each of the parties married to the kindred of the other. Affinity is of three kinds: 1. Direct affinity, or that subsisting between the husband and his wife's relations, by blood; or between the wife and her husband's relations. 2. Secondary affinity, or that which subsists between the above mentioned parties by marriage. 3. Collateral affinity, or that which subsists between the husband and the relations of his wife's relations. The degrees of affinity are always the same with those of consanguinity. In chemistry, affinity signifies that attractive power manifest between the different parts of bodies, whereby they combine with each other.

AFFIRMATION is used for the ratifying or confirming the sentence or degree of some inferior court: thus we say, the House of Lords affirmed the decree of the Lord Chancellor, or the decree of the Lords of Session.

Affirmation also signifies an indulgence granted to the people called Quakers, who, in cases where an oath is required from others, may make a solemn affirmation that what they say is true.

AFFRAY, or **Affrayment**, in law, formerly signified the crime of affrighting other persons, by appearing in unusual armour, brandishing a weapon, &c. But it now denotes a skirmish or fighting between two or more; and there must be a stroke given, otherwise it is no affray.

AFFRONTEE, in heraldry, an appellation given to animals, facing each other on an escutcheon.

AFT, in the sea language, the same with **Abaft**, which see.

AFZELIA, in botany, a genus of the didynamia angiospermia class and order; there is but one species, found in Africa near the equator.

AGAPANTHUS, a genus of the hexandria monogynia class and order, of the natural order of the liliacæ. There is but one species, viz. A. umbellatus or African blue lily. It is a native of the Cape of Good Hope, from whence it was brought to Holland, and in 1692 it was cultivated at Hampton Court.

AGARICUS, in botany, a genus of the order of fungi, and class of cryptogamia; the pillus or cap has gills underneath, and the gills differ in substance from the rest of the plant, being composed of two lamina, and the seeds are in the gills.

There are nearly four hundred species, but of all these one only has been selected for cultivation in our gardens, viz. the campestris. This species is the best and most savoury of the genus; it is eaten fresh either stewed or boiled, and preserved either as a pickle or in powder: and furnishes the sauce called catchup.

The wild mushrooms are found in parks, and other pastures, where the turf has remained long unploughed.

AGATE, a mineral whose basis is calcedony, blended with variable proportions of jasper, amethest, quartz, opal, heliotrope, and carnelian Some species of the agate when cut across and polished, present a beautiful appearance, exhibiting various figures. They were formerly supposed to be produced by deposits of iron or manganese, but it is now thought they arise from mineralized plants of the cryptogamia class.

AGATHOPHYLLUM, a genus of the dodecandria monogynia class and order; calyx very minute, truncate: petals six, inserted into the calyx. There is but one species, viz. the aromaticum, a tree in Madagascar.

AGAVE, in botany, a genus of the hexandria monogynia class and order, of the natural order of coronariæ.

There are seven species, the principal of which is the A. Americana, or great American aloe, whose stems when vigorous, rise upwards of seventy feet high, and branch out on every side, so as to form a kind of pyramid, composed of greenish yellow flowers, which stand erect, and come out at every joint.

The leaves, when pressed, yield a thick juice, which, with lye-ashes, is made up into balls and used instead of soap.

AGE, denotes certain periods of the duration of the world. Thus among Christian chronologers, we meet with the age of the law of nature, which comprehends the time between Adam and Moses; the age of the Jewish Law, which takes in all the time from Moses to Christ; and lastly, the age of grace, or the number of years that have elapsed since the birth of Christ.

AGEMOGLANS, **Agiamoglans**, or **Azamoglans**, in the Turkish customs, Christian children raised every third year, by way of tribute, from the Christians tolerated in the Turkish empire. The collectors of this odious tax used to take one child out of three, selecting always the handsomest.

AGENT, in law, a person appointed to transact the business of another. It is a principle of law, that whenever a man has a power, as owner, to do a thing, he may, as consistent with his right, do it by deputy, either as agent, factor, or servant.

AGERATUM, *maudlin*, in botany, a genus of the syngenesia polygamia æqualis class of plants, with a monopetalous personated flower; and an oblong membranaceous fruit, divided into two cells, which contain a number of minute seeds, affixed to a placenta. There are two species.

AGGREGATE, in botany, is a term used to express those flowers which are composed of parts or florets, so united or incorporated by means either of the receptacle or calyx, that no one of them can be taken away without destroying the form of the whole.

Aggregate, in the Linnæan system of botany, is one of the natural methods of classing plants, and comprehending those which have aggregate flowers.

AGGREGATION, in chemistry, denotes the adhesion of parts of the same kind. Thus, pieces of sulphur united by fusion form an aggregate.

AGIO, in commerce, a term chiefly used in Holland and at Venice, where it denotes the difference between the value of bank stock and the current coin. Money in bank is commonly worth more than specie: thus, at Amsterdam, they give 103 or 104 florins for every 100 florins in bank. At Venice, the agio is fixed at 20 per cent.

AGRICULTURE, is the science which explains the means of making the earth produce, in plenty and perfection, those vegetables which are necessary to the subsistence or convenience of man, and of the animals reared by him for food or labour. Its practice demands an extensive knowledge of the relations subsisting between the most important objects of nature Hence every improvement made in this science must be considered as of high utility. Within the last twenty years, the progress of improvement, in every department of husbandry, has been rapid and extensive beyond all former experience. This has, no doubt, arisen from the laudable zeal with which the arts and sciences have, during that period, been cultivated; for, as it respects the bearing of agricultural pursuits on the interests of society, the motives for improvement must have been always nearly the same.

The limits of this work will not admit of an enlarged view of this subject, important and interesting as it is; nor indeed, is it at all here necessary, since the agriculturist will find the most ample details on every point of real importance in the works of several eminent writers, whose scientific researches, joined to extensive experience, entitle them to a high degree of respect and attention. We shall, therefore, confine this article to such a view of the subject as may prove of general utility.

On Inclosing and Draining. Inclosing of lands may be considered as the grand foundation of all improvements, both as it regards the prevention of litigations between proprietors, and the safety, and even the quality of the produce.

In connexion with inclosures, we may consider the practice of draining lands, as the

next step towards rendering them productive. A superabundance of water [illegible] no less injurious to the land, than the want of it; hence it becomes an object of great importance to the farmer to prevent its pernicious consequences. The formation of the drain must be regulated according to the nature of the soil. Where the open drain is used, care should be taken that it be about three times the width at top that it is at the bottom, otherwise the sides are apt to fall in. Open drains should be cleared once every year.

Where the soil admits the passage of water freely through it the hollow drain may be introduced with success. The usual depth of this drain, is from two feet to two feet and a half, and sometimes three feet. The stones must lean towards each other, so as to form a triangle, the bottom being the base. Stones, however, cannot always be procured; in which case, hollow drains should be filled up with any light open substances that will at once bear up the covering, and permit the water to flow with ease through them. Various substances are recommended for this purpose, such as thick ropes of twisted straw, faggot wood, horn, bones, turf, &c. but, perhaps, the white thorn may be pronounced superior to any thing hitherto used.

FENCES. The principal things to be attended to in the making of fences are, the size of the farm, the degree of exposure, the form of the fields, and the equability of the soil. As to the materials of which fences should be composed, it must be obvious that stone is superior to any thing else. Unless, however, in raising stone fences lime mortar be used, which in many situations is attended with too great an expense to be adopted, there is the unavoidable disadvantage of their going to decay, and in some cases, requiring to be entirely rebuilt once in twenty years.

Next to stone walls, the *white thorn* hedge may be recommended as being extremely durable, and kept up at a very moderate expence when it has been brought to perfection.

The planting of trees in fences, gives a very rich appearance to the landscape; but it is now generally allowed that they are in many respects hurtful to the hedge itself, and also to the crops to a considerable distance on each side; and it is well known how much the highways suffer from their shade.

IRRIGATION. The judicious management of the process of irrigation is of vast importance to the farmer. No one method of improving land brings a more speedy remuneration; the advantage resulting from it, is reckoned to amount to about a guinea per acre.

It is necessary to attend particularly to the facility with which the water can be drawn off the land, since the quicker this can be effected the better.

If the water is allowed to stand on the land too long, a white scum will be observed rising on those parts where it has stagnated, and the warmer the season, the sooner will this occur.

It is the opinion of some, that the clearer the water is that is used in irrigation, the more beneficial are its effects; but experience is directly opposed to this opinion: for every meadow is found productive in proportion to the quantity of mud collected from the water: and so well is this fact now established, that many persons employ labourers, for several days together, to disturb the mud at the bottom of the rivers, that are to supply the meadows with water.

The spring feeding should always be done by sheep, or calves, as the heavier cattle are apt to injure the ground with their feet, while it is soft from the effects of watering.

MANURES. The application of various substances to land, for the purpose of enriching it, has deservedly occupied the attention of some of the most eminent men of science, of which the present age can boast. To enumerate the various species of manure that may be successfully used, would far exceed our limits; we shall therefore only mention the principle, which are these, chalk, lime, shells, bones, gypsum, marl, clay, sand, pond-mud, pond-weeds, ashes, soot, sea-weeds, salt, rape dust, malt dust, yarn, dung, pigeon's dung, rabbit's dung, night soil.

To apply these substances with advantage evidently requires some knowledge of their chemical properties, and also of those of the soil they are intended to benefit. The following remarks of Dr. Ure, are so strictly appropriate to this subject, that we shall give them at length. "When we consider that every change in the arrangements of matter connected with the growth and nourishment of plants; the comparative values of their produce as food; the composition and constitution of soils; and the manner in which lands are enriched by manure, or rendered fertile by the different processes of cultivation, we shall not hesitate to assign to chemical agriculture a high place among the studies of man. If land be unproductive, and a system of ameliorating it is to be attempted, the sure method of attaining this object is by determining the causes of its sterility, which must necessarily depend upon some defect in the constitution of the soil, which may be easily discovered by chemical analysis. Some lands of good apparent texture are yet eminently barren; and common observation and common practice afford no means of ascertaining the cause, or of removing the effect. The application of chemical tests in such cases is obvious; for the soil must contain some noxious principle which may be easily discovered, and probably easily destroyed. Are any of the salts of iron present? They may be decomposed by lime. Is there an excess of siliceous sand? The system of improvement must depend on the application of clay and calcareous matter. Is there a defect of calcareous matter? The remedy is obvious. Is an excess of vegetable matter indicated? It may be removed by liming, paring, and burning. Is there a deficiency of vegetable matter? It is to be supplied by manure. Peat earth is a manure; but there are some varieties of peats which contain so large a quantity of ferruginous matter as to be absolutely poisonous to plants. There has been no question on which more difference of opinion has existed, than that of the state in which manure ought to be ploughed into land; whether recent, or when it has gone through the process of fermentation. But whoever will refer to the simplest principles of chemistry, cannot entertain a doubt on the subject. As soon as dung begins to decompose, it throws off its volatile parts, which are the most valuable and most efficient. Dung which has fermented so as to become a mere soft cohesive mass, has generally lost from

one-third to one-half of its most useful constituent elements."

THE CULTURE OF GRASSES. The purposes for which grass lands are required are two; *first*, for affording hay, and when laid out for this purpose they are called meadows; *secondly*, for the growing of herbage for the support of cattle, they are then termed *pastures*. When ploughed lands are to be laid down for meadow or pasture, the soil should be thoroughly pulverized by ploughing and harrowing; the seeds should be sown after some hoeing crop, as turnips, or cabbages; damp weather is the most suitable for the purpose; and the seed can hardly be sown in too great abundance. To form a good turf, requires much labour and attention; and when once produced, it ought never to be broken up without the certain prospect of advantage by the change.

An agriculturist of great eminence has given the following arrangement of grasses adapted to the different soils.

Clay.	*Loam.*	*Sand.*
Cow grass,	White clover,	White clover,
Cock's-foot,	Rye,	Rye,
Dog's-tail,	York white,	York white,
Fescue,	Fescue,	Yarrow,
Fox-tail,	Fox-tail,	Burnet,
Oat grass,	Dog's-tail,	Trefoil,
Trefoil,	Poa,	Rib.
York white,	Timothy,	
Timothy	Yarrow,	
	Lucerne.	

Chalk.	*Peat.*
Yarrow,	White clover,
Burnet,	Dog's-tail,
Trefoil,	Cock's-foot,
White clover,	Rib,
Sainfoin.	York white,
	Rye,
	Fox-tail,
	Fescue,
	Timothy.

In our meadow and pasture lands we find a great variety of grasses, of which some are far more valuable than others; to know the good from those which are indifferent becomes the interest of the farmer; we therefore give him the characters of the most valuable.

1. Great smooth stalked meadow grass—Poa pratensis.
2. Hard fescue grass—Festuca duriusculo.
3. Meadow fescue grass—Festuca pratensio
4. Ray grass—Lolium perenne.
5. Meadow fox-tail grass—Alopecurus pratensis.
6. Sheep's fescue grass—Festuca ovina.
7. Rough stalked meadow grass—Poa trivialis.
8. Marsh meadow grass—Poa palustris.
9. Com[illegible] meadow grass—Poa compressa.
10. Crested dogs' tail grass—Cynosurus cristatus.
11. Knotty cats' tail grass—Phleum nodosum.
12. Sweet scented spring grass—Anthoxanthum odoratum.

Great or smooth-stalked meadow grass. This grass is considered as the best of all we have; it is early in its foliage, makes the best hay, affords the richest pasture, all sorts of cattle are fond of it. it is in all our meadows, and will continue in the same land much longer than any other grass.

Hard fescue. This is an early and productive grass, wi[illegible]e foliage, which grows well on downs and rich meadows. It is well adapted for being combined with other grasses in forming sheep pastures, and stands high in esteem as a very good hay grass.

Meadow fescue grass. This is a grass that comes near in its appearance to rye grass, but to which it seems greatly superior, as being larger, and more productive of foliage. It is strictly perennial and hardy, thriving well in most soils, growing in all situations; and it abounds in the best meadows, in the best hay districts; is sweet, luxuriant, and quick of growth, affording rich pasture, and making good hay.

Ray or rye grass. This is a sort of grass that has been much in cultivation, but is deficient in some of the properties necessary for meadow or pasture lands. In rich moist meadows its foliage is abundant; and it seems probable that it is highly acceptable and nutritious in feeding cattle; its foliage is of rapid growth, and flowering stems continually shooting forth. It is best adapted to the loamy and sandy descriptions of soils; but it will succeed on any except stiff clay, and even on that it may be grown.

Meadow fox-tail grass. It is in some measure distinguished by the largeness of its foliage, which is rather coarse, and by its producing a soft spike on a long stalk, early in May. If it be mown early, just as it comes into bloom, the hay will not be coarse. It shoots very rapidly after mowing, and produces a plentiful aftermath.

Sheep's fescue. This grass is praise-worthy both for the purposes of pasture and hay; sheep and other sorts of stock are fond of it, and are soon rendered fat in pastures where it prevails, giving to mutton a sweet delicious flavour.

Rough-stalked meadow grass. It delights in moisture, and situations that are sheltered; on which account, though there are few more productive, or better adapted for the purpose of hay or pasturage, it is tender, and liable to be injured by severe cold or drought; and in moist rich ground it has been observed to grow tall, while in poor land it has been found equally diminutive. It is well adapted to sound, moist loams; and the produce is excellent for all sorts of cattle.

Marsh meadow grass. This is a fine exuberant grass, and one of the best dairy grasses we have. It grows in all our rich marshes, which are subject to be flooded in winter; and rises in general, to the height of four feet.

Compressed meadow grass. This is an excellent grass for parks and sheep walks, deer and sheep being remarkably fond of it; it makes a fine turf, and renders the flesh of the animals short, and well flavoured.

Crested dogs' tail grass. This grass grows best in dry pasture land, and will not thrive in meadows that are very moist. Its thick tufts afford much food for sheep in the time of snow, and severe weather in the winter season. Its growth being rapid, it should be cut down quickly.

Knotty cats' tail grass, is a fine exuberant grass, very fit for dairy pastures, and for cow-hay. It produces abundance of milk; and cattle are very fond of it.

Sweet scented vernal grass. This grass comes early into blossom; it may be raised on almost any soil, but in point of crop it is not quite so productive as some other grasses. It is the only grass of this climate which is odoriferous; the agreeable scent of new made hay being produced almost entirely by it.

INSTRUMENTS AND OPERATIONS OF HUSBANDRY.—The instruments used in husbandry are so numerous, and, under the same denomination, often so differently constructed, with a view to varieties of the same operation, that it would be impossible in a sketch like the present to detail their structure and application. In the process for which they are respectively intended, every agriculturist will of course avail himself of those, the utility of which is best decided by experience.

PLOUGHING.—In almost all lands there is a fixed depth for the plough to go to, which is the stratum between the fertile and unfertile moulds. No soil should be ploughed beyond this bottom, or sole, which is the preservative on which the top layer should rest, and by which the manure laid upon the ground is prevented from losing its effect. In fallowing land, therefore, the plough may go as deep as the fertile soil will allow, as also in breaking up land without paring and burning. When land is pared and burnt, it ought to be ploughed in small furrows, and not so deep, as this depth of furrow would hazard the loss of the ashes for the immediate, and indeed for the subsequent crops.

Stubble ought never to be ploughed into the land; it is much better to mow it, and even to harrow the land before it is fallowed.

It is necessary to observe a due proportion between the depth of the ploughing, and the quantity of manure usually spread; ploughing before harrowing will always be found of great consequence in fallow grounds.

Fallows ought always to be kept very clean; indeed this must be attended to at all events, whatever other business may demand the attention of the husbandman.

Harrowing is necessary both for covering the seed, and for preparing the land for its reception. In the construction of the harrow, great care should be taken that the teeth be placed so as that no one tooth shall follow the tract of another. Harrowing is best performed by going over a square piece at a time, so that the harrow may be lifted at the corner, and the refuse stuff left there.

Till of late years the practice of rolling was but little used, or even known, and it is in many places exercised so slightly, as to be of little service. Its utility, when it is exercised as it ought to be, consists in rendering a loose soil more compact and solid, which, by making the earth adhere to the roots of plants, cherishes their growth. No roller that can be drawn by two, or even by four horses, will carry this effect too far. By rolling, moreover, the moisture of the earth is kept more in, and, in a dry season, this circumstance may reasonably be presumed sometimes to constitute the difference between a good and a bad crop. The common practice of breaking clods by means of mallets may judiciously be superseded by the roller, preceded for a day or two by harrowing.

For grass lands it is obvious that the mowing for hay is [illegible]ly facilitated by rolling.

What is termed scarifying of grass lands is used by a variety of persons, and is directly opposite, in its principle, to that of rolling them.

For this purpose, a plough, consisting only of coulters, or narrow teeth, is employed; and it is asserted, that the crops of hay are considerably increased by the loosening of the earth occasioned by this process, the roots acquiring the power of fresh vegetation. The operation may undoubtedly be beneficial in various instances and soils. The use of the roller, however, upon grass lands of a certain description will be admitted to be preferable.

BROADCAST AND DRILL HUSBANDRY.—There are three methods of sowing seeds in use. The *first,* which is the oldest method, is called the *broadcast system;* by this method the seeds are scattered by the hand, over the surface of the ground; *secondly,* the seeds may be dropped at equal distances and in straight rows; this is called the *drill system; thirdly,* small holes are made in the ground, and the seed dropped into them by the hand: this method is called dibbling.

The broadcast system, which is still much practised, is liable to many serious objections. It is impossible, even with the greatest care, and the most extensive experience, to scatter the seed so that an equal quantity shall fall on every part of the surface.

The grain must sometimes fall from the hand in heaps, and in this case part of it must perish; it will likewise be harrowed in at various depths; and with the greatest care, part of it will remain a prey to birds. The consequences of such irregularity must be too obvious to require remark, and yet the system is persevered in by many, from mere prejudice against modern improvements.

In the drill husbandry, no more seed is committed to the ground than what is likely to spring up, and the whole is almost certain to come to maturity. The advantages of the drill system are these: 1. The seed is disposed in equidistant rows. 2. It is deposited at a fixed depth. 3. In any given portion of each row, it is very nearly the same in quantity. By the first of these the method of horse hoeing is obtained· the second secures the uniform growth of the crop; and by the third, the seeds are prevented from injuring each other by their proximity, while there is no loss of ground by the want of a greater quantity of seed.

Dibbling is performed thus. After the land has been prepared by ploughing, harrowing, and rolling, a man having in each hand a staff, about three feet long, pointed with iron, makes two holes at once, as he moves backwards, taking care to keep the successive holes as nearly as possible in a straight line, and at regular distances. Two or more children attend him, and drop two, three, or four seeds into each hole.

These are afterwards covered in by passing a light harrow over the land. This system may be practised with advantage, where the state of the land is too rugged to admit of the drill. The expenditure of seed by this method is so small, that three pecks of wheat will serve for an acre.

ROTATION OF CROPS.—Various causes operate to render the alternation of crops an indispensable part of successful husbandry. As soils are exhausted of those principles which are neces-

sary to the growth of any particular crop, by the unintermitted succession of it; the most effectual means of relieving the soil, and of obtaining from it the maximum of produce, is found to consist in such a rotation of crops as will draw from it different principles, or different quantities of the same principles.

Thus white crops, such as wheat, oats, &c., are extremely exhausting, but afterwards the soil will bear a good crop of beans, turnips, or tares.

The following rotation of crops has been recommended by an eminent and experienced agriculturist, where the turnips, peas, and beans, are put in double rows on three-feet ridges: the cabbages, in single rows of three-feet ridges; and the whole hoed and cleaned with the utmost care.

Clay.	*Clayey loams.*
Turnips or cabbages,	Turnips or cabbages,
Oats,	Oats,
Beans and clover,	Clover,
Wheat,	Wheat,
Turnips or cabbages,	Turnips or cabbages,
Oats,	Barley,
Beans and vetches,	Beans,

Wheat,	Wheat,	Clover and rye-grass,
Potatoes,	Potatoes,	Clover and rye-grass,
Barley,	Barley,	Peas,
Peas,	Peas,	Wheat or rye.
Wheat.	Wheat.	

REAPING AND STORING.—When artificial grasses are to be turned into hay, they should be treated in a manner different from that adopted with regard to natural ones. They ought to be allowed to lie in swarth for a day or two; after which, being turned with care, they should lie a day or two longer; by this simple process the hay is, in good weather, sufficiently made. After remaining two days in cocks, these should be carried to the stacks.

The mowers should cut the grass as low as possible, and five makers are not too many for every mower. The grass should be shaken out immediately after the scythe. By the evening it should be raked into rows. The next morning it should be again shaken and spread, and in the evening it should be put up into cocks. These being opened on the following morning, after a similar process, may, in fine weather, be safely collected into the great hay-cock at night. If successive rains come on to damage it, as it is stacked, a peck of salt should be strewed in layers on every load. The stack should be covered within a week after it is finished. To preserve as much of the sap of grass as possible, without incurring the danger of firing, is the grand practical problem of hay-making.

When the stems of culmiferous plants are totally divested of green, they are perfectly ripe. Wheat has been immemorially reaped; but barley, when the ground has been smoothed by rolling, may be cut down with the scythe. Cutting of corn in wet weather, ought ever to be avoided if possible. Barley is particularly subject to injury by wet. Peas grow so irregularly as to make the sickle necessary. Instead of housing corn, stacking is a far superior practice, as it not only, by the consequent exposure to the air, carries what is called a finer countenance, but as it is more completely preserved from vermin. Every sheaf should be made to incline downward, from its top to its bottom. The best form for a stack is that of a cone, placed upon a cylinder. The moment a stack is finished, the covering of it should commence.

THRESHING.—The usual mode of threshing, is attended with the inconvenience of the straw being very often not thoroughly cleared, by which, much grain is lost; and with that of affording the workmen great and perpetual incentives to depredation, which, perhaps, are rarely resisted, or, at least, are certainly often yielded to. A fixed threshing mill will give comparative security against these evils; and one worked by two or three horses may be purchased for from sixty to a hundred guineas, and which, in eight hours, will thresh fifteen quarters of wheat. The granary should be over this mill, and the corn may then, immediately after threshing, be drawn up into it, and deposited safe under the key of the farmer. Fresh threshed straw is better than old for feeding cattle, and is best managed for them by being cut into chaff.

FRUIT TREES.—The cultivation of fruit trees for the purpose of deriving from their juice a fermented liquor, employs a great proportion of the land of this as of other countries, and is, on that account, an important branch of agricultural attention.

The varieties of apples are entirely artificial, nature having only provided one species which is the crab. Apple trees should be cleared of redundance of wood, as it very much intercepts the free circulation of the air. They should be kept clear also of the misletoe, which often proves highly injurious to them; neither should moss be permitted on any account to incumber them.

As general management, with respect to orchard grounds, it is a judicious rule to plant for such, a broken-up worn-out sward, keeping it under arable, until the trees have attained tolerable growth, when it may, with advantage, be laid down to grass, and be permitted to remain in that state, till the trees are finally removed.

PLANTATIONS.—In planting timber trees it is of importance to suit the tree to the situation and soil, and at the same time to avoid making any uncertain sacrifice to obtain a thriving produce. The proper season for planting commences in October, and may be continued throughout the winter if the weather prove mild. In transplanting trees, the north side should be marked, and every tree should have the same aspect in its new situation as before, otherwise its growth will be checked. The

oest form for a plantation is that of a circle, as presenting the least surface of any figure for its area, and, consequently, this form will have the fewest outside trees, which are always stunted in their growth, at least more so than those which are more central.

The oak is generally found to thrive best in hilly situations, where there is a rich black soil. It is propagated by acorns, of which from four to six bushels are used on an acre; seeds of furze should be sown along with them to protect the young oaks from cold winds, and from rabbits.

The beech is also raised from seed; it delights in a calcareous or chalky soil. In exposed situations, Scotch firs are planted to shelter it, and afterwards cut down.

The elm is usually propagated from seed, or by suckers taken from the roots of old trees: it grows quickest on light soils, but produces the best wood on stiff soils.

The larch will grow on almost any soil, and in any situation; it will even flourish where other trees can hardly live, provided it has depth of root. It is of all resinous trees the most valuable on an estate, and makes a greater return than any other tree.

For Scotch firs a light sandy soil is the most suitable: it grows most rapidly, and attains the greatest height on the north and east sides of hills.

The birch and hazel may be raised in almost any situation; the ash requires a light, rich, calcareous soil: the poplar requires a moist soil, and thrives best by the banks of rivers: the willow is admirably suited for wet, marshy land; and in a few years its culture becomes exceedingly profitable.

Coppices are reckoned fit for cutting, in about fourteen years; and the proper season for felling, is from November till about the end of March, but not later, except for trees which are to be barked, for which May is the best month.

CATTLE.—Under this head the horse is the first subject of attention to the agriculturist. The following description of the horse best suited for agricultural purposes is truly excellent; it is from the treatise on *Live Stock*, by Culley.

"His head should be as small as the proportion of the animal will admit; his nostrils expanded, and muzzle fine; his eyes cheerful and prominent; his ears small, upright, and placed near together; his neck, rising out from between his shoulders, with an easy tapering curve, must join gracefully to the head; his shoulders, being well thrown back, must also go into his neck (at what is called the points) unperceived, which, perhaps, facilitates the going much more than the narrow shoulder; the arm, or fore thigh, should be muscular, and, tapering from the shoulder, meet with a fine, straight, sinewy, bony leg; the hoof circular, and wide at the heel; his chest deep, and full at the girth; his loin or fillets broad and straight, and body round; his hips or hooks by no means wide, but quarters long, and tail set on, so as to be nearly in the same right line as his back; his thighs strong and muscular; his legs clean, and fine-boned; his leg-bones not round, but what is called lathy or flat."

When corn is given to horses it should be previously bruised, as the grains which they swallow whole, lie undigested in the stomach, which will not act on the husk. The bruising is best done by the machine called the crushing machine, which bruises every grain that passes through it. Corn thus prepared will yield one fourth more nourishment than uncrushed grain.

The practice of soiling horses, instead of turning them to grass in summer, is allowed to be an excellent means of reducing the expense of keeping them, without either impairing their condition, or diminishing their capability of working. Turnips, carrots, and potatoes, afford an excellent winter food for horses, when green food cannot be obtained.

The horses best adapted to the general purposes of husbandry, are principally of three breeds: viz. the *Cleveland bays*, the *Suffolk Punches*, and the *Clydesdale horses*.

Black cattle, intended for feeding, should be chosen for their being short legged, which quality is almost uniformly connected with a general good make. Straightness of back another important recommendation, and the more perfectly straight they are, while at the same time, they are very broad and flat on the loins, the more readily experienced judges will decide on their worth. Smallness of dewlap, and the barrel form of carcase, both in the fore and hind quarters, are also justly insisted upon as points of excellence. A curled hide is indicative of a thriving beast, and worthy of observation in the choice of these animals. A still more favourable symptom is a softness or sleekness of skin. Indeed the nice touch of the hand is requisite in the judge of cattle, perhaps, nearly as much as the keen observation of the eye. Oxen that have been worked are more valuable to graziers than others, as not only fattening with greater rapidity, but furnishing more excellent beef. After working till the age of fourteen years, which is within two of the usual extent of their natural life, they have often supplied most tender and admirable meat.

When cattle become swelled by eating too much succulent food, they may be effectually relieved by being driven about for some time with great rapidity; but a still more successful method is to stab them with a knife, to the depth of four inches, between the ribs and the hip bone. A flexible tube also is sometimes passed through the mouth into the gullet, by which the air is discharged which causes the disease.

The value of a cow as a milker, should be determined not by the quantity of milk she affords, but by the quantity of cream which the milk yields.

SHEEP.—In the management of sheep, the different breeds must be adapted to the soil and situation where they are kept. The most common breeds are, the *new Leicester*, or *Dishley breed*, with long wool, having hairs, barrel shaped bodies, small heads, and an aptness to fatten early. The *Teeswater* breed of sheep; these are larger than any other; the ewes generally bring two or three lambs in a season, but this breed is only adapted to a soil that is warm, and highly fertile. The *black-faced*, or *Scotch sheep*, are best suited for bleak and mountainous tracts; they are small; their wool is very coarse, but their flesh is sweet, and the most scanty food will supply their necessities. The other breeds are, the Lincolnshire, the Romney-marsh, the Herefordshire, the South Down, and the Merino

or Spanish breed, &c. The lambing should be contrived to be in March, or early in April; The greatest difficulty attending this kind of stock is the supplying of suitable provision at this season, for if the growth of the lamb be checked, the evil is irremediable. The *rouen*, or after-grass, is the most valuable article in this case, as it is very wholesome, and much relished. Turnips also afford a good supply, and increase the quantity of the milk of the ewes; but a little hay should be given along with them.

Sheep that are kept in inclosures, and particularly in a woodland country, should be examined twice every day, to guard against injury to them from the fly, which in twenty-four hours after having struck, sometimes produces incurable disease. The most efficacious treatment on this subject is, after parting the wool wherever the maggots are found, and picking them out with a knife, to scrape a small quantity of white lead among the wool, so that it may be carried evenly down to the wound. Regular and minute inspection will prevent such a circumstance as a broken coat in any of these animals, from a cause so dangerous and fatal where they are neglected.

When ewes about to lamb, their keep should be of the most nourishing kind, consisting of plenty of turnips or cabbage. Till this period they may do without them. But all cattle that have young require as good keeping as those which are fatting. The turnips or cabbages should be drawn for them, and given them on dry gound. A standing rack of hay should be left for them on the field, which will be of great advantage to them.

Swine.—By proper management, swine may be rendered an important source of profit to the farmer; they are very prolific, and may be kept at little expense, since they consume immense quantities of food that would not be of any value to any other kind of live-stock. breeds are of different kinds, which vary much in size; the larger kinds should be kept only where provision of the best kind can be had in abundance. As the sow has two litters in the year, these ought to be so regulated as to have them both in mild weather; winter litters are not worth the trouble of rearing. Swine will fatten on almost any sort of food; and when corn is given them to prepare them for the market, it should be ground into meal, and mixed with water.

Soiling of swine is found to be highly advantageous, from the quantity of manure it produces; and although they are the filthiest of all animals, yet cleanliness is highly conducive to their health: warmth also is beneficial to them.

Poultry are more or less a part of the stock of almost every farm, and when they are reared with a view to profit, and on a large scale, they will be found to repay the great attention necessary to bring them to maturity.

A house should be erected for them, containing divisions appropriately for roosting, sitting, fatting, and food. The building should be constructed near the farm-yard, having clear water contiguous to it. Warmth and smoke are great cherishers of poultry. All, of every species, must have access to gravel and grass. Their cheapest food consists of boiled potatoes, on which it appears that they can be supported and fattened, without the aid of any corn. Where numbers of them are kept upon a farm, if permitted to go at large, they will often do considerable injury both in the fields and barn-yard, besides which they will be extremely exposed to the attacks of vermin, and will lose a considerable number of their eggs. A full-grown hen continues in her prime for three years, and may be supposed in that time to lay 200 eggs, which number, however, by warmth and nourishment, might be greatly exceeded.

The quality and size of the Norfolk turkeys are superior to those of any other part of the kingdom. They are fed almost entirely with buck-wheat, which, perhaps, may account for their excellence, and are bred by almost every little farmer in the county. When young, they demand perpetual attention, and must be fed with alum, curds, and chopped onions, and the expense attending their management and food can be compensated only where broods are tolerably successful, and the prices high.

The Dairy.—In selecting those cows which are most suited for the dairy, respect must be had, not so much to the quantity of milk which they give as to the quantity of cream which the milk affords.

The richest milk known is produced by cows of the Alderney breed. Much skill is required in managing a breed of milk cows; and none should be entrusted with the milking of them but those who can be fully depended on; an artful mildness of management, with a soft hand, and gentle touch, will render the operation of milking agreeable to the cow, the milk will flow freely to the last drop. This tender management will not only secure the continuance of the quantity of milk drawn at any particular time, but will even improve it; whereas if from want of skill a portion of the milk be left in the udder, the cow will eventually become dry. The usual practice is, to milk cows twice a day; but in the summer season when they have an abundance of succulent food, they may be milked three times.

The situation of a dairy is of importance. It ought to be well aired, yet as well shaded as possible; and its windows should never front the south, the south east, or south-west. Every utensil should be kept most scrupulously clean; hence a plentiful supply of water is indispensable.

The temperature of about fifty-five degrees is most favourable for the separation of the cream from the milk. The utensils of the dairy are best made of wood; lead and copper being soluble in acid, and highly pernicious; and though iron is not injurious, yet the taste of it renders the produce of the dairy unpalatable.

AGRIMONIA, *agrimony*, in botany, a genus of the dodecandria digynia class and order. Of this genus there are five species; the A. parviflora is found in the corn-fields and hedges in Britain, and in most parts of Europe it is perennial, and flowers in June and July. It is used in medicine as a cure for the jaundice: the Prussians use it for dressing leather.

AGROSTEMA, *the garland of the field*, in botany, a genus of the decandria pentagynia class and order. There are four species, viz. 1. A. githago, corns campion, or cockle. 2. A. coronaria, rose campion: 3 A flos Jovis; and 4. A. cœli rosa, smooth campion.

AGROSTIS, a genus of triandrious plants, called in English bent grass. It is of the class and order triandria digynia; the essential character is, calyx bivalve, one-flowered, a little less than the corolla; stigmas longitudinally shaped.

There are no less than thirty-five species of this grass; most of them are foreign, and some only annual. About eight species are enumerated as natives of Britain.

A-GROUND, expresses the situation of a ship, the bottom of which rests on the ground.

AGRYPNIA, denotes much the same with watchfulness, or an aptitude to sleep; which is a very troublesome symptom of feverish, and other disorders.

Agrypnia, in the Greek church, the vigil of any of the greater festivals.

AGUE, a general name for all intermittent fevers, which, according to the different times of the return of the feverish paroxysm, or fit, are denominated quotidian, tertian, or quartan agues.

AGYNEIA, in botany, a genus of the triandria monogynia class and order; there are but two species of this shrub, both natives of China.

A-HULL, denotes the situation of a ship when all her sails are furled, on account of the violence of a storm, and when having lashed her helm to the lee side, she lies nearly with her side to the wind and sea, her head being somewhat inclined to the direction of the wind.

AIGUISCE', Aiguisse', or Eguisce', in heraldry, denotes a cross with its four ends sharpened, but so as to terminate in obtuse angles. It differs from the cross fitchee, inasmuch as the latter goes tapering by degrees to a point, and the former only at the ends.

AILANTHUS, the tree of heaven, so called on account of its lofty growth; a genus of tree, the class and order of which are not ascertained: some accounting it polygamia monoecia, and some dioeccia decandria. It has male, female, and hermaphrodite flowers. It is a native of China, but grows very fast in our climate, and is recommended for ornamental plantations.

AIR, is a subtile, invisible, elastic fluid, surrounding the globe of the earth. It was formerly believed to be an elementary principle, but the researches of philosophy have long since exploded this theory, and it is now well known that this fluid is a compound of various ingredients, but consisting chiefly of two gases, viz. oxygen and azote.

For a more particular description of air, see the articles, Atmosphere, Gas, Chemistry, and Pneumatics.

Air-*Balloon.* See Aerostation.

Air-*Gun.* See Pneumatics.

Air-*Jacket*, a sort of jacket made of leather, in which are several bags, or bladders, of the same materials, and communicating with each other. These are all filled with air by means of a tube of leather, having a brass stopcock at the extremity. The use of the air-jacket is to support a person in water who is unable to swim.

Air-*Pipes*, an invention for drawing foul air out of the holds of ships, or any other place; the invention is ascribed to Mr. Sutton, a brewer in London, whence they are called Sutton's pipes. The principle on which their action depends is no other than that air is necessary for the support of fire; and if it has not access from the places most adjacent, will readily come from those that are more remote. Hence the fire kept up in a ship, for the necessary purposes, may be employed to consume all the foul air that may at any time be collected about the vessel.

Air *Pump.* See Pneumatics.

Air *Threads*, in natural history, a name given to the long filaments so frequently seen in Autumn, floating about in the air. These threads are the work of spiders, especially of the long legged field spider.

Air *Vessels*, are spiral ducts in the leaves of plants, &c. supposed to be analogous to the lungs of animals, in supplying the different parts of the plants with air.

AITONIA, in botany, so named from Mr. Aiton the late king's gardener at Kew, a genus of the monadelphia octandria class and order, and of the natural order of columniferae. There is but one species, a native of the Cape of Thunberg.

AJUGA, in botany, a genus of the didynamia gymnospermia class of plants: the flower is monopetalous and ringent, the upper lip being rather small and bifid; the lower one is large and trifid; no pericarpium; the seeds are contained in the cup of the flower: there are ten species.

AIZOON, in botany, a genus of the polyandria pentagynia class: there are ten species of this plant, all natives of hot countries, they may be raised in this country on hot beds, but they are not remarkable, either for beauty or any other property.

ALABASTER, a species of stone which has a greater or less degree of imperfect transparency, a granular texture; is softer and tal a dull polish than marble, and is usually of a white colour.

Alabaster is found in Germany, France, and Italy; it is used by sculptors for statues; and has sometimes been used in large thin slabs for windows, on account of its readily transmitting the rays of light. There is hurch at Florence illuminated in this way.

ALÆ, in anatomy, is sometimes used for the lobes of the liver, the nymphæ of the female pudendum, the two cartilages which form the nostril, the armpits, young stems or branches, &c.

ALATED, in botany, an epithet applied to the seed, stem, or leaf stalk: a seed is alated, when it has an ala or membrane affixed to it, which, by its flying, serves to disperse it.

ALAUDA, Lark, in ornithology, a genus of birds of the order of passeres; the characters of which are, that the beak is cylindrical, subulate, and straight, bending towards the point; the mandibles are of equal size, and opening downwards at their base; the tongue is bifid; and the hinder claw is straighter and longer than the toe.

Pennant observes that the nostrils are covered with feathers or bristles, and the toes divided to their origin. There are thirty three species; the principal are; -1. The A. arvensis, or sky-lark This bird and the wood-lark are the only birds which sing flying. The higher it flies, the more

it strains its voice, and, in descending, it lowers it until it quite dies away. 2. The A. pratensis or titlark. This bird has a remarkably fine voice, and frequents meadows. 3. A. arborea the woodlark, is distinguished by an annular belt of white encircling the head. It haunts uncultivated tracts near copses, but seldom penetrates the woods. 4. A. campestris, the meadow lark, it differs from the others by the blackness of its bill and feet; it inhabits heaths, and uncultivated tracts; and frequently oat-stubble, where birds of this species are often found to assemble in great numbers. 5. A. trivialis, the voice of this bird is weak, and resembles the cry of chickens: it builds its nest in solitary spots, concealed under turfs, hence its young frequently become a prey to adders. 6. A. cristata, or crested lark; this bird is found in most parts of Europe; it lives in the meadows and fields, on the sides of ditches, and on the backs of furrows. This is the only lark that may be instructed; in a month it learns many airs perfectly, which it repeats without confusion.

ALBINOS, the name by which the Portuguese call the white Moors, who are looked upon by the negroes as monsters. They, at a distance, might be taken for Europeans; but, upon a near inspection, their white colour appears like that of persons affected with a leprosy.

ALBUCA, a genus of the hexandria, monogynia class and order. The essential character is, corolla six petalled, inner ones difform, stamina three of the six castrated stigma, surrounded by six carps. There are eight species rather tender, but may be kept in winter in a garden frame.

ALBUMEN, in chemistry, a term to denote the white of egg, and all glary, tasteless substances, which, like it, have the property of coagulating into a white, opaque, tough, solid substance, when heated a little under the boiling point. This substance forms a constituent of many of the fluids of animal bodies, and when coagulated, it constitutes also an important part of their solids. Substances analogous to it have been noticed in the vegetable kingdom. The essential characters of albumen are the following: 1. In its natural state it is soluble in water, and forms a glary, limpid liquid, having very little taste: in this state it may be employed as a paste and a varnish. 2. The solution is coagulated by acids, in the same way as milk is acted upon; and also by heat of the temperature of 170°, and by alcohol. 3. Dissolved in water, it is precipitated by the infusion of tan; and also in the form of white powder by the salts of most of the white metals as silver, mercury, lead, and tin. 4. When burnt, it emits ammonia, and when treated with nitric acid, yields azotic gas.

ALCA, or Auk, in ornithology, a genus of the order of anseres. The beak of this genus is without teeth, short, convex, compressed, and frequently furrowed transversely: the inferior mandible is gibbous near the base; the feet have generally three toes. There are 12 species of the alca, of which the most remarkable are,

1. The impennis, northern penguin. 2. The alca, little auk. 3. The arctica, or puffin. 4. The torda, or razor bill. 5. The pica, or black-billed auk. 6. The cirrhasa, or tufted auk. 7. The psittacula, or parroquet auk.

ALCEA, The holly-hock, in botany, a genus of the monadelphia polyandria class of plants. It grows wild in the country of Nice: the colours of the holy-hock flowers are accidental; and the double flowers are varieties proceeding from culture. Gmelin enumerates five species of this plant: viz. the A. ficifolia, the rosea, the semensis, the acaulis, and the Coromandeliana.

ALCEDO, or Kingsfisher, in ornithology, a genus of the order of picæ. The alcedo has a long, straight, thick, triangular bill; with a fleshy, plain, short, flat tongue. Of this genus there are many species, with one or other of which almost every part of the world is furnished. Most of them frequent rivers, and live on fish, the singularity of catching which is admirable: sometimes hovering over the water, where a shoal of small fishes is seen playing near the surface; at other times waiting with attention, on some low branch hanging over the water, for the approach of a single fish which is so unlucky as to swim that way; in either case dropping like a stone, or rather darting with rapidity on its prey; when, seizing it cross-wise in its bill, it retires to a resting place to feast on it; which it does piecemeal, bones and all, without reserve, afterwards bringing up the indigestible parts in pellets, like birds of prey. The wings of most of the genus are very short; yet the birds fly rapidly and with great strength. It may be remarked, that throughout this genus, blue, in different shades, is the most predominant colour. There are above thirty species of this genus of birds according to some; others enumerate forty one.

ALCHEMILLA, or Ladies-mantle, a genus of the moongynia order, and terandria class of plants; and in the natural method ranking under the 35th order, senticosæ. The essential character is cal. 8 cleft, cor. none, seed one. There are 4 species; the principal are:

1. A. Alpina, or cinque-foil ladies-mantle. It is a native of the mountainous parts of Europe.

2. A. minor, or least ladies-mantle. It grows naturally in Sweden, Lapland, and other cold countries.

3. A. vulgaris, or common ladies-mantle, with leaves plaited like a fan, and yellowish green blossoms. It grows naturally in pasture lands in this as in most other other countries in Europe.

ALCHEMY, (from *al*, the, Arab, and χημια, chemistry,) that obsolete branch of chemistry which had for its principal objects the transmutation of metals into gold; the panacea or universal remedy; an alkahest, or universal menstruum; a universal ferment; and many other things equally ridiculous.

There is a remark by Mr. Gurney in his introductory Lecture, relating to this subject, which is worthy of notice, as being highly illustrative of the character of the clergy in every age.

"During the period at which the study of alchemy was most prevalent, it was professedly regarded as a high, and almost sacred art, fit only to be known and practised by the pure, the learned, and the wise. It was studied by the clergy more than by any other set of men

and such of the sacred edifices as now remain to us belonging to that period, exhibit numerous symbols and hieroglyphics of the art. In this country, in particular, many of the prelates of Westminster are known to have been adepts: and the abbey itself remains to this day not without allegorical symbols connected with this practice."

ALCHORNIA, a genus of the dioecia monodelphia class and order. The essential character is, male, calyx three, five-leaved; cor. none: female, calyx five-toothed, cor. none, styli two parted, caps. berried, decorous. There is one species, of which little seems to be known in this country.

ALCOHOL, commonly called *spirit of wine*, is obtained by distillation in a state more ardent and purified than that article. Spirit of wine is obtained by distilling farinaceous or sacharine roots, as well as the pulpy fruit of vegetables; it is purified by repeated rectification, and is called *alcohol* when digested of its aqueous particles. It is chiefly employed in preparing varnishes, in dissolving gum resins, and for various other purposes in medicine. The antiseptic power of alcohol renders it valuable in preserving anatomical preparations. It is also now much used for burning in lamps on account of the steady and uniform heat which it gives during combustion. Fourcroy reckons it to be rectified to the highest point when its specific gravity is 829, water being 1000.

It was long supposed that alcohol could not be solidified by congelation; but it appears from an account given by Dr. Hutton, in the Edinburgh Encyclopedia, that he succeeded in freezing it by a cold of 110°: the process, however, has not been made public.

ALCOR in astronomy, a small star adjoining the bright one in the middle of the tail of Ursa Major.

ALCORAN. See KORAN.

ALDEBARAN, in astronomy, a star of the first magnitude, called in English the Bull's-eye, being the eye of the constellation Taurus. Long. $6^{\circ}\ 32'\ 9''$ of Gemini. Lat. $5^{\circ}\ 29'\ 40''$ S.

ALDER, in botany. See Betula.

ALDERMAN, among our Saxon ancestors, was a degree of nobility answering to earl or count at present. It ranked inferior to atheling, but superior to thane. Alderman was also used in the time of king Edgar, for a justice or judge. In modern British policy, it implies a magistrate subordinate to the mayor of a city or town corporate. The number of these magistrates is not limited, but is greater or less according to the magnitude of the place. In London they are twenty-six; each having one of the wards of the city committed to his care. The office is for life.

ALDROVANDA, in botany a genus of the pentandria pentagynia class and order, of which there is only one species, viz. the A. vesiculosa, found in marshes in Italy and India, with bladders like utricularia, but in bunches.

ALE-*conner*, an officer in London, who inspects the measures of public-houses. They are four in number, and chosen by the common-hall of the city.

ALECTRA, in botany, a genus of the didydamia angiosperma class and order, of which there is a single species only, viz. A. capensis, a native of the Cape of Good Hope, found in grassy places near rivers, flowering in November and December.

A-LEE, in sea-language, a term only used when the wind, crossing or flanking the line of a ship's course, presses upon the masts and sails so as to make her incline to one side, which is called the lee-side: Hence, when the helm is moved over to this side, it is said to be *a-lee* or *hard-a-lee*

ALEMBIC, a vessel formerly used in distilling. They were usually made of glass or copper. The bottom, which contained the subject for distillation, was called, from its shape, the cucurbit; the upper part, which received and condensed the stream, was called the head, the beak being fitted into the neck of a receiver. Retorts, and the common worm-still, are now more generally employed.

ALETRIS, in botany, a genus of the monogynia order, and hexandria class of plants; and in the natural method ranking under the tenth order, coronariæ. There are nine species, viz. 1. A. farinosa, or American aletris. 2. A. capensis, a native of the Cape of Good Hope. 3. A. hyacinthoides. 4. A. Zeylanicia, or Ceylon aloe. 5. A. fragrans, or true aloe. 6. A. glauca, a native of the Cape. 7. A. uvaria, or great orange flowered aloe. 8. A. pumila. 9. A. Conchinchensis.

ALEXANDRIAN *manuscript*, a famous copy of the New Testament. This MS. is now preserved in the British Museum. It was sent as a present to king Charles I. from Cyrillus Lucaris, patriarch of Constantinople, by Sir Thomas Rowe, ambassador from England to the Grand Signior, about the year 1628. Cyrillus brought it with him from Alexandria, where probably it was written. In a schedule annexed to it, he gives this account: That it was written, as tradition informed him, by Thecla, a noble Egyptian lady, about 1300 years ago, not long after the council of Nice. But this high antiquity, and the authority of the tradition to which the patriarch refers, have been disputed; nor are the most accurate biblical writers agreed about its age.

A fac simile of this valuable work was published in 1786 by Dr. Woride, with types cast on purpose.

ALGÆ, Flags, one of the seven families, or natural tribes, into which the whole vegetable kingdom is divided by Linnæus, in his Philosophia Botanica. They are defined to be plants, whose root, leaf, and stem, are all one. Under this description are comprehended all the seaweeds, and some other aquatic plants. In the sexual system they constitute the third order of the twenty-fourth class *cryptogamia*, and the fifty-seventh order in Linnæus's Fragment of a Natural Method.

ALGEBRA. The term Algebra, although evidently Arabic, seems to be of rather uncertain derivation, the most probable supposition is, that it is derived from *al* and *geber*, which, when joined, signifies *the reduction of fractions to a whole number*. It is however, applied by the moderns, to express the process of that particular branch of the science of mathematics which teaches the method of performing calculations by means of the letters of the alphabet, together with a few other symbols, which will be explained in the following definitions.

To give here an enlarged view of even the rudiments of Algebra, would be inconsistent with our plan; at the same time, it will be necessary to enter so far into it, as to enable the student to consult, with advantage, the most modern and popular treatises on this important branch of mathematical science.

DEFINITIONS.

1. Known quantities are generally represented by the first letters of the alphabet, as, a, b, c, &c. Unknown, by the last; as, x, y, z.

2. The sign $+$ (*plus* or more) is the mark of addition. Thus, $a+b$ means that the quantities represented by a and b are to be added together. When no sign is prefixed, $+$ is understood.

3. The sign $-$ (*minus* or less) denotes subtraction; as $a-b$, that is, the number represented by b is to be subtracted from that represented by a.

4. Quantities with the sign $+$ prefixed, are called positive or affirmative; and those with the sign $-$ negative quantities.

The sign $\times$ (or, multiplied by) denotes multiplication: as 5×4 means that 5 is to be multiplied by four.

6. $\div$ is the mark of division; thus, $a\div b$ means that a is divided by b.

7. A number prefixed to a letter is called a numeral coefficient. When no number is expressed, 1 is understood.

8. A simple quantity consists of one part or term; as $+a$, $-abc$; a compound quantity of more than one, connected by the signs $+$ or $-$; as, $a+b$, $a-b+c$, are compound quantities. If there are two terms, it is called a *binomial*, if three, a *trinomial*, &c.

9. Like quantities consist of the same letters repeated: thus $+ab$, $-5ab$, are like quantities; but $+ab$, and $+a^2b$ are unlike quantities.

10. The powers of algebraic quantities are expressed by placing a *small figure* (equivalent to the number of factors, and called the index or exponent of the power) at the right hand side of the letter. Thus $a\times a$, or the square of a is expressed by a^2; $b\times b\times b$, or the cube of b, is expressed by b^3; $x\times x\times x\times x$, or the fourth power of x, is expressed by x^4; $\overline{a+b}\times\overline{a+b}\times\overline{a+b}$, or the cube of $a+b$, is expressed by $\overline{a+b}|^3$, and so on.

11. The *roots* of quantities are expressed by the sign $\surd$, with the proper index annexed: thus $^2\surd a$, or $\surd\overline{a}$ expresses the square root of a; $^3\surd b$, the cube root of b; $^4\surd\overline{a+x}$, expresses the biquadrate root of $a+x$, &c.

12. The sign $=$ placed between two or more quantities, expresses the *equality* of such quantities; thus, $a+b=c+d$, means that $a+b$ is equal to $c+d$; and $ax+by=cx+dy=ex+fy$, mean that the quantities $ax+by$, $cx+dy$, and $ex+fy$, are all equal to each other.

13. In algebraical operations the word *therefore*, or *consequently*, often occurs. To express this word the symbol $\therefore$ is commonly used; thus, the sentence; "therefore, $a+b$ is equal to $c+d$," is expressed by $\therefore a+b=c+d$.

14. The symbol $>$ placed between two unequal quantities signifies that the first is greater than the last, thus $a>b$, intimates that a is greater than b; but when the character is inverted, it signifies, that the first quantity is less than the second; thus $a<b$, intimates that a is less than b.

ADDITION.

Case 1. To add quantities that are alike, and have like signs.

Rule. Add the coefficients together, to their sum join the quantities, and prefix the common sign.

$$\begin{array}{rr}
\text{Ex. 1.} & \text{Ex. 2.} \\
2x+3a-4b & 7x^2+3xy-5bc \\
3x+2a-5b & 9x^2+2xy-7bc \\
4x+8a-7b & 11x^2+5xy-4bc \\
9x+4a-6b & x^2+4xy-bc \\
\underline{5x+7a-9b} & \underline{x^2+9xy-2bc} \\
23x+24a-31b & 29x^2+23xy-19bc
\end{array}$$

Case 2. To add quantities that are like, but have unlike signs.

Rule. Subtract the lesser coefficient from the greater, prefix the sign of the greater to the remainder, and subjoin the common letter or letters.

$$\begin{array}{rr}
\text{Ex. 1.} & \text{Ex. 2.} \\
4x^2-3x+4 & -7ab+3bc-xy \\
-2x^2+x-5 & -ab+2bc+4xy \\
3x^2-5x+1 & 3ab-bc+2xy \\
7x^2+2x-4 & -2ab+4bc-3xy \\
\underline{-x^2-4x+13} & \underline{5ab-8bc+xy} \\
11x^2-9x+9 & -2ab\ \star\ +3xy
\end{array}$$

Case 3. To add terms that are unlike.

Rule. Set them all down one after another with their signs and coefficients

$$\begin{array}{lr}
\text{Ex.} & -3x^2 \\
 & -11x^3 \\
 & 6a^2 \\
 & -7e \\
 & -9b^4 \\
 & \underline{12c} \\
\multicolumn{2}{r}{-3x^2-11x^3+6a^2-7e-9b^4+12c}
\end{array}$$

SUBTRACTION.

General Rule. Change all the signs of the quantities to be subtracted into their contrary signs, and add them to the others by the preceding rules; which will give the difference or remainder.

$$\begin{array}{llr}
\text{Ex. 1.} & \text{From} & 6a-12b \\
 & \text{take} & \underline{-5a-10b} \\
 & \text{Ans.} & 11a-2b \\
\text{Ex. 2.} & \text{From} & 5a^2+4ab-6xy \\
 & \text{take} & \underline{11a^2+6ab-4xy} \\
 & \text{Ans.} & -6a^2-2ab-2xy \\
\text{Ex. 3.} & \text{From} & 4a-3b+6c-11 \\
 & \text{take} & \underline{10x+a-15-2y} \\
 & \text{Ans.} & 3a-3b+6c-10x+2y+4
\end{array}$$

MULTIPLICATION.

Rule for the Signs. If the signs of the two terms are like, that of the product is $+$, but if unlike, it is $-$.

Case 1. To multiply two terms.

Rule. Find the sign of the product by the general rule; then place after it the product of the numeral coefficients, and the letters one after another.

Example.

$$\begin{array}{lll}
\text{Mult.} & a & +5b \\
\text{By} & \underline{b} & \underline{-3c} \\
 & ab & -15bc
\end{array}$$

Case 2. To multiply compound quantities.

Rule. Multiply each term of the multiplicand, by the terms of the multiplier, and collect the products into one sum.

Examples.

$$\begin{array}{ll} \text{Mult.} & 3ab-2ac+d \\ \text{By} & 4a \\ \hline \text{Ans.} & 12a^2b-8a^2c+4ad \end{array}$$

Ex. Mult.

$$\begin{array}{lccccc} & a^2+2ab+b^2 & & & & \\ \text{By} & a^2-2ab+b^2 & & & & \\ \hline & a^4 & +2a^3b & +a^2b^2 & & \\ & & -2a^3b & -4a^2b^2 & -2ab^3 & \\ & & & +a^2b^2 & +2ab^3 & +b^4 \\ \hline \text{Ans.} & a^4 & * & -2a^2b^2 & * & +b^4 \end{array}$$

DIVISION.

The same rule for the signs is to be observed in Division as in Multiplication; that is, if the signs of the dividend and divisor are like, the sign of the quotient must be +; if they are unlike, the sign of the quotient must be —. This will be easily deduced from the rule in Multiplication, if you consider that the quotient must be such a quantity as, multiplied by the divisor, shall give the dividend.

The general rule in Division is, to place the dividend above a small line, and the divisor under it, expunging any letters that may be found in all the quantities of the dividend and divisor, and dividing the co-efficients of all the terms by any common measure. Thus, when you divide $10ab+15ac$ by $20ad$, expunging a out of all the terms, and dividing all the co-efficients by 5, the quotient is $\frac{2b+3c}{4d}$.

Powers of the same root are divided by subtracting their exponents, as they are multiplied by adding them. Thus, if you divide a^5 by a^2, the quotient is a^{5-2}, or a^3. And b^6 divided by b^4, gives b^{6-4}, or b^2; and a^7b^5 divided by a^2b^3, gives a^5b^2 for the quotient.

If the quantity to be divided is compound, then you must range its parts according to the dimensions of some one of its letters, as in the following example. In the dividend $a^2+2ab+b^2$, they are ranged according to the dimensions of a, the quantity a^2, where a is of two dimensions, being placed first, $2ab$, where it is of one dimension, next, and b^2, where a is not at all, being placed last. The divisor must be ranged according to the dimensions of the same letters; then divide the first term of the dividend by the first term of the divisor, and set down the quotient, which in this example is a; then multiply this quotient by the whole divisor, and subtract the product from the dividend, and the remainder will give a new dividend, which in this example is $ab+b^2$.

Ex. 1. If $a^2-2ab+b^2$ be divided by $a-b$, the operation will be as follows:

$$\begin{array}{rl} a-b) & a^2-2ab+b^2\ (a-b \\ & a^2-ab \\ \hline & \quad -ab+b^2 \\ & \quad -ab+b^2 \\ \hline & \quad\ \ * \quad\ * \end{array}$$

Ex. 2.

$$\begin{array}{rl} 1-x) & 1 \quad (1+x+x^2+x^3+\&c.+\frac{\text{Remainder}}{1-x} \\ & 1-x \\ \hline & \ +x \\ & \ +x-x^2 \\ \hline & \qquad +x^2 \\ & \qquad +x^2-x^3 \\ \hline & \qquad\qquad +x^3 \\ & \qquad\qquad +x^3-x^4 \\ \hline & \qquad\qquad\qquad +x^4,\ \&c. \end{array}$$

Ex. 3.

$$\begin{array}{rl} y-1) & y^3-1\ (y^2+y+1 \\ & y^3-y^2 \\ \hline & \quad +y^2+1 \\ & \quad\ \ y^2-y \\ \hline & \qquad +y-1 \\ & \qquad\ \ y-1 \\ \hline & \qquad\quad * \end{array}$$

FRACTIONS.

PROB. 1. *To reduce a Mixed Quantity to an Improper Fraction.*

RULE. Multiply the part that is an integer by the denominator of the fractional part; and to the product add the numerator; under their sum place the former denominator.

Thus $2\frac{3}{5}$, reduced to an improper fraction, gives $\frac{13}{5}$; $a+\frac{a^2}{b}=\frac{ab+a^2}{b}$; and $a-x+\frac{a^2-ax}{x}=\frac{a^2-x^2}{x}$.

PROB. 2. *To reduce an Improper Fraction to a Mixed Quantity.*

RULE. Divide the numerator of the fraction by the denominator, and the quotient shall give the integral part; the remainder set over the denominator shall be the fractional part.

Thus, $\frac{12}{5}=2\frac{2}{5}$; $\frac{ab+a^2}{b}=a+\frac{a^2}{b}$; $\frac{ax+2xx}{a+x}=x+\frac{x^2}{a+x}$; $\frac{aa+xx}{a-x}=a+x+\frac{2xx}{a-x}$.

PROB. 3. *To reduce Fractions of different Denominators, to Fractions of equal Value that shall have the same Denominator.*

RULE. Multiply each numerator, separately taken, into all the denominators but its own, and the products shall give the new numerators. Then multiply all the denominators into one another, and the product shall give the common denominator. Thus,

The fractions $\frac{a}{b}$, $\frac{b}{c}$, $\frac{c}{d}$, are respectively equal to these fractions, $\frac{acd}{bcd}$, $\frac{b^2d}{bcd}$, $\frac{c^2b}{bcd}$, which have the same denominator bcd. And the fractions $\frac{2}{3}$, $\frac{3}{4}$, $\frac{1}{5}$, are respectively equal to these $\frac{40}{60}$, $\frac{45}{60}$, $\frac{12}{60}$.

PROB. 4. *To add and Subtract Fractions.*

RULE. Reduce them to a common denominator, and add or subtract the numerators; the sum or difference set over the common denominator, is the sum or remainder required.

Thus, $\frac{a}{b}+\frac{c}{d}+\frac{d}{e}=\frac{ade+bce+d^2b}{bde}$; $\frac{a}{b}-\frac{c}{d}=\frac{ad-bc}{bd}$; $\frac{2}{3}+\frac{3}{4}=\frac{8+9}{12}=\frac{17}{12}=1\frac{5}{12}$; $\frac{3}{4}-\frac{2}{3}=\frac{9-8}{12}=\frac{1}{12}$; $\frac{4}{5}-\frac{3}{4}=\frac{16-15}{20}=\frac{1}{20}$; $\frac{x}{2}-\frac{x}{3}=\frac{3x-2x}{6}=\frac{x}{6}$.

PROB. 5. *To Multiply Fractions.*

RULE. Multiply their numerators one into another to obtain the numerator of the product; and their denominators multiplied into one another, shall give the denominator of the product.

Thus, $\frac{a}{b}\times\frac{c}{d}=\frac{ac}{bd}$; $\frac{2}{3}\times\frac{4}{5}=\frac{8}{15}$.

PROB. 6. *To Divide Fractions.*

RULE. Multiply the numerator of the divi-

dend by the denominator of the divisor, their product shall give the numerator of the quotient. Then multiply the denominator of the dividend by the numerator of the divisor, and their product shall give the denominator. Thus,

$$\frac{4}{5}\Big)\,\frac{2}{3}\,\Big(\frac{10}{12};\quad \frac{3}{7}\Big)\,\frac{5}{8}\,\Big(\frac{35}{24};\quad \frac{c}{d}\Big)\,\frac{a}{b}\,\Big(\frac{ad}{cb};$$

$$\frac{a+b}{a+b}\Big)\,\frac{a-b}{a}\,\Big(\frac{a^2-2ab+b^2}{a^2+ab}$$

Prob. 7. *To find the greatest common measure of two numbers.*

Rule. Divide the greater number by the less, and the last divisor by the last remainder; continue this process until nothing remains, and the divisor last used will be the common measure required.

Thus, to find the greatest common measure of a^2-b^2 and $a^2-2ab+b^2$,

$$a^2-b^2)\ a^2-2ab+b^2\ (1$$
$$\underline{a^2-b^2\qquad\qquad}$$
$$-2ab+2b^2 \text{ remainder,}$$

which divided by $-2b$ is reduced to

$$a-b)\ a^2-b^2\ (a+b$$
$$\underline{a^2-b^2}$$
$$*\quad *$$

Therefore $a-b$ is the greatest common measure required.

Prob. 8. *To reduce a fraction to its lowest terms.*

Rule. Find the greatest common measure by the last problem. Divide both terms of the fraction by the common measure thus found, and it will reduce it to its lowest terms.

Thus $\frac{a}{b}$ being given, and it being required to reduce it to an equal fraction whose denominator shall be c; find the quotient of ac divided by b, and it shall be the numerator of the fraction required.

INVOLUTION.

Involution is the raising of any quantity to a given power, and is performed by continual multiplications of that quantity into itself, till the number of factors amounts to the number of units in the index of the given power.

Thus, the *square* of $a = a^2 = a\times a$: the *cube* of $b = b^3 = b\times b\times b$; the *fourth* power of $2 = 2\times2\times2\times2 = 16$; *the fifth* power of $3 = 3\times3\times3\times3\times3 = 243$.

If the quantity proposed be a compound one, the involution may either be represented by the proper index, or it may actually take place.

Let $a+b$ be the quantity to be raised to any power.

$$\begin{array}{rl}
 & a+b \\
 & \underline{a+b\qquad} \\
 & a^2+ab \\
 & \quad\ \underline{+ab+b^2} \\
\overline{a+b}|^2 \text{ or } & a^2+2ab+b^2 \text{ the sq. or } 2^{d} \text{ power} \\
 & \underline{a+b\qquad\qquad} \\
 & a^3+2a^2b+ab^2 \\
 & \quad\ \underline{+\ a^2b+2ab^2+b^3} \\
\overline{a+b}|^3 \text{ or } & a^3+3a^2b+3ab^2+b^3 \text{ the } 3^{d} \text{ power} \\
 & \underline{a+b\qquad\qquad\qquad\qquad} \\
 & a^4+3a^3b+3a^2b^2+ab^3 \\
 & \quad\ \underline{+\ a^3b+3a^2b^2+3ab^3+b^4} \\
\overline{a+b}|^4 \text{ or } & a^4+4a^3b+6a^2b^2+4ab^3+b^4
\end{array}$$

the fourth power

EVOLUTION.

Evolution, is the reverse of involution, or it is the method of finding the square root, the cube root, &c. of any given quantity, whether simple or compound.

The roots of single quantities are easily extracted by dividing their exponents by the number that denominates the root required. Thus, the square root of a^4 is $a^2 = a^{\frac{4}{2}}$; and the square root of $a^4\,b^6\,c^2$ is $a^2\,b^3\,c$. The cube root of $a^6\,b^3$ is $a^{\frac{6}{3}}\,b^{\frac{3}{3}} = a^2\,b$; and the cube root of $x^9\,y^6\,z^{12}$ is $x^3\,y^2\,z^4$. The ground of this rule is obvious from the rule for Involution.

To extract the root of a compound quantity.

Rule. Range the quantity according to the power of some letter, as in division. Find the root of the first term, and set it in the quotient. Subtract the square of the root thus found from the first term, and bring down the next two terms to the remainder for a dividend, and take double the root already found for a divisor. Divide the dividend by the divisor, and annex the result both to the quotient and the divisor. Multiply the divisor thus increased by the term last put in the quotient, subtract the product from the dividend, and bring down the next two terms to the remainder; proceed thus until the work is finished.

Examples.

Required the square root of $a^2+2ab+b^2$

$$\begin{array}{rl}
 & a^2+2ab+b^2\ (a+b \\
 & \underline{a^2\qquad\qquad} \\
2a+b) & 2ab+b^2 \\
 & \underline{2ab+b^2} \\
 & *\quad *
\end{array}$$

Required the square root of $a^2+2ab+b^2+2ac+2bc+c^2$.

$$\begin{array}{rl}
 & a^2+2ab+b^2+2ac+2bc+c^2\ (a+b+c \\
 & \underline{a^2\qquad\qquad\qquad\qquad} \\
2a+b) & 2ab+b^2 \\
 & \underline{2ab+b^2} \\
2a+2b+c) & *\qquad * \quad 2ac+2bc+c^2 \\
 & \qquad\qquad\ \ \underline{2ac+2bc+c^2} \\
 & \qquad\qquad\quad *\quad *\quad *
\end{array}$$

Required the square root of $a^2-ax+\frac{x^2}{4}$

$$\begin{array}{rl}
 & a^2-ax+\frac{x^2}{4}\Big(a-\frac{x}{2} \\
2a-\frac{x}{2}\Big) & -ax+\frac{x^2}{4} \\
 & -ax+\frac{x^2}{4}
\end{array}$$

To extract any root of any compound quantity

Rule. Find the root of the leading term and place it in the quotient, and bring down the second term for a dividend. Involve the root last found to the power next below that whose root is to be found, and multiply it by the index of the given power for a divisor. Divide the dividend by the divisor for a new term in the root. Involve the whole root, and subtract and divide as before; proceed in this manner till the work is finished.

Example.

Required the square root of $a^4-2a^3b+3a^2b^2-2ab^3+b^4$.

$$\begin{array}{l} a^4-2a^3b+3a^2b^2-2ab^3+b^4(a^2-ab+b^2 \\ a^4 \\ \overline{2a^2)-2a^3b} \\ \quad \underline{a^4-2a^3b+a^2b^2=(a^2-ab)^2} \\ \qquad 2a^2)2a^2b^2 \\ \overline{a^4-2a^3b+3a^2b^2-2ab^3+b^4=(a^2-ab+b^2)^2} \end{array}$$

Therefore a^2-ab+b^2 is the root required.

PROPORTION.

The first relation of quantities is expressed by their arithmetical ratio: the second by their geometrical ratio. That term whose ratio is enquired into is called the antecedent; and that with which it is compared is called the consequent.

Then, of four quantities, the difference between the first and second is equal to the difference between the third and fourth, those quantities are called arithmetical proportionals; as the numbers 3, 7, 12, 16; and the quantities a, $a+b$, e, $e+b$. But quantities form a series in arithmetical proportion when they increase, or decrease by the same constant difference; as these, 1, 2, 3, 4; 10, 7, 4, 1; and a, $a+b$, $a+2b$, $a+3b$, $a+4b$, &c.

In four quantities arithmetically proportional, the sum of the extremes is equal to the sum of the mean terms; as in the arithmetical proportionals a, $a+b$, e, $e+b$, the sum of the extremes $a+e+b=$ to the sum of the mean terms $a+b+e$; therefore, to find the fourth arithmetical proportional, add the second and third quantities, and from the sum, substract the first term which will give the proportional sought.

If, of four quantities the quotient of the first and second be equal to that of the third and fourth, those quantities are then said to be in geometrical proportion; as 2, 6, 4, 12; and the quantities a, ax, b, bx, which are expressed after this manner.

$$\begin{array}{c} 2:6::4:12. \\ a:ax::b\cdot bx \end{array}$$

In four geometrical proportionals the product of the extremes is equal to the product of the middle terms; thus, $a+bx=ax+b$.

When a fourth proportional to any three given quantities is to be found, multiply the second by the third, and divide the product by the first, and the quotient will be the proportional required. Thus to find a fourth proportional to a, ar, and b; the process is $ar+b=arb$, and $arb\div a=br$ the proportional sought.

When a series of quantities increase by a common multiplicator, or decrease by a common divisor, they are said to be in geometrical proportion continued: as

$$a,\ ar,\ ar^2,\ \&c.\ \text{or}\ a,\frac{a}{r},\ \frac{a}{r^2},\ \&c.$$

The common multiplier or divisor, is called the common ratio.

In this kind of series the product of the first and fourth is equal to the product of the second and last but one, or to the product of any two terms equally remote from the extremes.

The sum of a series of geometrical proportionals wanting the first term, is equal to the sum of all but the last term multiplied by the common ratio.

EQUATIONS.

1. An equation is a proposition stating the quality of two quantities by placing the sign $=$ between them.

2. Equations containing only one unknown quantity and its powers, are divided into *orders* according to the highest power of the unknown quantity to be found in any of its terms.

$$\left.\begin{array}{l}\text{If the highest}\\ \text{power of the}\\ \text{unknown quantity in any term}\\ \text{be the}\end{array}\right\}\left\{\begin{array}{c}\text{1st,}\\ \text{2d,}\\ \text{3d,}\\ \text{\&c,}\end{array}\right\}\left\{\begin{array}{c}\text{the}\\ \text{equation is}\\ \text{called}\end{array}\right\}\left\{\begin{array}{c}\text{simple,}\\ \text{quadratic;}\\ \text{cubic,}\\ \text{\&c.}\end{array}\right.$$

But the exponents of the unknown quantities are supposed to be integers, and the equation to be cleared of fractions in which the unknown quantity or any of its powers enters the denominators, thus $x+a=\frac{3x-b}{c}$ is a simple equation; $3x-\frac{b}{2x}=12$, when cleared of the fraction by multiplying both sides by $2x$ is $6x^2-5=24x$ or a quadratic: $x^3-x^4=x^6-20$ which is an equation of the sixth order, &c.

To resolve an equation is to find the value of an unknown term, in those which are known.

Of simple equations and their resolutions.

Rule 1. Any quantity may be transposed from one side of an equation to the other by changing its sign.

Thus if $3x-10=2x+5$
Then $3x-2x=10+5$, or $x=15$.
And $5x+b=a+2x$

By transposing $3x=a-b$.

For equal quantities are here added to, or subtracted from, both sides.

Corollary. The signs of the terms of an equation may be changed to the contrary, and the equation still be true.

Rule 2. Any quantity by which the unknown quantity is multiplied may be taken away, by dividing all the other quantities of the equation by it thus

$$\text{If } ax=b$$
$$x=\frac{b}{a}.$$
$$\text{Also if } mx+nb-am$$
$$x+\frac{nb}{m}=a$$

For if equal quantities are divided by the same quantity, the quotients will be equal.

Rule 3. If the term of an equation be fractional, its denominator may be taken away by multiplying the other terms by it: thus

$$\text{If } \frac{x}{a}=b+c$$
$$x=ab+ac.$$
$$\text{And if } a-\frac{b}{a}=c$$
$$ax-b-cx;\ \text{and, by transposing,}$$
$$ax-cx=b;\ \text{and, by division, } x=\frac{b}{a-c}.$$

For by multiplying all the terms of the equation by the same quantity, the quantities on each side are equal.

Coroll. If any quantity on both sides of the equation have the same sign, it may be taken from both. And if all the terms in an equation are multiplied or divided by the same quantity, it may be taken away from all of them: *e.*

If $3x+a=a+b$, then $3x=b$.

If $2ax+3ab=ma+a^2$, then $2x+3b=m+a$.

If $\frac{x}{3}-\frac{4}{3}=\frac{16}{3}$, then $x-4=16$.

Hereby the unknown term may be separated from the known, and the equation is resolved.

Examples of simple equations solved by these rules.

$$\text{If } 3x+5=x+9$$
$$2x=4$$

$$\text{If } 5x-\frac{5x}{2}+12=\frac{4x}{3}+26$$
$$5x-\frac{5x}{2}-\frac{4x}{3}=26-12-14$$
$$30x-15x-8x=84$$
$$\text{or } 7x=84$$
$$x=\frac{84}{7}=12.$$

$$\text{If } \frac{5}{x}+\frac{9}{4}=16$$
$$\frac{20}{x}+9=64$$
$$20+x9=64$$
$$20=64x-9x=55x$$
$$20 \quad 4$$

Solution of questions producing simple equations.

General Rule. Express the unknown quantities by letters, and the relations between the known and unknown, or, as they are called, the conditions, by equations, which being resolved, give the answer.

Example. If the question is concerning two numbers, they may be called x and y, and the conditions from which they are to be investigated must be expressed by equations: thus

If it be required that the sum of two numbers sought be 60, that condition is thus expressed } $x+y=60$.

If their difference must be 24 then $x-y=24$.

If their product is to be 96 then $xy=96$

If their quotient is to be 6, then $\frac{x}{y}=6$.

Case 1. When only one unknown quantity is to be found.

Rule. An equation involving the unknown quantity must be deduced from the question; and when there is but one unknown quantity, there can be but one independent equation in the question.

Ex. 1. To find a number to which if there be added a half, a third, and a fourth of itself, the sum will be 50.

Represent the unknown quantity by z, then half of it is $\frac{z}{2}$, a third $\frac{z}{3}$, &c. Therefore,

$$z+\frac{z}{2}+\frac{z}{3}+\frac{z}{4}=50.$$
$$24z+12z+8z+6z=1200$$
$$50z=1200$$
$$z=24$$

Ex. 2. A and B began to trade with equal stocks: A gained 200*l.* and B lost 100*l.* after which, A's stock was to B's as three to two. What did each begin with?

Let x = pounds each began with; then $x+200$ = A's stock increased by 200, and $x-100$ = B's diminished by 100. Now $x+200 : x-100 :: 3 : 2$. Then $2x+400=3x-300$ by mult. extremes and means. And $400=x-300$ by transposing $2x$: also $700=x$ by transp. -300. Therefore each began with 700*l.*

Case 2. When there are two unknown quantities.

Rule. Two independent equations involving the two unknown quantities, must be derived from the question. A value of one of the quantities must be derived from each of the equations; and the two values being put equal to each other, a new equation will be formed, involving only one unknown quantity.

Ex. A says to B, seven years ago I was three times as old as you were, and seven years hence I shall be twice as old as you will be. What are their present ages?

Let the ages of A and B be x and y, then seven years ago their ages were $x-7$ and $y-7$, and seven years hence they will be $x+y$ and $y+7$:

therefore, $x-7=3\times\overline{y-7}=3y-21$

$$x+7=2\times\overline{y+7}=2y+14$$
$$x=3y-14$$
$$x=2y+7$$
$$3y-14=2y+7$$
$$y=21\text{, the age of B}$$
$$x=49\text{, the age of A}$$

Case 3. When there are three or more unknown quantities.

Rule. In this case there must be three independent equations arising from the question, from each of which a value of one of the unknown quantities must be obtained: then by comparing these three values, two equations will arise involving only two unknown quantities. In like manner the rule may be extended to four or more unknown quantities.

Ex. To find three numbers, so that the first with half the other two, the second with one third of the other two, and the third with one-fourth of the other two, may each be equal to 34.

Let the numbers be x, y, z, and the equations are,

$$x+\frac{y+z}{2}=34$$
$$y+\frac{x+z}{3}=34$$

$z+\frac{x+y}{4}=34$; then by the first equation

$x=\frac{68-y-z}{2}$; and by the second

$x=102-3y-2$; and by the third

$x=136-4z-y$; therefore

$$\frac{68-y-z}{2}=102-3y-z$$

$y=\frac{136-z}{5}$; and by the two latter equations

$y=\frac{3z-34}{}$ therefore

$$3z-34 \quad 136-z$$

$$15z-170=272-2z$$
$$17z=442 \text{ or } z=26$$
$$y=22\text{, and } x=10.$$

General Solution of Problems.

In the solutions of the preceding questions

the given quantities, being numbers, disappear in the last conclusion, so that no general rules for like cases can be deduced from them But if letters are used to denote both the known and unknown quantities, a general solution may be obtained, because, during the whole operation, they retain their original form; whence the connection of the quantities will plainly discover the limits of the data, which is necessary to the perfect solution of a problem.

Ex. To find two numbers, of which the sum and difference are given.

Let s be the sum given, and d the difference; and let x and y be the numbers sought. Then

$$x+y=s$$
$$x-y=d$$
$$\text{Whence}\begin{cases}x=s-y\\x=d+y\end{cases}$$
$$d+y=s-y$$
$$2y=s-d$$
$$y=\frac{s-d}{2}$$
$$\text{And } x=\frac{s+d}{2}.$$

Equations are either pure or adfected.

Of Pure Equations.

A pure equation is that in which only one power of the unknown quantity is found.

Rule. Make the power of the unknown quantity stand alone, then extract the root of the same denomination out of both sides, and this will give the value of the unknown quantity.

Example.

$$\text{If } a^2+ax^2=b^3$$
$$ax^2=b^3-a^2$$
$$x^2=\frac{b^3-a^2}{a}$$
$$x=\sqrt{b^3-a^2}$$

Of Adfected Quadratic Equations.

An adfected equation is that in which different p[illegible] of the unknown quantity fou[illegible] the several terms. An adfected quadratic equation (commonly called a quadratic) involves both the unknown quantity and its square.

Rule. 1. Transpose the terms involving the unknown quantity to one side, and the known terms to the other; so that the term containing the square may be positive.

2. If the square of the unknown quantity be multiplied by any coefficient, divide all the terms of the equation by it, so that the coefficient of the square of the unknown quantity may be 1.

3. Add to both sides the square of half the [illegible]fficient of the unknown quantity, and the side of the equation involving the unknown quantity will be a complete square.

4. Extract the square root from both sides of the equation, and by transposing the half-coefficient just mentioned, a value of the unknown quantity will be had in known terms. The different forms of quadratic equations expressed in general terms, being reduced by the first and second parts of the rule are these

1. $x^2+ax=b^2$
2. $x^2-ax=b^2$
3. $x^2-ax=-b^2$.

Case 1. $x^2+ax=b^2$

$$x^2+ax+\frac{a^2}{4}=b^2+\frac{a^2}{4}$$
$$x+\frac{a}{2}=\pm\sqrt{b^2+\frac{a^2}{4}}$$
$$\sqrt{b^2+\frac{a^2}{4}}-\frac{a}{2}.$$

Case 2. $x^2-ax=b^2$

$$x^2-ax+\frac{a^2}{4}=b^2+\frac{a^2}{4}$$
$$x-\frac{a}{2}=\pm\sqrt{b^2+\frac{a^2}{4}}$$
$$x=\frac{a}{2}\pm\sqrt{b^2+\frac{a^2}{4}}$$

Case 3. $x^2-ax=-b^2$

$$x^2-a^2+\frac{a^2}{4}=\frac{a^2}{4}-b^2$$
$$x-\frac{a}{2}=\pm\sqrt{\frac{a^2}{4}-b^2}$$
$$x=\frac{a}{2}\pm\sqrt{\frac{a^2}{4}-b^2}.$$

1. Every quadratic equation will have two roots, except those of the third form, whose roots become impossible. 2. In the two first forms, one of the roots must be positive, and the other negative. 3. In the third form, if $\frac{a^2}{4}$ or the square of half of the coefficient of the unknown quantity be greater than b^2, the known quantity, the two roots will be positive If $\frac{a^2}{4}$ be equal to b^2, the two roots become equal; but if $\frac{a^2}{4}$ is less than b^2, the quantity under the radical sign will be negative, and the two roots are impossible. 4. If the equation express the relation of magnitudes abstractedly, where a contrariety cannot be supposed to take place, there are no negative roots.

Solution of questions producing quadratic Equations.

The operation till we arrive at a quadratic equation, is the same as in the solution of simple equations.

Examples. One lays out a certain sum in goods, which he sells again for 24*l.* and gains as much per cent. as the goods cost him. What was the cost?

If the money laid out be 1 | y

The gain will be 2 $24-y$

But this gain is $y:\ 24-y::100$ 3 $\frac{2400-100y}{y}$ per cent

Therefore by question $y=\frac{2400-100y}{y}$

And by mult. & trans. $y^2+100y=2400$

Completing the sqr. $y^2+100y+50^2=2400+2500=4900$

Extract the root $y+50=\pm\sqrt{4900}=70$

Transpose $y=\pm70-50=20$ or -120

The answer is 20*l.* the other root -120 being negative, is impossible.

Of indeterminate Problems.

If there are more unknown quantities in a question than equations, by which their relations are expressed, it is indetermined.

Example. To divide a given square number into two parts, each of which shall be a square number.

Here are two quantities sought, and only one equation expressing their relation; but it is also required that they may be rational, which cannot be expressed by an equation; therefore another condition must be assumed so as to obtain a solution in rational numbers.

Let the given square be a^2; let one of the squares sought be x^2, the other is a^2-x^2. Let $rx-a$ also be a side of the last square, therefore

$$r^2x^2-2rxa+a^2=a^2-x^2$$

By transp. $r^2x^2+x^2=2rxa$

Divide by x $r^2x+x=2ra$

Therefore $=\frac{2ra}{r^2+1}$

And $rx-a=\frac{2r^2a}{r^2+1}-=\frac{r^2-1}{r^2+1}a.$

Let r therefore be assumed at pleasure, and $\frac{2ra}{r^2+1}$, $\frac{r^2-1}{r^2+1}a$, which must always be rational, will be the sides of the two squares required.

Thus, if $a^2=100$; then, if $r=3$, the sides of the two squares are 6 and 8, for $36+64=100$.

Also, let $a^2=64$. Then, if $r=2$, the sides of the squares are $\frac{32}{5}$ and $\frac{24}{5}$; and $\frac{1024}{25}+\frac{576}{25}=\frac{1600}{25}=64$.

The reason of the assumption of $rx-a$ as a side of the square a^2-x^2, is, that being squared and put equal to this last, the equation manifestly will be simple, and the root of such an equation is always rational.

Of the origin and composition of Equations, and of the Signs and Coefficients of their Terms.

The higher order of equations and their general affections, are best investigated by considering their origin from the combination of inferior equations. Now all the terms of any equation are brought to one side, and the equation is expressed by making them equal to 0. Therefore if a root of the equation be inserted instead of the unknown quantity, the positive terms will be equal to the negative, and the whole equal to 0.

Def. When an equation is put into this form, the term in which the unknown quantity (x) is of the highest power, made the first, that in which the index of x is less by 1, the second, and so on till the last into which the unknown quantity does not enter, and which is called the absolute term.

Prop. I. If any number of equations be multiplied together, an equation will be produced of which the dimension is equal to the sum of the dimensions of the equations multiplied. If any number of simple equations be multiplied together as $x-a=0$, $x-b=0$, $x-c=0$, &c. the product will be an equation of a dimension containing as many units as there are simple equations. So if higher equations are multiplied together one of a higher order will be produced. *Conversely.* An equation of any dimension is considered as compounded of simple equations or of others the sum of whose dimensions is equal to that of the given one. By the resolution of equations these inferior equations are discovered, and by investigating the component simple equations, the roots of the higher orders are found.

Cor. 1. An equation admits of as many solutions, or has as many roots, as there are simple equations in it.

Cor. 2. Conversely, no equation can have more roots than dimensions.

Cor. 3. Imaginary or impossible roots must enter an equation by pairs, because they arise from quadratics. And an equation of an even dimension may have all its roots, or an even number of them impossible; but an equation of an odd dimension, must have one positive root at least.

Cor. 4. The roots are positive or negative according to the roots of the simple equations.

Cor. 5. When one root of an equation is discovered, one of the simple equations is found; and the given equation being divided by it, will give an equation of a dimension lower by 1.

Prop. II. To explain the general properties of the signs and coefficients of the terms of an equation.

Let $x-a=0$, $x-b=0$, $x-c=0$, the roots are any positive quantities $+a$, $+b$, $+c$, $+d$, &c. And let $x+m=0$, $x+n=0$, &c. be simple equations, whose roots are any negative quantities $-m$, $-n$, and let any number of these equations be multiplied together as in the following table:

$$x-a=0$$

$$\times \quad x-b=0$$

$$\left.\begin{matrix}x^2-ax\\-bx+ab\end{matrix}\right\}=0 \text{ a quadratic.}$$

$$\times\ x-c=0$$

$$=x^3\left.\begin{matrix}-a\\-b\\-c\end{matrix}\right\}\times x^2\ \left.\begin{matrix}+ab\\+ac\\+bc\end{matrix}\right\}\times x-abc=0 \text{ a cubic.}$$

$$\times\ x-m=0$$

$$=x^4\left.\begin{matrix}-a\\b\\-c\\+m\end{matrix}\right\}\times x^3\left.\begin{matrix}+ab\\+ac\\+bc\\-am\\-bm\\-cm\end{matrix}\right\}\times x^2\left.\begin{matrix}-abc\\+abm\\+acm\\+bcm\end{matrix}\right\}\times -abcm=0, \text{ a biquadratic, \&c.}$$

From this it appears: 1. That in a complete equation the terms are always greater by a unit than the dimension of the equation.

2. The coefficient of the first term is 1. The coefficient of the second term is the sum of the roots with their signs changed. The coefficient of the third term is the sum of all the products made by multiplying any two of the roots together. The coefficient of the fourth term is the sum of all the products that can be made by multiplying together any three of the roots with their signs changed.

The last term is the product of all the roots, with their signs changed.

3. From induction it appears that in any equation there are as many positive roots as there are changes in the signs of the terms, and the remaining roots are negative.

Cor. If a term of an equation be wanting, the positive parts of its coefficient are equal. If there is no absolute term, some of the roots $=0$, and the equation may be depressed by dividing all the terms by the lowest power of the unknown quantity in any of them.

Of the Transformation of Equations.

Prop. I. The affirmative roots of an equation become negative, and the contrary by changing the signs of the alternate terms, beginning with the second.

Thus the roots of the equation $x^4-x^3-19x^2-49x-30=0$, are $+1,+2,+3,-5$, but the roots of the equation $x^4+x^3-19x^2-19x-49=-300$, are $-1,-2,-3,+5$.

Prop. II. An equation may be transformed into another having its roots greater or less than the roots of the given equation by a given difference.

Let e be the given difference; then $y=x\pm e$, and $x=y\pm e$; and if for x and its powers in the given equation $y\pm e$ and its powers be inserted, a new equation will arise, in which the unknown quantity is y, and its value will be $x\pm e$.

Let the equation proposed be $x^3-px^2+qx-r=0$, of which the roots must be diminished by e. By inserting for x and its powers $y+e$ and its powers, the equation required is

$$\left.\begin{array}{llll} y^3 & +3ey^2 & +3ey^2 & +e^3 \\ & -py^2 & -2pey & -pe^2 \\ & & +qy & +qe \\ & & & -r \end{array}\right\}=0.$$

Cor. 1. The use of this transformation is to take away the second, or any other intermediate term; for as the coefficients of all the terms of the transformed equation, except the first, involve the powers of e, and known quantities only, by putting the coefficient of any term equal to 0, and resolving that equation, a value of e may be determined, which being substituted, will make that term to vanish.

Cor. 2. The second term may be taken away by the solution of a simple equation, the third by a quadratic, and so on.

Prop. III. An equation may be transformed into any other, whose roots shall be equal to the roots of the given equation multiplied or divided by a given quantity

Ex. Let $y=xe$, or $y=\frac{x}{e}$

Then substitute for x and its powers $\frac{y}{e}$ or ye and its powers, and the new equation will have the property required.

Cor. 1. An equation in which the coefficient of the first term is any unknown quantity, as a, may thus be transformed into another, in which the coefficient of the first term will disappear. Thus let the equation be $ax^3-p^2+9x-r=0$

Suppose $y=ax$, or $x+\frac{y}{a}$ and for x and its powers insert $\frac{y}{a}$ and its powers, and the equation becomes $\frac{y^3}{a^2}-\frac{py^2}{a^2}+\frac{qy}{a}-r=0$, or $y^3-py^2+qay-a^2r=0$.

Cor. 2. Fractions may be taken away from an equation by multiplying the equation by the denominators, and by this proposition the equation may be then transformed into another without fractions, in which the coefficient of the first term is 1.

Cor. 3. And hence if the coefficient of the second term of a cubic equation be not divisible by 3, the fractions thence arising, wanting the second term, may be taken away by the preceding corollary. But the second term may be also taken away, so that there shall be no such fractions in the transformed equation by supposing $x=\frac{z\pm p}{3}$, $\pm p$ being the coefficient of the second term. And if the equation $ax^3-bx^2+qx-r=0$ be given which p is not divisible by 3, by supposing $x=\frac{z+p}{3a}$ the transformed equation reduced is $z^3-\overline{3p^2+9aq}\times z-zp^3+9apq-7a^2r=0$, wanting the second term, having 1 for the coefficient of the term, and the coefficients of the others all integers,

General Corollary to the preceding Propositions.

If the roots of these transformed equations be found by any method, the roots of the original equation will be found from the simple equations expressing their relation.

These principles and operations will supply rules for resolving equations of all orders; and the student who is desirous of more particular information may consult the excellent elementary treatise of the Rev. B. Bridge of Cambridge, Bonnycastle's Algebra, and a recent work by Mr. Peter Nicholson, with others.

ALGOL, a fixed star of the second magnitude in the constellation of Perseus, otherwise called Medusa's head. This star has been subject to singular variations, appearing at different times of different magnitudes, from the fourth to the second, which is its usual magnitude.

ALGORITHM an Arabic word frequently used to denote the practical rules of Algebra, and sometimes also the practice of common arithmetic, in which sense it coincides with with *logistica numeralis*, or the art of numbering truly and readily.

ALIEN, in law, is a person born in a foreign country, not within the king's allegiance, in contradistinction from a denizen or natural subject.

An alien is incapable of inheriting lands in England, till naturalized by an act of parliament. No alien is entitled to vote in the choice of members of parliament, has a right to enjoy offices, or can be returned on any jury, unless where an alien is party in a cause; and then the inquest of jurors shall be one half natives and the other aliens.

ALLIMENTARY *duct*, a name by which some call the intestines on account of the food's passing through them. See ANATOMY.

ALIMONY, *alimonia*, in law, denotes the maintenance sued for by a wife, in case of a separation from her husband, wherein she is neither chargeable with elopement nor adultery

ALIQUANT *parts*, in arithmetic, the which will not divide or measure the whole number exactly. Thus, 7 is an aliquant part

of 16, for twice 7 wants 2 of 16, and three times 7 exceeds 16 by 5.

ALIQUOT *part*, is such part of a number as will divide and measure it exactly, without any remainder. For instance, 2 is an aliquot part of 4, 3 of 9, and 4 of 16.

Aliquot parts must not be confounded with commensurable ones; for though the former be all commensurable, yet these are not always aliquot parts: thus 4 is commensurable with 6, but is not an aliquot part of it.

ALISMA, in botany, the *water plantain*, a genus of plants of the class and order hexandria polyginia. The essential characters are calyx three-leaved; petals three; seeds several. There are nine species, most of which are to be found in England; they are inhabitants of watery places, bogs, &c.

ALKAHEST. The pretended universal solvent, or menstruum of the ancient chemists. Kunckel has very well shown the absurdity of searching for a universal solvent, by asking, "If it dissolve all substances, in what vessels can it be contained?"

ALKALESCENT. Any substance in which alkaline properties are beginning to be developed, or to predominate, is termed alkalescent. The only alkali usually observed to be produced by spontaneous decomposition is the volatile: and from their tendency to produce this, some species of vegetables, particularly the cruciform, are styled alkalescent, as are some animal substances.

ALKALI. A term derived from kali the Arabic name of a plant, from the ashes of which one species of alkaline substance can be extracted. Alkalis may be defined, those bodies which combine with acids, so as to neutralize or impair their activity, and produce salts. Acidity and alkalinity are therefore two correlative terms of one species of combination.

The alkalis may be arranged into three classes: 1*st*, Those which consist of a metallic basis combined with oxygen. These are three in number, potash, soda, and lithia. 2*d*, That which contains no oxygen, viz. ammonia. 3*d*, Those containing oxygen, hydrogen, and carbon.

Besides neutralizing acidity, and thereby giving birth to salts, the first four alkalis have the following properties.—

1st, They change the purple colour of any vegetables to a green, the reds to a purple, and the yellows to a brown. If the purple have been reddened by acid, alkalis restore the purple.

2d. They possess this power on vegetable colours *after* being saturated with carbonic acid, by which criterion they are distinguishable from the alkaline earths.

3d, They have an acrid and urinous taste.

4th, They are powerful solvents or corrosives of animal matter; with which, as well as with oils in general, they combine, so as to produce neutrality.

5th, They are decomposed, or volatilized, at a strong red heat.

6th, They combine with water in every proportion, and also largely with alcohol.

7th, They continue to be soluble in water when neutralized with carbonic acid; while the alkaline earths thus become insoluble.

ALKALIMETER. The name first giv by M. Descroizilles to an instrument for determining the quantity of alkali in the potash of commerce; an instrument on a much more simple principle has recently been invented by Dr. Ure, and is now in general use.

ALLAMANDA, in botany, a genus of the pentandria monogynia class and order: corolla twisted; capsule lens-form, erect, echinate, one-celled, two-valved, many-seeded. One species, viz. cathartica, a climbing plant, found in Guiana. The infusion of its leaves is used in the cholic.

ALLEGIANCE, is the lawful duty from the subject to the sovereign; and is either natural, as every subject born ought to pay; acquired; where a man is naturalized; local, which a man ought to pay who comes under the dominion of the king.

ALLEGORY, in matters of literature, a mode or species of writing, wherein something else is signified than the words in their literal meaning express. An allegory may be considered as a series or chain of metaphors, continued through a whole discourse. For example, when the prophets represent the Jews under the allegory of a vine planted, cultivated and watered by the hand of God which instead producing good fruit, brings forth verjuice and sour grapes.

ALLEGRO, in music, an Italian word denoting that the part is to be played in a sprightly, brisk, lively, and gay manner.

ALLEMAND, a sort of grave solemn music, with good measure and a slow movement. It is also a kind of dance very common in Germany and Switzerland.

ALLIGATION, in arithmetic, is the rule of mixture, which teaches to compound veral species of ingredients or commodities together, according to any intent or design proposed, and is either medical or alternate.

Alligation *medical* shews the rate or price of any mixtures, when the several quantities of the mixture, and their rates, are known.

Alligation *alternate* teaches to mix goods, of different prices, in such proportion, that the mixture may be sold for any price proposed.

ALLITERATION, in rhetoric, is a figure or decoration in language, chiefly used in poetry, and consisting in the repetition of the same letter or letters at certain intervals, whence the name is derived.

ALLIONIA, a genus of plants of the class and order *tetrandria monogynia*. The corolla is one-petalled and funnel shaped; and the essential character is calyx, common, oblong, simple, three-flowered; proper obsolete, superior, corolla irregular; receptacle naked. There are two species, natives of South America.

ALLIUM, Garlick, in botany, a genus of plants, of the hexandria monogynia class and order. The corolla is six-petalled, and the essential character is, cor. six-parted, spreading, spathe many flowered: umbel heaped caps. superior.

This is a very extensive genus of plants, comprehending the A. *porrum* or *leek*: the A. *cepa* or onion, with all their varieties. There are in all 43 species.

ALLODIAL, an epithet given to an inheritance held without any acknowledgement to a lord or superior, in opposition to feudal.

Allodial lands are free lands, for which neither fees, rents, nor services are due.

ALLOY, or **Allay**, a proportion of a baser metal mixed with a finer one. Thus, all gold coin has an alloy of silver and copper, as silver coin has of copper alone; the proportion in the former case, for standard gold, being two carats of alloy in a pound troy of gold; and in the latter 18 pennyweights of alloy for a pound troy of silver.

According as gold or silver has more or less alloy than that mentioned above, it is said to be coarser or finer than the standard. However, it ought to be remarked, that the coin of different nations varies greatly in this respect; some using a larger, and others a less proportion of alloy, the original intention of which was to give the coin a due degree of hardness.

ALLUSION, in rhetoric, a figure by which something is applied to, or understood of another, on account of some similitude between them.

ALLUVIAL *Formations*, in geology, are recent deposits in valleys or in plains, of the *detritus* of the neighbouring mountains. Gravel, loam, clay, sand, brown coal, wood coal, bog iron ore, and calc tuff, compose the alluvial deposits. The gravel and sand sometimes contain gold and tin, if the ores exist in the adjoining mountains. Petrified wood and animal skeletons are found in the alluvial clays and sand.

ALMAGEST, the name of a celebrated book composed by Ptolemy; being a collection of a great number of the observations and problems, of the ancients, relating to geometry and astronomy; but especially the latter. And being the first work of this kind which has come down to us, and containing a catalogue of the fixed stars, with their places, besides numerous records and observations of eclipses, and the motions of the planets.

ALMANAC, a table containing the calendar of days and months, the rising and setting of the sun, the age of the moon, &c. The *Nautical and Astronomical Almanac* is a kind of national almanac, being published under the direction of the commissioners of longitude. This work, in addition to the matter which it contains in common with other almanacs, furnishes the mariner with all the astronomical information connected with navigation.

ALMOND *tree*, in botany, see **Amygdalus**.

ALMUCANTURS, in astronomy, an Arabic word denoting circles of the sphere passing through the centre of the sun, or a star, parallel to the horizon, and are the same as parallels of altitude. They serve to shew the height of the heavenly bodies, and are generally inscribed on quadrants, &c.

ALOES. This is a bitter juice, extracted from the leaves of a plant of the same name. Three sorts of aloes are distinguished in the shops by the names of aloe soccotrina, aloe hepatica, and aloe caballina. The first denomination, which is applied to the purest kind, is taken from the island of Zocotora; the second, or next in quality, is called hepatica, from its liver colour; and the third, caballina, from the use of this species being confined to horses. These kinds of aloes are said to differ only in purity, though, from the difference of their flavours, it is probable that they may be obtained, in some instances, from different species of the same plant. It is certain however, that the different kinds are all prepared at Morviedro, in Spain, from the same leaves of the common aloe.

ALPHABET. *In literature, alphabet signifies the natural or accustomed series of the several letters of a language. The word is derived from* alpha *and* beta, the first two letters in the Greek alphabet. Alphabets of different nations vary in the number of their constituent letters. The English alphabet contains 24 letters, to which if *j* and *v*, consonants, are added, the sum will be 26; the French 23; the Hebrew, Chaldee, Syriac, and Samaritan, 22 each; the Arabic 28; the Persian 31; the Turkish 33; the Georgian 36; the Coptic 32; the Muscovite 43; the Greek 24; the Latin 22; the Sclavonic 27; the Dutch 26; the Spanish 27; the Italian 20; the Ethiopic, as well as Tartarian, 202; the Indian of Bengal 21; the Baramos 19; the Chinese, properly speaking, have no alphabet, except we call their whole language their alphabet; their letters are words, or rather hieroglyphics, and amount to about 80,000.

ALPINIA, a genus of the monandria monogynia class and order. The corolla is monopetalous and tubulose; and the essential character is, calyx three-toothed, equal, tubulose; corolla three-parted, equal; nect. two-lipped, the lower lip spreading.

It derives its name from Prosper Alpinus, a celebrated botanist. There is but one species, a native of the West Indies.

ALSTONIA, a genus of the polyandria monogynia class and order. The corolla is shorter than the calyx; and the essential character is, corrolla one-petalled, eight or ten cleft; the clefts alternated. There is only one species, a shrub of South America, the leaves of which are said to have the taste of tea.

ALSTROEMERIA, in botany, a genus of the hexandria monogynia class and order: corolla six-petalled, somewhat two-lipped; the lower petals tubular at the base; stamina declined. There are six species, all found in South America.

ALT, in music, a term applied to that part of the great scale of sounds which lies between F above the treble-cleft note and G in altissimo.

ALTAR, a place upon which sacrifices were anciently offered to some deity.

The heathens at first made their altars only of turf: in following times they were made of stone, of marble, of wood, and even of horn, as that of Apollo in Delos. Altars differed in figure as well as in materials. Some were round, others square, and some oval. They always fronted east, and were adorned with sculpture, inscriptions, and the leaves and flowers of particular trees sacred to the deity to whom they were raised.

ALTERN *base*, in trigonometry, a term used in contradistinction to the true base. Thus in oblique triangles, the true base is either the sum of the sides, and then the difference of the sides is the altern base; or the true base is the difference of the sides, and then the sum is the altern base.

ALTERNATE, in heraldry, a term used respect to the situation of the quarters. Thus the first and fourth quarters, and the second and third being generally the same, are called alternate quarters *Alternate*, in botany

means that disposition of the leaves of a plant when the first on one side of a branch is higher than the first on the other side, and so on with the rest.

ALTERNATION is used for the different ways which any number of quantities may be changed, or combined. See COMBINATION.

ALTHÆA, MARSH-MALLOW, a genus of plants, with a double calyx, the exterior one being divided into nine segments; the fruit consists of numerous capsules, each containing a single seed. It belongs to the monadelphia polyandria class of Linnæus. The essential character is, calyx double, outer nine-cleft; arils many, one-seeded.

There are seven species, of which the A. officinalis, or common marsh mallow, is well known.

ALTIMETRY, denotes the art of measuring altitudes or heights. See MENSURATION.

ALTITUDE, in geometry, one of the three dimensions of body; being the same with what is otherwise called height.

Altitude of a figure is the distance of its vertex from its base, or the length of a perpendicular let fall from the vertex to the base.

ALTITUDE, in optics, is the height of an object above a line drawn parallel to the horizon from the eye of the observer.

ALTITUDE *of the eye*, in perspective, is its perpendicular height above the geometrical plane.

ALTITUDE *of a star, &c.* in astronomy, is an arch of a verticle circle, intercepted between the stars and the horizon.

This altitude is either true or apparent, according as it is reckoned from the rational or sensible horizon, and the difference between these is what is called by astronomers the parallax of altitude. Sailors generally take the altitude of the sun and stars with a quadrant, but this method is liable to an error, arising from the ship's motion. M. Parent has given a method of taking altitudes by means of a common watch, which is liable to a much less error than that of the quadrant. His method is this: having observed the difference of time between the rising of two stars, the right ascension and declination of which are known from astronomical tables, in the Nautical Almanac, it will be easy to distinguish that part of the difference which arises from that different position, from that arising from the obliquity of the sphere. Now this last is precisely the altitude of the pole of the place of observation; for as to the way the ship may have made between the rising of the two stars, it is so small as to be safely overlooked, or at most estimated in the common way of reckoning.

ALUM, is one of those substances which chemists distinguish by the name of triple salts. It is composed of sulphuric acid, potash, alumina, and water. Alum is of a white colour; it has an astringent and acid taste, and crystalizes in regular octahedrons. From the experiments of several eminent chemists, its specific gravity appears to be 1.731. Water at the temperature of 60 dissolves about one fifteenth of its weight of alum; but boiling water dissolves about three fourths of its weight. When alum is exposed to a dry atmosphere, a slight efflorescence takes place; when heated it speedily becomes liquid. Alum is much used by dyers and others artists in their different processes. The principal alum manufactory in Britain is at Hurlett, near Paisley, on the estate of the earl of Glasgow. The next in magnitude is at Whitby.

ALUMINA. One of the primitive earths, which, as constituting the plastic principle of all clays, loams, and boles, was called argil or the argillaceous earth, but now, as being obtained in greatest purity from alum, is styled alumina. It was deemed elementary matter till Sir H. Davy's celebrated electro-chemical researches led to the belief of its being, like barytes and lime, a metallic oxide. Alumina is widely diffused in nature. It is a constituent of every soil, and of almost every rock. It is the basis of porcelain, pottery, bricks, and crucibles. Its affinity for vegetable colouring matter is made use of in the preparation of lakes, and in the arts of dyeing and calico printing. Native combinations of alumina, constitute the fuller's earth, ochers, boles, pipeclays, &c.

ALURNUS, a genus of insects of the order of cleoptera, with filiform antennæ, six short feelers and a horny arched jaw. There are three species, natives of the Cape of Good Hope, viz. the A. grossus, femoratus, and dentipes.

AMALGAM, a mass of mercury united and incorporated with some other metal.

Amalgams grow soft with heat and hard with cold; and the metals amalgamated with mercury, assume a consistence harder or softer, in proportion to the quantity of mercury employed in the amalgam.

Amalgams are used either to render a metal fit to be extended on some works, as in gilding; or else to reduce the metal into a very subtile powder.

For the composition of amalgam for electrical machines see ELECTRICITY.

AMALGAMATION, in chemistry, the operation of making an amalgam, or of mixing quicksilver with some metal, is performed by fusing, or at least igniting the metal, and in this state adding a proportion of mercury to it; upon which they mutually attract and incorporate with each other.

Of all metals, gold unites with mercury with the greatest facility; next to that, silver; then lead, tin, and every metal, except iron and copper, the last of which incorporates with quicksilver with great difficulty, and the former scarcely at all. An amalgam of tin and mercury is used for looking-glasses. In this case, the glass-plate is laid on an even board, on which is spread very evenly some tin-foil, and on the tin-foil is spread quicksilver: the glass is then laid on the quicksilver, and a number of leaden weights, covered with baize or flannel, are laid upon the glass; in this state it remains several days, till the tin and quicksilver, in the state of amalgam, adhere firmly to the glass, by means of which it acquires the power of reflection.

AMARANTHUS, in botany, the name of a genus of plants, sometimes called prince's feather, the flower of which is rosaceous, and its fruit an oval or roundish capsule, containing only one large seed of a roundish compressed shape. The characters are: the male calyx is a five or three-leafed perianthium, erect, coloured, and persistent: there is no corolla: the stamina consists of five or three erect capillary

filaments, the length of the calyx; the antheræ are oblong and versatile: the female calyx the same as the male, and no corolla: the pistillum has an ovate germen; the styli are three, short and subulated; the stigmata simple and persistent: the pericarpium is an ovate capsule, three-beaked, unilocular, and cut round: the seed is one, globular, compressed, and large. Of this there are 29 species; the most remarkable of which are: the A. bicolor, melancholicus, or two-coloured amaranthus; A. maximus, or tree-like amaranthus; A. oleraceus, used by the Indians as a substitute for cabbage; A. tricolor or three-coloured amaranthus, which is cultivated in our gardens. The amaranthus are all annuals.

AMARILLIS, a genus of the hexandria monogynia class and order, of the natural order of lilia, which in its flower it resembles. The essential character is, corolla hexapetaloid, irregular; filaments inserted into the throat of the tube, bending down, unequal in proportion or direction. There are 29 species, all of them highly ornamental, but only one, the A. lutea, perfectly hardy in this country. The A. regina, the vittata, the jacobea, belladonna, and Guernsey lily, are well known in the stoves and green-houses of the curious in plants. To describe them is impossible, but no flowers are more beautiful.

AMASONIA, in botany, a genus of the didynamia angiospermia class and order: calyx five-cleft: corolla tubular, with a small five-cleft border: berry four-seeded. There are two species.

AMATEUR, in the arts, denotes a person understanding, loving, or practising the fine arts, without any regard to pecuniary advantage.

AMBASSADOR, a person appointed by one sovereign power to another, to superintend his affairs at some foreign court, and supposed to represent the power from which he is sent. The person of an ambassador is inviolable.

AMBER, is a hard, brittle, tasteless substance; sometimes transparent, but mostly semi-transparent or opaque, and of a glossy surface. It is found of nearly all colours, but chiefly yellow or orange, and often contains leaves, and sometimes insects. Amber, is capable of a fine polish, and becomes electric by friction. When rubbed or heated it emits a peculiar, but agreeable smell. Its specific gravity is from 1.065 to 1.100.

In the second volume of the Edinburgh Philosophical Journal, Dr. Brewster has given an account of some optical properties of amber, from which he considers it established beyond a doubt that amber is an *indurated vegetable juice*; and that the traces of a regular structure, indicated by its action upon polarized light, are not the effect of the ordinary laws of crystalization by which *mellite* has been formed, but are produced by the same causes which influence the mechanical condition of gum Arabic, and other gums, which are known to be formed by the successive deposition and induration of vegetable fluids.

AMBERGRIS, is a substance found floating in the sea near the coasts of various tropical countries. Different opinions formerly prevailed as to the origin of this substance; but it is now allowed to be a concretion formed in the stomach of the *physeter macrocephalus*, or spermaceti whale. Its colour is ash-grey, with brownish yellow and white streaks. It has an agreeable smell, which improves by keeping. Its price being in London so high as a guinea per oz., leads to many adulterations. Genuine ambergris is readily known by the richness of its fragrance when a hot needle is thrust into it.

AMBIDEXTER, a person who can use both hands with the same facility, and for the same purposes, that the generality of people do their right hands.

Were it not for education, some think that all mankind would be ambidexters; and, in fact, we frequently find nurses obliged to be at a good deal of pains before they can bring children to forego the use of their left hands. It is to be regretted, that any of the gifts of nature should be thus rendered in a great measure useless, as there are many occasions in life which require the equal use of both hands: such are the operations of bleeding in the left arm, left ancle, &c.

AMBROSIA, in botany, the name of a distinct genus of plants, with flosculous flowers, composed of several small infundibuliform floscules, divided into five segments: these, however, are barren; the fruit, which in some measure resembles a club, growing on other parts of the plant.

This genus belongs to the monoecia pentandria class and order. There are five species.

AMBROSINIA, in botany, a genus of the monoecia monadelphia class and order; of which there is a species, found in the island of Sicily: spathe one-leafed, separated by a membranaceous partition, containing the stamina in the hinder cell and upper part of the partition, pistils in the outer cell.

AMBRY, a place in which are deposited all utensils necessary for house-keeping.

In the ancient abbeys and priories, there was an office under this denomination, wherein were laid up all charities for the poor.

AMBULIA, a genus of the didynamia angiospermia class and order. It grows in Malabar, has an aromatic smell, and is administered in cases of fever in the form of a decoction.

AMBUSCADE, or **AMBUSH**, in the military art, properly denotes a place where soldiers may lie concealed, till they find an opportunity to surprise the enemy.

AMELLUS, in botany, a genus of the syngenesia superflua: receptacle chaffy: down simple: calyx imbricate: florets of the ray undivided. There are three species.

AMEND, or **AMENDE**, in the French customs, a pecuniary punishment imposed by a judge for any crime, false prosecution, or groundless appeal.

AMENDE *honorable* an infamous kind of punishment inflicted in France upon traitors, parricides, or sacrilegious persons, in the following manner. the offender being delivered into the hands of the hangman, his shirt is stripped off and a rope put about his neck, and a taper in his hand; then he is led into court, where he must beg pardon of God, the king, the court, and his country.

AMERCEMENT, or **AMERCIAMENT**, in

law, pecuniary punishment imposed upon offenders at the mercy of the court.

Amercements differ from fines, the latter being certain punishments growing expressly from some statute, whereas the former are imposed in proportion to the fault.

AMERIMNUM, a genus of the diadelphia decandria class and order, of the natural order of the papilionaceæ or leguminosæ. The essential character is: calyx two-lipped; legume compressed, leafy, two-valved, gaping; seeds few and solitary. There are two species: the one a shrub; and the other, A. ebenus, a tree which rises to 14 feet high, with a very thick stem. It is common in the West Indies, where the wood is cut and sent to England under the name of ebony.

AMETHYST. The amethyst is a gem of a violet colour, and great brilliancy, said to be as hard as the ruby or sapphire, from which it only differs in colour. This is called the oriental amethyst, and is very rare. When it inclines to the purple or rosy colour, it is more esteemed than when it is nearer to the blue. These amethysts have the same figure, hardness, specific gravity, and other qualities, as the best sapphires or rubies, and come from the same places, particularly from Persia, Arabia, Armenia, and the West Indies. The occidental amethysts are merely coloured crystals or quartz.

AMYTHYSTEA, in botany, a genus of the diandria monogynia class and order, and of the natural order anticillatæ and labiatæ. This plant is a native of Siberia; it is an annual, and grows to about a foot in height. The flowers are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel, so that they make a fine appearance.

AMIABLE, or **AMICABLE NUMBERS**, are such as are mutually equal to the sum of one another's aliquot parts. Thus the numbers 220 and 284 are amicable numbers. The aliquot parts of 220 are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, and these added together are equal to 284; and the aliquot parts of 284, are 1, 2, 4, 71, 142, which added together are equal to 220.

AMIANTHUS. See ASBESTOS.

AMICUS *curiæ* in law, if a judge be doubtful or mistaken, in a matter of law, a bystander may inform the court on that matter, as *amicus curiæ*, or the friend of the court.

AMMANNIA, in botany, the name of a genus of plants, belonging to the tetrandria monogynia class and order; the flower is composed of four oval patent petals, growing within the cup; and its fruit is a roundish capsule covered by the cup, and containing four cells. There are seven species, all of which seem to be annual, and being natives of hot climates most of them require protection in this country.

AMMI, *bishop's weed,* in botany, a genus of umbelliferous plants, belonging to the pentandria digynia class and order of Linnæus; the flower is rosaceous and composed of heart-like petals; and its fruit is a small roundish and striated capsule, containing two striated seeds, convex on one side. There are three species all annual.

AMMONIA, in chemistry, volatile alkali when in its purest state exists only in the form of gas, and till the recent, and well-known experiments of Sir H. Davy, was supposed to consist of azote and hydrogen. Pure ammonia may be obtained by putting into a retort three parts of quick lime, with one part of salammoniac in powder, and applying the heat of a lamp to the retort; the gas which comes over is ammonia, and must be received in jars filled with mercury. It forms a liquid on being cooled. This substance is often called hartshorn, because it is obtained from distilling the horn of the hart; sometimes it is called spirit of urine, because it may be obtained from urine by the same process; and spirit of salammoniac, since it may be obtained from that salt. Ammonia in the state of gas is transparent and colourless like air; its taste is acrid and caustic like that of the fixed alkalis, but not near so strong, nor does it like them corrode those animal bodies to which it is applied: its smell is remarkably pungent, though not unpleasant, when sufficiently diluted. Its use as a stimulant to prevent fainting is well known. Animals cannot breathe it without death. When this gas is made to pass through red-hot charcoal, part of the charcoal combines with it, and forms a substance known by the name of prussic acid. Ammonia does not combine with the metals, but it changes some of them into oxides, and then dissolves them.

AMMONIA, in chemistry, a resinous substance brought from the East Indies. It is supposed to be a species of the ferula. It is brought to us in drops or granules, and sometimes in large masses composed of a number of these granules connected together. The best kind is of a yellowish colour without, and white within, of an astringent taste, and castor smell.

AMMUNITION, a general term for all warlike provisions, but more especially powder, ball, &c.

Ammunition, arms, utensils of war, gunpowder, imported without licence from his majesty, are, by the laws of England, forfeited, and triple the value.

AMNESTY, in matters of policy, an act by which two parties at variance, promise to pardon and bury in oblivion all that is past.

Amnesty is either general and unlimited, or particular and restrained, though most commonly universal, without condition or exceptions; such as that which passed in Germany at the peace of Osnaburg in the year 1648.

AMOMUM, in botany, a genus of the monandria monogynia class and order. Gmelin enumerates 20 species of this plant. The first, and indeed the principal of these is the A. zinziber, narrow leaved ginger, cultivated by Miller, and flowering in September. It is a native of the East Indies, and other countries of Asia, and is much used there and in the West Indies. The species are all of a very tender nature, and cannot be raised in this country without the aid of the stove.

AMORPHA, in botany, *bastard indigo*, a genus of plants, belonging to the diadelphia decandria class of Linnæus; the flower of which consists of one petal vertically ovated, hollow, and erect; and the fruit is a lunulated pod, of a compressed form, and covered with

tubercles, in which are contained two seeds, of an oblong kidney-like shape. There are two species.

This shrub grows naturally in Carolina, where formerly the inhabitants made a coarse sort of indigo, which occasioned its name of the bastard indigo.

AMPELIS, in ornithology, the chatterer, a genus of birds belonging to the order of passeres; the tongue is furnished with a rim or margin all round, and the bill is conical and straight. There are seven species, all natives of foreign countries, except the garrulus, which is a native both of Europe and the West Indies.

They appear annually in Scotland in February, and feed on the berries of the mountain ash; they are seldom seen farther south than Northumberland. They are gregarious; feed on grapes, where vineyards are cultivated; are easily tamed, and are esteemed delicious food. This species is about the size of the blackbird; the bill is short, thick, and black; on the head is a sharp-pointed crest reclining backwards; the lower part of the tail is black, the end of a rich yellow; the quill feathers are black, the three first tipped with white, the six next have half an inch of their exterior margin edged with fine yellow, the interior with white.

AMPELITES, *Cannel coal.* a solid, dry opaque fossil, very hard, not fusible, but easily inflammable, and burning with a fine white flame. It is found in Lancashire, and different parts of Scotland, where it is called *Parrot Coal.* It is susceptible of a fine polish, and is made into trinkets, and often passes for jet.

AMPHIBIA, the third class of animals in the system of Linnæus, and so called because the *major part* of the animals which it includes can live with equal facility both on land and in water.

This class of animals, from the structure of their organs, and the power they possess of suspending respiration at pleasure, can support a change of element uninjured, and endure a very long abstinence. The lungs differ widely in appearance, from those of other animals. Some of them are possessed of a high degree of productive power, and are soon furnished with new feet, tails, &c. when by accident, those parts have been cut off. They are in general very tenacious of life, and will continue to move, and exert many of the animal functions, even when deprived of the head itself. By far the greater part of them are *oviparous.*

Dr. Parsons classes amphibious animals under two divisions: 1. Such as live chiefly on land, but go occasionally into the water. 2. Such as chiefly inhabit the water, but occasionally go on shore. To the first division belong the phocæ or seal tribe, frogs, lizards, crocodiles, the hippopotamus, &c.: and to the second belong eels, water serpents, or snakes of every kind.

There are some kinds of insects, and also of birds to which the term amphibious is applied.

AMPHISBÆNA, in zoology, a genus of serpent so called, because it moves with either end forward. The body of the amphisbæna has a number of circular annuli, surrounding it from the head to the extremity of the tail; so that it seems composed of a number of narrow and somewhat rounded rings applied close to one another, and having deep furrows between them. There are only two species, the white and the black.

AMPHISCII, among geographers, a name applied to the people who inhabit the torrid zone.

Amphiscii, as the word imports, have their shadows one part of the year towards the north, and at the other towards the south, according to the sun's place in the ecliptic. They are also called Ascii.

AMPHITHEATRE, in antiquity, a spacious edifice built either round or oval, with a number of rising seats, upon which the people used to sit and behold the combats of gladiators, of wild beasts, and other sports.

AMPHITRITE, a genus of worms, of the order mollusca: body projecting from a tube, and annulate: peduncles or feet small, numerous; feelers two, approximate, feathered; no eyes. There are seven species: of which the A. reniformis, with a rounded body and simple feelers, is three inches long, and inhabits the seas about Iceland. The body is of a most beautiful red: head defended by two semicircular arches: plumes fourteen, and alternately red and white: annulations of the body from 80 to 90, with each a minute tubercle on each side: tail, pointed, and not jointed: tube, red, tough, coriaceous, simple, and four inches long.

AMPHORA, in antiquity, a liquid measure in use among the Greeks and Romans. The Roman amphora contained forty-eight sextaries, and was equal to about seven gallons one pint, English wine-measure; and the Grecian, or Attic amphora, contained one-third more.

AMPLITUDE, an arch of the horizon intercepted between the east or west point, and the centre of the sun, or a planet at its rising and setting, and so is either north and south, or ortive and occasive.

AMPLITUDE *Magnetical,* the different rising or setting of the sun, from the east or west points of the compass. It is found by observing the sun, at his rising and setting, by an amplitude-compass.

AMPUTATION, in surgery, the cutting off a limb, or other part of the body, with an instrument.

AMULET, a charm, or preservative against mischief, witchcraft, or diseases. Amulets were made of stone, metal, simples, animals, and, in a word, of every thing which fancy or caprice suggested; and sometimes they consisted of words, characters, and sentences, ranged in a particular order, and engraved upon wood, &c. and worn about the neck, or some other part of the body.

AMYGDALUS, in botany, a genus of the polyandria monogynia class and order; its characters are, that the calyx is a perianthium, one-leafed, tubulous, inferior, quinquefid, deciduous, divisions spreading and obtuse; the corolla of five petals, oblong-ovate, obtuse, concave, inserted into the calyx; the stamina have filaments about 30, filiform, erect, shorter by half than the corolla, inserted into the calyx; anthers simple; the pistillum has a roundish, villose germ, simple style, of the length of the stamens, and headed stigma; the pericarpium is a roundish, villose, large drupe, with a longitudinal furrow; the seed is a nut, ovate, compressed, acute, with prominent

sutures on each side, reticulated with furrows, and dotted with small holes. The nut of the almond is covered with a dry skin; that of the peach with a small pulp. There are seven species with numerous varieties.

The amygdalus, or almond-tree, is cultivated both for the advantage of the fruit, and as being highly ornamental in shrubberies, plantations, and other descriptions of pleasure ground, from its coming into bloom early in the spring. It is, however, less important in the former than the latter point of view, as the fruit is often liable to miscarry in this climate.

AMYRIS, in botany, a genus of the octandria monogynia class and order, and of the natural order terebintaceæ. Of this plant there are nine species, the principal of which are, 1. A. *balsamifera*, or rose-wood. 2. A. *elemifera*, which is a native of South America. 3. A. Gileadensis, a native of Arabia Felix, from which the balm of Gilead is produced. A. Toxifera, or poison wood, a native of the Bahamas.

AMZEL, in ornithology, the name of a bird of the merula or blackbird kind, of which there are two species; the ring-amzel or merula torquata, and the merula montana, called simply the amzel. The ring-amzel is a little larger than the common blackbird. Its back is of a dusky blackish brown, and its throat and breast are beautifully variegated with spots and streaks of white; and the lower part of the throat is adorned with a fine broad white ring, whence the bird has its name.

ANABASIS, in botany, a genus of the pentandria digynia class and order: essen. char.; calyx, three-leaved: cor. five petalled; berry one-seeded, surrounded by a calyx: there are four species.

ANACARDIUM, or CASHEW-NUT TREE: a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 12th order, holoraceæ.

There is but one species of this tree known, viz. Anacardium occidentale. It grows naturally in the West Indies, and arrives at the height of 20 feet in those places of which it is a native The fruit of this tree is as large as an orange; and is full of an acid juice, which is frequently made use of in making punch. To the apex of this fruit grows a nut, of the size and shape of a hare's kidney, but it is much larger at the end which is next to the fruit than at the other. The shell is very hard; and the kernel, which is sweet and pleasant is covered with a thin film. Between this and the shell is lodged a thick, blackish, inflammable liquor, of such a caustic nature in the fresh nuts, that if the lips chance to touch it, blisters will immediately follow. The kernels are eaten raw, roasted, or pickled. The caustic liquor just mentioned is esteemed an excellent cosmetic with the West India young ladies, but they must certainly suffer a great deal of pain in its application. The milky juice of this tree will stain linen of a good black, which cannot be washed out.

ANACHRONISM, in matters of literature, an error with respect to chronology, whereby an event is placed earlier than it really happened

ANACREONTIC *verse*, in ancient poetry, a kind of verse, so called from its being much used by the poet Anacreon. It consists of three feet and a half, usually spondees and iambuses, and sometimes anapests; such is that of Horace,

Lydia dic per omnes.

ANACYCLUS, a genus of the syngenesia polygamia class and order. The essential character is, recept. chaffy: down emarginate: seeds solitary with membranous wings. There are four species, all annuals, and somewhat resembling the chrysanthemum in the flower, foliage, and habits.

ANAGALLIS, in botany, a genus of plants, belonging to the pentandria monogynia class of Linnæus; the flower of which is monopetalous, multifid, and orbicular; the fruit is a globose capsule, containing only one cell, and dividing horizontally into two hemispheres, the seeds are numerous and angular. There are six species.

ANAGRAM, a transposition of the letters of some name, whereby a new word is formed, either to the advantage or disadvantage of the person or thing to which the name belongs: thus, from Galenus is formed Angelus: from James, Simea; and so of others. A miserable species of false wit.

ANALEMMA, in geometry, a projection of the sphere on the plane of the meridian, orthographically made by straight lines and ellipses, the eye being supposed at an infinite distance, and in the east or west points of the horizon.

ANALOGY, in literature, a certain relation and agreement between two or more things, which in other respects are entirely different: thus the foot of a mountain bears an analogy to the foot of an animal, although they are two very different things.

There is likewise an analogy between beings that have some conformity or resemblance to one another: for example, between animals and plants, and between metals and vegetables; but the analogy is still stronger between two different species of certain animals.

ANALOGY, in grammar, denotes the correspondence which a word or phrase bears to the genius and received forms of a language.

ANALYSIS, among logicians, is a method of tracing things back to their origin, and of resolving knowledge into its original principles. The term is used in a general sense to signify the resolution of any thing compounded, into its constituent parts.

Chemical analysis consists of a great variety of operations, performed for the purpose of separating the component parts of bodies. In these operations the most extensive knowledge of such properties of bodies as are already discovered must be applied, in order to produce simplicity of effect, and certainty in the results. Chemical analysis can hardly be executed with success, by one who is not in possession of a considerable number of simple substances in a state of great purity, many of which, from their effects, are called reagents. The word analysis is applied by chemists to denote that series of operations, by which the component parts of bodies are determined, whether they be merely separated, or exhibited apart from each other; or whether these distinctive properties be exhibited by causing them to enter into new combinations, without the perceptible intervention of a separate state The forming of new com-

binations is called synthesis; and, in the chemical examination of bodies, analysis or separation can scarcely ever be effected, without synthesis taking place at the same time.

ANAMORPHOSIS, in perspective and painting, a monstrous projection, or representation of an image on a plain or curve surface, which, beheld at a proper distance, shall appear regular and in proportion.

ANARRHICAS, in natural history, the *wolf-fish*, a genus of fishes of the order apodes, of which there are three species. The wolf-fish frequents the deep part of the sea, and in the spring approaches the coast, in order to deposit its spawn among marine plants. The A. lupus, or ravenous wolf-fish is found in the northern seas; it grows to the length of 14 or 15 feet. The flesh is said to be good, but it is seldom eaten.

ANAS, in ornithology, a genus of birds of the order anseres. The bill is strong, broad, flat, or depressed, and is generally furnished at the extremity with an additional piece called a nail, the edges of the mandibles are marked with sharp teeth; the nostrils small, oval; tongue broad, edges near the base fringed; toes four, three before and one behind; the middle one the longest. According to Gmelin there are about 120 species.

These birds from the swan down to the teal, are all a clean plumaged, and beautiful race of birds. Those which have been reclaimed from a state of nature, and domesticated are highly useful to man; under his protection they breed in great abundance, and without requiring any great portion of his time or care lead their young to the pool, almost as soon as they are hatched, where they instantly begin to search for their food, which at first consists of weeds, worms, and insects. When farther advanced in life they pick up grain, &c. about farm yards which but for them would be lost. They also pick up the grain which is shaken from the over ripe ears in the fields. On this clean and simple food they soon become fat, and their flesh is accounted delicious and nourishing.

ANASTATICA, in botany, the name of a genus of tetradynamious plants of the order siliculosa, called in English, the rose of Jericho: its flower consists of four roundish petals, disposed in the form of a cross; and its fruit is a short bilocular pod, containing in each cell a single roundish seed. Two species annual.

ANATOMY, is the art of examining animal bodies by dissection. It teaches the structure and functions of these bodies, and shews on what life and health depend. The word is derived from the Greek verb *ανατεμνω*, I cut up; yet, we do not, in the common application of the term, confine it to the mere cutting up of dead bodies, but comprehend in it every operation tending to discover the structure and use of any part of the body. There are few subjects which carry with them so strong a degree of interest as the history of anatomy; but, as a bare outline of it would occupy more room than we can afford for the whole of this article, we shall not enter upon it, but would refer the reader to the numerous and well known works on the subject, which enter at large on every point of real importance connected with the study of this useful art. It may, however, be proper to remark here, that the latest improvements in anatomy are not of such a nature, as essentially to interfere with the definitions and views of anatomists during the last century. Great service has, indeed, been rendered to anatomy during that period, by the intense application of men of the highest scientific eminence; and the amazing perfection with which the different parts of the human body have been delineated in the plates of such men as Soemmering, Baillie, and others, will render their names immortal.

As the human body is composed of solids and fluids, anatomy is usually divided into

1. The anatomy of the solids, and
2. The anatomy of the fluids.

The *solids* of the human body consist of,

1. Bones, which give support to the other parts of the body. 2. Cartilages which are softer than the bones, flexible, and elastic. 3. Ligaments, which are more flexible still, and connect the ends of the bones to each other. 4. Membranes, or planes of minutely interwoven fibres. 5. Cellular substance, which is formed of membranes minutely interwoven with each other. 6. Muscles, which are soft and contractile bundles of fibres. 7. Tendons, which generally form the hard and inelastic terminations of muscles. 8. Viscera, portions of the body loosely contained in great cavities. 9. Glands, which separate various fluids from the blood. 10. Vessels, which are membranous canals dividing into branches and transmitting blood and other fluids. 11. Adipose substance, an animal oil contained in the cells of the cellular membrane. 12. The cerebral substance, which is of a peculiar nature. 13. Nerves which are bundles of white cords connected by one end to the brain or spinal marrow, and thence expanded over every part of the body.

The *fluids* of the human body are,

1. Blood, which circulates through the vessels and nourishes the whole fabric. 2. Perspirable matter, excreted by the vessels of the skin. 3. Sebaceous matter, secreted by the glands of the skin. 4. Urine, by the kidneys. 5. Ceruminous matter, secreted by the ceruminous glands of the ear. 6. Tears, by the lachrymal glands. 7. Saliva, by the salival glands of the mouth, &c. 8. Mucus, by the mucous glands of the mouth, &c. 9. Pancreatic juice, by the pancreas. 10. Bile, by the liver. 11. Gastric juice, by the stomach. 12. Oil, by the vessels of the adipose membrane. 13. Synovia, by the synovial glands of the joints. 14. Seminal fluid, by the testes. 15. Milk, by the mammary glands.

Anatomy, from the names of the parts which it considers, is divided into,

1. Osteogeny, which is the doctrine of the growth of the bones. 2. Osteology, or the doctrine of adult bones. 3. Chondrology, or the doctrine of cartilages. 4. Syndesmology, or the doctrine of ligaments. 5. Myology, or the doctrine of muscles. 6. Bursalogy, or the doctrine of the bursæ muscosæ. 7. Splanchnology, or the doctrine of the viscera. 8. Angiology, or the doctrine of the vessels. 9. Adenology, or the doctrine of the glands. 10. Neurology, or the doctrine of the nerves, &c.

OSTEOGENY.

Osteogeny treats of ossification, or the growth of bones.

It commences in the flat bones of the head

in the form of a radii, which diverge from a common centre.—In the middle of the cylindri-

by a number of minute points.

OSTEOLOGY.

It has been said, that bones consist of fibres and lamellæ. This doctrine is nevertheless false, for the celebrated Scarpa of Pavia has demonstrated that a cellular reticular, and vascular parenchyma constitutes the basis of the earthy matters to which bones owe their solidity, and that consequently their intimate structure is the same with that of the soft parts of the body.

The long cylindrical or triangular bones consist of two epiphyses, which form their teration, and are internally spongy, and of a diaphysis between the two epiphyses, of a compact structure, internally reticular, where its net-work supports the bags of the marrow. The broad or flat bones of the body are extremely irregular in their form.

The periosteum of bones is that membrane which covers them, and conducts to them vessels and nerves.

The marrow of bones is an oleaginous fluid contained within the membranous bags, but its use is totally unknown.

Numerous blood vessels pass into bones by small holes on their surface; and the manner in which these are distributed is beautifully demonstrated by observing the red tinge they assume in animals with whose food madder is mixed.

The bones of the skull are eight in number; the os frontis, the two ossa parietalia, the os occipitis, the two ossa temporum, the os sphenoides, and the os ethmoides. The two last of these are said to be common to the head and face, because they constitute a part of both. We shall consider them in the order in which they are here enumerated.

The os frontis is placed in the fore part of the skull, and forms the brow and the upper part of the orbits of the eyes. It is convex externally, and concave internally, and has a serrated semicircular edge, which is turned upward, while its lower part is extremely irregular.

The ossa parietalia form all the superior, and some of the lateral parts of the skull. They are convex externally, concave internally, and of an irregular quadrangular form. Their sides are anterior, posterior, superior, and inferior, which last is of a semicircular form.

The os occipitis is situated in the lower and back part of the skull. It is convex externally, concave internally, and irregularly rhomboidal in its form.

The ossa temporum are situated at the lower part of the sides and base of the cranium, and are of a very irregular figure. Their upper part, named os squamosum, is externally smooth, and has a thin semicircular edge; their posterior part, called pars mammillaris, is thicker and less regular; and their inferior part becoming smaller, and extending horizontally, obtains the name of os petrosum, from its hardness.

The os sphenoides is situated in the middle of the base of the skull, and extends across it from one temple to the other. It is extremely irregular in its figure.

The os ethmoides is placed in the middle of the fore part of the basis of the cranium.

nares; two ossa turbinata, which are external to, the last; the cells of the bone, which are placed still more externally; and the ossa plana, which are most external, and assist in the formation of the inner sides of the orbits.

These bones of the cranium are connected by certain sutures or serrated junctions: which are, the coronal, ascending over the fore-part of the skull; the lambdoidal, placed at its posterior part; the sagittal, joining these two in the middle of the upper part of the skull; the squamous, which are placed on each side; and the sphenoidal and ethmoidal, surrounding the bones of the same name.

The bones of the face are in all fourteen; and of these the ossa nasi form the arch of the nose: the ossa lachrymalia are seated at the fore part of the inner edge of the orbits of the eyes: the ossa mallarum constitute the prominences of the cheeks; the ossa maxillaria superiora, form the upper jaw, and contain the sixteen upper teeth: the ossa palati, are situated at the posterior part of the palate, nares and orbit: the ossa turbinata inferiora resemble those of the ethmoides: the vomer is a thin bone which completes the division of the nares: the maxilla inferiora is the bone of the lower jaw, containing the inferior sixteen teeth.

The teeth are formed of a bony substance and covered with an enamel. Each tooth consists of a head, a neck, and one or more fangs, or roots, sunk in the jaw. There are three classes, viz. four incisores, or the front teeth of each jaw; two cuspidati, on each side the former; four bicuspides behind the last; and six molares behind these. The last of the molares is termed dens sapientiæ.

The os hyoides, or bone of the tongue, resembles in form the Greek υ, whence its name. It consists of a body, two cornua, and two appendices.

The bones of the trunk consist of those of the spine, the pelvis, and the thorax.

The spine consists of twenty-four true or moveable, and five false or immoveable vertebræ, likewise denominated the os sacrum, and of one small bone named os coccygis. The true vertebræ consist of a body, a ring behind the body transmitting the spinal marrow, and of seven processes, four of which are articular, or serve to connect the vertebræ with each other; and three are for muscular attachment: of these two are termed transverse, from their projecting laterally; and one spinous, from its forming the ridge or spine of the back. The true vertebræ are also divided into classes. The first class is the cervical, including the first seven; the first of which is termed atlas, the second dentatus. The second class is the dorsal, consisting of twelve, which are larger than the cervical, and are distinguished by having their sides and transverse processes depressed for connection with the ribs. The third class is the lumbar, consisting of five, which are larger than any of the superior ones. The os sacrum resembles a reversed pyramid, somewhat concave internally and convex externally. It constitutes the posterior part of the pelvis. The os coccygis, in form, very

much resembles the os sacrum, of which it is merely an appendix fixed to its lower part.

The pelvis, or inferior cavity of the trunk, in addition to the two bones last mentioned, consists of the two ossa innominata.

The thorax, or superior cavity of the trunk, is formed by a long narrow bone, named sternum, and by the twenty-four ribs, which are long, narrow, and curved bones, attached by their heads and posterior ends to the vertebræ. The upper seven, from their being attached in the former way, are named true ribs; the inferior five are termed false.

The shoulder consists of two bones, viz. the clavicula and the scapula. The clavicula or collar bone is situated between the top of the sternum or breast-bone and the extremity of the shoulder, and sometimes resembles in form an Italic *f*. The scapula is a triangular flat bone, which forms the greatest part of th shoulder. It is situated behind the upper part of the thorax.

The arm has only one bone, termed the os humeri, the upper part of which is received by the scapula, and its lower part terminates in two condyles.

The fore arm consists of two bones, viz. the radius and ulna, the latter of which allows of flexion and extension, while at the same time it serves as an axis to the radius, which so revolves around it as to effect the motions of the hand.

The bones of the hand are divided into the carpus, metacarpus, fingers and thumb. The carpus consists of eight small bones, named schaphoides, lunare, cuneiforme, and piziforme, which form the first row; and trapezium, which form the second. The metacarpus consists of four bones, having bases attached to the carpus, and round heads for articulation with the fingers. Each of the fingers, as well as the thumb, consists of three bones; all of which, except the terminating ones, possess a head and base for articulation with their fellows.

The bones of the lower extremities consist of those of the thigh, leg, and foot.

The thigh has only one, termed os femoris, the upper part of which forms a round head, received by a cup-like cavity, called acetabu- [illegible] of the os innominatum. Below thi [illegible] neck of the bone, and at its base two protuberances called trochanters.

The bones of the leg are three, viz. the patella or knee-pan; the tibia, which has a triangular body, and terminates inferiorly in the malleolus internus, or inner ankle; and the fibula a long triangular bone on the outside of the leg, articulated above to the tibia, and below terminating in the malleolus externus, or outer ankle.

The bones of the foot are those of the tarsus, metatarsus, and toes. The tarsus consists of seven bones. The metatarsus is composed of five, having broad bases and round heads. The phalanges of the toes are three in number: each of their bones are shorter than those of the finger, and the great toe possesses only two.

CHONDROLOGY.

Under this head it is only necessary to state that, in the recent subject, the articular surfaces of bones are covered by cartilage. Interarticular cartilages are also placed in some of them, as in the joint of the lower jaw, of the clavicle and sternum, of the knee, &c

SYNDESMOLOGY.

Capsular ligaments surround all the joints; but those which possess the hinge-like motion have also lateral ligaments to render them firm, while those possessing motion in every direction have ligaments internal to the capsular.

BURSALOGY.

The mucous bags, called bursæ mucosæ, are placed wherever tendons pass over each other or over any solid part, and serve the purpose of lubricating these tendons.

MYOLOGY.

Of the muscles of the teguments of the cranium.

1. The occipito-frontalis arises from the transverse ridge of the os occipitis; and is inserted into the orbicularis palpebrarum of each side. Its use is to pull the skin of the head backwards. 2. The corrugator supercilii arises from the internal angular process of the os frontis, and is inserted into the inner and inferior fleshy part of the occipito-frontalis muscle. Its use is to draw the eyebrow of that side towards the other.

Of the muscles of the ear.

The common muscles are,

1. The attolens aurem, arises from the tendon of the occipito-frontalis, and is inserted into the upper part of the ear. 2. The anterior auris arises near the posterior part of the zygoma, and is inserted into a small eminence on the back of the helix. 3. The retrahentes auris arise from the root of the mastoid process, and are inserted into that part of the back of the ear which is opposite to the septum conchæ.

The proper muscles are,

1. The helicis major arises from the acute process of the helix, and is inserted a little above. 2. The helicis minor arises from the inferior and anterior part of the helix, and is inserted into the crus of the helix near its fissure. 3. The tragicus arises from the root of the concha, and is inserted into the point of the tragus. 4. The antitragicus arises from the root of the helix, and is inserted into the tip of the antitragus. 5. The transversus auris arises from the prominent part of the concha on the dorsum of the ear, and is inserted into the contiguous part of the antihelix.

The muscles of the internal ear are three

1. The laxator tympani arises from the spinous process of the sphenoid bone, and is inserted into the long process of the malleus. 2. The tensor tympani arises from the extremity of the eustachian tube, and is inserted into the posterior part of the handle of the malleus. 3. The stapedius arises from the posterior part of the tympanum, and is inserted into the posterior part of the head of the stay

Of the muscles of the eye-lids.

The palpebræ, or eye-lids, have one muscle common to both, and the upper eye-lid one proper to itself.

1. The orbicularis palpebrarum which rises from the outer edge of the orbit, and is inserted into the nasal process of the superior maxillary bone. 2. The levator palpebræ superioris rises from the upper part of the foramen opticum,

and is inserted into the tarsus of the upper eye-lid.

Muscles of the eye-ball.

The muscles which move the globe of the eye are six, viz. four straight and two oblique.

The four straight muscles arise from the bottom of the orbit around the foramen opticum of the sphenoid bone; they are inserted at the fore part of the globe of the eye into the anterior part of the tunica sclerotica: their names are, the levator oculi, depressor oculi, adductor oculi, and abductor oculi.

The oblique muscles are two:

1. The obliquus superior, or trochlearis, arises from the edge of the foramen opticum at the bottom of the orbit, and is inserted into the tunica sclerotica, between the attollens and optic nerve. 2. The obliquus inferior arises from the outer edge of the orbitar process of the superior maxillary bone, and is inserted into the sclerotica, between the abductor and optic nerve.

Of the muscle of the nose.

There is only one muscle on each side that can be called proper to the nose, though it is affected by several muscles of the face.

The compressor naris arises from the root of the ala nasi externally, and is inserted into the anterior extremity of the os nasi.

Muscles of the mouth and lips.

The mouth has nine pair of muscles, inserted into the lips, and a common one formed by the termination of these, viz. three above, three below, three outwards, and the common muscle surrounding the mouth.

The three above are,

1. The levator anguli oris which rises from the superior maxillary bone, and is inserted into the angle of the mouth. 2. The levator labii superioris alæque nasi arises by two origins; the first from the external part of the orbitar process of the superior maxillary bone; the second from the nasal process of the superior maxillary bone. The first and shortest portion is inserted into the upper lip and orbicularis labiorum; the second and longest into the upper lip and outer part of the ala nasi. 3. The depressor labii superioris alæque nasi arises anteriorly from the os maxillare superior and is inserted into the upper lip and root of the ala nasi.

The three below are,

1. The depressor anguli oris, rises from the lower edge of the maxilla inferior, and is inserted into the edge of the under lip. 3. The levator labii inferioris rises anteriorly from the lower jaw, and is inserted into the under lip and skin of the chin.

The three outward are,

1. The buccinator, which rises from the lower jaw; and is inserted into the angle of the mouth. 2. The zygomaticus major arises from the os malæ, and is inserted into the angle of the mouth. 3. The zygomaticus minor rises above the origin of the former, and is inserted near the corner of the mouth.

The common muscle is,

The orbicularis oris. This muscle is, in a great measure, formed by the muscles that move the lips, and surrounds the mouth like a sphincter.

Muscles of the lower jaw.

The lower jaw has four pair of muscles, viz. two which are seen on the side of the face, and two concealed by the angle of the jaw.

1. The temporalis arises from the parietal bone, and the temporal fossa of the cranium, and is inserted into the coronoid process of the lower jaw. 2. The masseter arises from the inferior and interior part of the zygoma, and is inserted into the outside of the angle of the lower jaw. 3. The pterygoideus internus arises from the pterygoid fossa, and is inserted into the angle of the lower jaw internally. 4. The pterygoideus externus arises chiefly from the outer side of the external pterygoid process, and is inserted into the fore part of the condyloid process.

The muscles which appear about the anterior part of the neck.

On the side of the neck are two muscles or layers:

1. The musculus cutaneus vulgo platysma myoides arises from the cellular substance that covers the upper part of the deltoid and pectoral muscles, and is inserted into the integuments covering the side of the lower jaw. 2. The sterno-cleido mastoideus arises by two distinct origins; the anterior from the top of the sternum; the posterior from the upper and anterior part of the clavicle; both unite to be inserted into the mastoid process.

Muscles situated between the lower jaw and os hyoides.

There are four layers before, and two muscles at the side. The four layers are,

1. The digastricus arises from the fossa at the root of the mastoid process of the temporal bone, and is inserted into a roughness at the inferior edge of the chin. 2. The mylo-hyoideus arises from the inside of the lower jaw, and is inserted into the basis of the os hyoides. 3. The genio-hyoideus arises from the middle of the lower jaw internally, and is inserted into the basis of the os hyoides. 4. The genio-hyo-glossus arises from the inside of the middle of the lower jaw, and is inserted into all the length of the tongue, and base of the os hyoides.

The two muscles at the side are,

1. The hyo-glossus arises from the base, cornu, and appendix of the os hyoides, and is inserted into the side of the tongue. 2. The lingualis arises from the root of the tongue laterally, and is inserted into the tip of the tongue.

Muscles situated between the os hyoides and trunk.

1. The sterno-hyoideus arises from about the extremity of the first rib, and is inserted into the base of the os hyoides. 2. The omohyoideus arises from the superior costa of the scapula, near the semilunar nitch, and is inserted into the base of the os hyoides.

The second layer consists of three muscles:

1. The sterno-thyroideus arises from the uppermost bone of the sternum, and is inserted into the inferior edge of the thyroid cartilage. 2. Thyreo-hyoideus arises opposite to the former, and is inserted into part of the basis, and almost all the cornu of the os hyoides. 3. The crico-thyroideus arises from the side and fore part of the cricoid cartilage, and is inserted

into the lower part of the thyroid cartilage; and inferior cornu.

Muscles situated between the lower jaw and os hyoides laterally.

They are five in number.

1. The stylo-glossus rises chiefly from the styloid process, and is inserted into the root, side and tip of the tongue. 2. The stylo-hyoideus rises from the inferior part of the styloid process, and is inserted into the os hyoides between its base and cornu. 3. The stylo-pharyngeus rises from the root of the styloid process, and is inserted into the side of the pharynx and back of the thyroid cartilage.

The two from the pterygoid process are,

1. The circumflexus, or tensor palati, rises chiefly from the spinous process of the sphenoid bone, and spreads into a broad membrane, which is inserted into the velum pendulum palati. 2. The levator palati rises from the pars petrosa of the temporal bone, and is inserted into the velum pendulum palati.

Muscles situated about the entry to the fauces.

There are two on each side, and a single one in the middle.

The two on each side are,

1. The constrictor isthmi faucium rises from the side of the tongue: it is inserted into the middle of the velum pendulum palati. 2. The palato-pharyngeus rises chiefly from the middle of the velum pendulum palati; it is inserted into the edge of the upper and back part of the thyroid cartilage.

The one in the middle is,

The azygos uvulæ, which rises from the extremity of the suture, which joins the palate bones, and is inserted into the tip of the uvula.

Muscles situated on the posterior part of the pharynx.

1. The constrictor pharyngis inferior rises from the side of the thyroid, and from the cricoid cartilage, and is inserted into the middle of the pharynx 2. The constrictor pharyngis medius rises from the appendix and cornu of the os hyoides, and is inserted into the middle of the cuneiform process of the os occipitis. 3. The constrictor pharyngis superior rises from the cuneiform process of the os occipitis, from the pterygoid process of the sphenoid bone and from the upper and under jaw. It is inserted into a white line in the middle of the pharynx.

Muscles situated about the glottis.

1. The cryco-arytænoideus posticus, rises in the back part of the cricoid cartilage, and is inserted into the posterior part of the base of the arytenoid cartilage. 2. The crico-arytænoideus lateralis, rises from the cricoid cartilage laterally, and is inserted into the side of the base of the arytenoid cartilage. 3. The thyreo-arytænoideus rises from the under and back part of the middle of the thyroid cartilage, and is inserted into the arytenoid cartilage. 4. The arytænoideus obliquus rises from the base of one arytenoid cartilage, and is inserted near the tip of the other.

The single muscle is,

The arytænoideus transversus rises from the side of one arytenoid cartilage, and is inserted into the other.

Muscles situated in the fore part of the abdomen.

These consist of three broad layers on each side; always a long one, and generally also a short one, on each side the linea alba.

The three layers are,

1. The obliquus descendens externus, rises by eight heads from an equal number of inferior ribs, and is inserted into the whole length of the linea alba. 2. The obliquus ascendens internus rises from all the spine of the ilium, the os sacrum, the three undermost lumbar vertebræ, and from Poupart's ligament. It is inserted into the cartilago ensiformis, and into the cartilages of the seventh and those of all the false ribs. 3. The transversalis rises from the inner part of the cartilages of the seven lower ribs, from the spine of the os ilium internally, and from the tendon of the external oblique muscle. It is inserted into the cartilago ensiformis, and into the whole length of the linea alba.

The long muscle in the middle is,

The rectus abdominis, which rises from the symphysis pubis, and is inserted into the cartilages of the three inferior true ribs.

The short muscle in the middle is the pyramidalis rising with the rectus, and inserted into the linea alba, half-way between the os pubis and umbilicus.

Muscles about the male organs of generation.

Each of the testes has one muscle.

The cremaster rises from the lower part of the internal oblique, and is inserted into the tunica vaginalis of the testis.

The penis has three pair of muscles.

1. The erector penis rises from the tuberosity of the ischium, and is inserted into the membrane covering the corpora cavernosa penis. 2. The accelerator urinæ, or ejaculator seminis, rises from the sphincter ani and membranous part of the urethra, and from the crus penis. It is inserted into a line in the middle of the bulb. 3. Transversus perinei rises from the membrane covering the tuberosity of the ischium, and is chiefly inserted into the accelerator urinæ.

There is often a fourth muscle, named,

4. Transversus perinei alter, which rises behind the former, runs more forward, and is inserted into the fore part of the accelerator urinæ.

Muscles of the anus.

The anus has a single muscle, and one pair. The single muscle is,

The sphincter ani, which rises from the verge of the anus, and is inserted, before, into the perineum, acceleratores urinæ, and transversi perinei; behind, into the extremity of the os coccygis.

The levator ani rises within the pelvis, and is inserted into the sphincter ani, &c.

Muscles of the female organs of generation.

The clitoris has one pair.

The erector clitoridis, rises internally from the crus of the ischium; and is inserted into the clitoris.

The vagina has one pair.

The sphincter vaginæ, rises from the sphincter ani, and is inserted into the crus and body of the clitoris

The transversus perinei, sphincter ani, and levator ani, in the female almost precisely resemble the same muscles in the male.

Muscles within the pelvis.

Of these there are two pairs.

1. Obturator internus, rises from the internal circumference of the thyroid foramen, and is inserted into the top of the trochanter major. 2. The coccygeus, rises from the spinous process of the os ischium, and is inserted into the end of the sacrum, and into the os coccygis.

Muscles situated within the cavity of the abdomen.

They consist of a single muscle and four pairs.

The diaphragm is a broad thin muscle forming a septum between the thorax and abdomen. It is commonly divided into two portions.

1. The superior or greater muscle rises from the cartilago ensiformis, the cartilages of the seventh and all the inferior ribs, and is inserted into a tendon situated in the middle of the septum. 2. The inferior or lesser muscle of the diaphragm rises from the second, third, and fourth lumbar vertebræ, by eight heads; and is inserted into the posterior part of the middle tendon

The four pairs are,

1. The quadratus lumborum which rises from the posterior part of the spine of the ilium, and is inserted into the transverse processes of the lumbar vertebræ, into the last rib, and the last dorsal vertebra. 2. Psoas parvus, rises from the sides of the two upper lumbar vertebræ, and is inserted into the brim of the pelvis. 3. Psoas magnus, rises from the side of the body and transverse process of the last dorsal vertebra, and from all the lumbar. It is inserted into the trochanter minor. 4. The iliacus internus rises from the transverse process of the last vertebra of the loins, from the crista, and from the hollow part of the ilium. It is inserted along with the former.

Muscles on the fore part of the thorax.

These consist of two layers, and the first layer of one muscle.

The pectoralis major rises from the extremities of the fifth and sixth ribs, from the sternum, and from half the anterior part of the clavicle It is inserted into the groove of the biceps.

The second layer consists of three muscles.

1. The subclavius rises from the cartilage of the first rib, and is inserted into the inferior part of the clavicle. 2. The pectoralis minor, rises from the upper edge of the third, fourth, and fifth ribs, and is inserted into the coracoid process of the scapula. 3. The serratus magnus. rises from the nine superior ribs, and is inserted into the whole base of the scapula.

Muscles placed between the ribs.

These are the intercostales externi et interni, which, rising in two layers from the lower edge of one rib, are inserted into the upper edge of another.

The muscles within the thorax are one pair.

The triangularis, or sterno-costalis, rises from the cartilago ensiformis, and the inferior part of the edge of the middle bone of the sternum. It is inserted into the lower edge of the cartilages of the third, fourth, and fifth ribs.

Muscles on the fore part of the neck, close to the vertebræ.

They consist of one layer, formed by four muscles.

1. Longus colli, rises from the three superior laterally, and from the transverse process of the third, fourth, fifth, and sixth cervical. It is inserted into the fore part of the vertebræ of the neck. 2. The rectus capitis internus major, rises from the transverse processes of the third, fourth, fifth, and sixth cervical vertebræ, and is inserted into the cuneiform process of the os occipitis. 3. Rectus capitis internus major, rises from the body of the atlas, and is inserted into the condyloid process of the os occipitis. 4. The rectus capitis lateralis, rises from the tip of the transverse process of the atlas, and is inserted into the os occipitis external to the foramen magnum.

On the side of the neck,

1. Scalenus anticus rises from the fourth, fifth, and sixth transverse processes of the neck, and is inserted into the upper side of the first rib. 2. Scalenus medius rises from the transverse processes of the cervical vertebræ, and is inserted into the first rib. 3. Scalenus posticus rises from the fifth and sixth transverse processes of the cervical vertebræ, and is inserted into the upper edge of the second rib.

Muscles situated on the back of the trunk.

The following muscles are described as they appear on dissection.

1. The trapezius, rises from the os occipitis, and also from the spinous processes of the two inferior cervical, and from those of all the dorsal vertebræ. It is inserted into the posterior half of the clavicle, the acromion, and the spine of the scapula. 2. The latissimus dorsi rises from the back of the spine of the ilium, the spinous processes of the sacrum and lumbar vertebræ, and from the seven inferior ones of the vertebræ of the back: also from the extremeties of the inferior ribs. It is inserted into the edge of the groove of the tendon of the biceps. 3. The serratus posticus inferior rises from the spinal processes of the two inferior dorsal vertebræ, and from the three superior lumbar. It is inserted into the lower edges of the four inferior ribs. 4. The rhomboideus is divided into two portions. 1. The rhomboideus major, which rises from the spinous processes of the five superior vertebræ of the back, and is inserted into all the basis of the scapula below the spine. 2. Rhomboideus minor, which rises from the spinous processes of the three inferior vertebræ of the neck, and the ligamentum nuchæ. It is inserted into the base of the scapula, opposite to its spine. 5. The serratus superior posticus, rises from the spinous processes of the three last vertebræ of the neck, and the two upper of the back. It is inserted into the second, third, fourth, and fifth ribs. 6. The levator scapulæ rises from the transverse processes of the superior vertebræ of the neck. It is inserted into the superior angle of the scapula.

On the neck,

1. The splenius, rises from the four superior spinous processes of the vertebræ of the back, the five inferior of the neck, and adheres to the

ligamentum nuchæ. It is inserted into the five superior transverse processes of the cervical vertebræ, the back of the mastoid process, and the os occipitis. 2. The complexus rises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck. It is inserted into the os occipitis. 3. The trachelo-mastoideus, rises from the transverse processes of the three uppermost dosal and five lowermost cervical vertebræ. It is inserted into the back of the mastoid process. 4. The transversalis colli, rises from the transverse processes of the five uppermost vertebræ of the back. It is inserted into the transverse processes of the cervical vertebræ, except the first and the last. 5. The rectus capitis posticus major, rises from the spinous process of the dentata. It is inserted into the os occipitis. 6. The rectus capitis posticus minor rises from the back part of the atlas. It is inserted behind the foramen magnum. 7. The obliquus capitis superior, rises from the transverse process of the atlas. It is inserted into the os occipitis, behind the back of the mastoid process. 8. The obliquus capitis inferior, rises from the spinous process of the dentata, and is inserted into the transverse process of the atlas.

On the back near the spine:

1. The sacro-lumbalis rises with the longissimus dorsi, and is inserted into the curve of all the ribs. 2. The longissimus dorsi, rises from the side, and all the spines of the sacrum; the posterior spine of the ilium, from the spines, and from the transverse processes of the lumbar vertebræ. It is inserted into the transverse processes of the dorsal vertebræ, and the lower edge of all the ribs except the two inferior. 3. The spinalis dorsi, rises from the spines of the two uppermost lumbar vertebræ, and the three inferior dorsal vertebræ. It is inserted into the spines of the nine upper dorsal vertebræ except the first. 4. The semispinalis dorsi rises from the transverse processes of the seventh, eighth, ninth, and tenth dorsal vertebræ, and is inserted into the spines of all the dorsal vertebræ above the eighth, and the two lower cervical vertebræ.

On the neck:

1. The semispinalis colli rises from the transverse processes of the six uppermost vertebræ of the back. It is inserted into the spines of all the cervical vertebræ, except the first and last. 2. The multifidus spinæ, rises from the side and spine of the sacrum, and the posterior part of the ilium; from all the oblique and transverse processes of the lumbar vertebræ; all the transverse processes of the dorsal vertebræ; and from those of the cervical, except the three first. It is inserted into all the spines of the lumbar, dorsal, and cervical vertebræ, except the first. 1. The interspinales colli rise from the spine of the inferior vertebræ of the neck, and ascend to be inserted into the superior vertebræ. 2. The intertransversales colli, rise from the inferior transverse process of each vertebra of the neck, and first of the back, and are inserted into the superior transverse processes. 3, 4, and 5. The interspinales dorsi et lumborum, and the intertransversales dorsi, are rather small tendons than muscles. 6. The intertransversales lumborum, are four small bundles which fill up the spaces between the transverse processes of the lumbar vertebræ.

Muscles on the shoulder.

1. Deltoides, rises from the clavicle, processus, acromion, and spine of the scapula. It is inserted into the anterior and middle part of the os humeri. 2. Supraspinatus, rises from the basis, spine, and upper costa of the scapula. It is inserted into a large tuberosity at the head of the os humeri. 3. Infranspinatus, rises from the basis and spine of the scapula. It is inserted into the upper and middle part of the tuberosity. 4. Teres minor, rises from the interior costa of the scapula. It is inserted into the lower part of the tuberosity. 5. Teres major, rises from the inferior angle, and costa of the scapula. It is inserted into the ridge at the inner side of the groove formed for the long head of the biceps. 6. Subscapularis, rises from the basis, superior and inferior costæ of the scapula. It is inserted into the upper part of a small tuberosity at the head of the os humeri. 7. Coraco-brachialis, rises from the coracoid process of the scapula. It is inserted into the inner side of the os humeri.

Muscles on the arm.

1. Biceps flexor cubiti, rises from the coracoid process, and the glenoid cavity of the scapula. It is inserted into the tuberosity at the upper end of the radius. 2. Brachialis internus, rises from the os humeri, below, the tendon of the deltoides. It is inserted into the coronoid process of the ulna, and olecranon. 3. Triceps extensor cubiti, rises from the inferior costa of the scapula; from the upper and outer part of the os humeri; and the back part of that bone.

Muscles on the fore arm.

1. Supinator longus, rises from the ridge of the os humeri, a little above its outer condyle. It is inserted into the radius near its styloid process. 2. Extensor carpi radialis longus, rises below the origin of the supinator longus. It is inserted into the upper part of the metacarpal bone of the middle finger. 3. Extensor carpi radialis brevis rises from the outer condyle and the upper part of the radius. It is inserted into the back of all the bones of the four fingers. 4. Extensor digitorum communis, rises from the outer condyle of the os humeri It is inserted into the back of all the bones of the four fingers. 5. Extensor minimi digiti, rises from the outer condyle of the os humeri. It is inserted into the bones of the little finger. 6. Extensor carpi ulnaris rises from the condyle of the os humeri. It is inserted into the metacarpal bone of the little finger. 7. Anconaeus, rises from the outer condyle of the os humeri. It is inserted into the outer edge of the ulna. 8. Flexor carpi ulnaris, rises from the inner condyle of the os humeri, and anterior edge of the olecranon. It is inserted into the os pyriforme. 9. Palmaris longus, rises from the inner condyle of the os humeri. It is inserted into the internal annular ligament. 10. Flexor carpi radialis, rises from the inner condyle of the os humeri. It is inserted into the metacarpal bone of the fore finger. 11. Pronator radii brevis, rises from the outer condyle of the os humeri, and coronoid process of the ulna. It is inserted into the radius, near its middle. 12. Flexor sublimis perforatus, rises from the inner condyle of the os humeri, inner edge of the coronoid process of the ulna, and upper part of the radius. It is inserted into

the second bone of each finger. 13. Supinator radii brevis, rises from the outer condyle of the os humeri, and the ulna. It is inserted into the radius. 14. Abductor pollicis longus, rises from the ulna, interosseous ligament, and radius. It is inserted into the os trapezium, and first bone of the thumb. 15. Extensor minor pollicis, rises from the ulna, and interosseous ligament and radius. It is inserted into the second bone of the thumb. 16. Extensor major pollicis, rises from the ulna and interosseous ligament. It is inserted into the third and last bone of the thumb. 17. Indicator rises from the middle of the ulna. It is inserted into the metacarpal bone of the fore finger. 18. Flexor profundus perforans rises from the upper and fore part of the ulna, and interosseous ligament. It is inserted into the fore part of the last bone of each of the fingers. 19. Flexor longus pollicis; rises from the upper and fore part of the radius. It is inserted into the last joint of the thumb. 20. Pronator radii quadratus, rises from the ulna. It is inserted into the radius, opposite to its origin.

Muscles of the hand.

1. Lumbricales, rise from the tendons of the perforans. They are inserted into the tendons of the extensor digitorum communis. 2. Abductor brevis pollicis, rises from the internal annular ligament, os scaphoides, and one of the tendons of the abductor longus pollicis. It is inserted into the outer side of the second bone of the thumb. 3. Opponens pollicis, rises from the inner and anterior part of the internal annular ligament, and the os scaphoides. It is inserted into the first bone of the thumb. 4. Flexor brevis pollicis, rises from the os trapezoides, internal annular ligament, os magnum, and os unciforme. It is inserted into the ossa sesamoidea and second bone of the thumb. 5. Abductor pollicis, rises from the metacarpal bone of the middle finger. It is inserted into the basis of the second bone of the thumb. 6. Abductor indicis, rises from the inner side of the first bone of the thumb, and from the os trapezium. It is inserted into the first bone of the fore finger posteriorly. 7. Palmaris brevis, rises from the internal annular ligament, and aponeurosis palmaris. It is inserted into the os pisiforme, and the skin covering the abductor minimi digiti. 8. Abductor minimi digiti rises from the internal annular ligament and os pisiforme. It is inserted into the side of the first bone of the little finger. 9. Flexor parvus minimi digiti, rises from the os unciforme, and internal annular ligament. It is inserted into the first bone of the little finger. 10. Abductor metacarpi minimi digiti, rises from the os unciforme, and internal annular ligament. It is inserted into the metacarpal bone of the little finger. 11. Interossei interni, situated between the metacarpal bones. They are inserted into the roots of the fingers. 12. Interossei externi, situated between the metacarpal bones on the back of the hand. They are inserted into the roots of the fingers.

Muscles on the upper part of the thigh.

1. Glutæus maximus, rises from the spine of the ilium, posterior sacro-ischiatic ligaments, os sacrum, and os coccygis. Inserted into the upper part of the linea aspera of the os femoris. 2. Glutæus medius, rises from the spine and superior surface of the ilium. It is inserted into the outer and back part of the great trochanter. 3. Glutæus minimus, from the outer surface of the ilium. It is inserted into the upper and interior part of the great trochanter. 4. Pyriformis, rises from the anterior part of the os sacrum. It is inserted into the root of the trochanter major. 5. Gemini, rises by two portions, one from the outer surface of the spine of the ischium, the other from the tuberosity of the ischium, and posterior sacro-ischiatic ligament. It is inserted into the pyriformis. 6. Obturator internus, rises from the inner border of the foramen thyroideum. It is inserted into the same cavity with the former. 7. Quadratus femoris, rises from the tuberosity of the ischium. It is inserted between the trochanter major and trochanter minor.

Muscles on the thigh.

1. Biceps flexor cruris, rises by two heads: one from the tuberosity of the ischium, the other from the linea aspera, near the insertion of the glutæus maximus. It is inserted into the upper and back part of the fibula. 2. Semitendinosus, rises from the tuberosity of the ischium. It is inserted into the upper and inner part of the tibia. 3. Semi-membranosus, rises from the tuberosity of the ischium. It is inserted into the head of the tibia. 4. Tensor vaginæ femoris, rises from the superior and anterior spinous process of the ilium. It is inserted into the inner side of the fascia lata. 5. Sartolius, rises from the superior and anterior spinous process of the ilium. It is inserted into the upper and inner part of the tibia. 6. Rectus, rises by two tendons; one from the anterior and inferior spinous process of the illium, the other from the posterior edge of the cotyloid cavity It is inserted into the rotula. 7. Gracilis rises from the fore part of the ischium and pubis. It is inserted into the upper and inner part of the tibia. 8. Vastus externus, rises from the anterior and lower part of the great trochanter, and, the outer edge of the linea aspera. It is inserted into the upper and outer part of the rotula. 9. Vastus internus, rises from the inner edge of the linea aspera. It is inserted into the outer and inner part of the rotula. 10. Cruræus, rises from the outer and anterior part of the lesser trochanter. It is inserted into the upper part of the rotula. 11. Pectinalis, rises from the anterior edge of the os pubis. It is inserted into the upper and fore part of the linea aspera. 12. Adductor longus femoris, rises from the upper and fore part of the os pubis. It is inserted near the middle and back part of the linea aspera. 13. Adductor brevis femoris, rises from the fore part of the ramus of the os pubis. It is inserted into the inner and upper part of the linea aspera. 14. Adductor magnus femoris rises from the lower and fore part of the ramus of the os pubis. It is inserted into the whole length of the linea aspera. 15. Obturator externus rises from the obturator ligament. It is inserted into the os femoris.

Muscles on the leg

1. Gastrocnemius externus, rises by two heads; one from the inner condyle, the other

from the outer condyle of the os femoris. It is inserted by a great round tendon, common to this and the following muscle. 2. Gastrocnemius internus rises by two heads; one from the back part of the head of the fibula, the other from the upper and back part of the tibia. It is inserted by a large tendon (the tendo Achillis), common to this and the former muscle, into the lower and back part of the os calcis. 3. Plantaris, rises from the upper and posterior part of the outer condyle of the os femoris. It is inserted into the inside of the back part of the os calcis. 4. Popliteus rises from the outer condyle of the thigh. It is inserted into the upper and inner part of the tibia. 5. Flexor longus digitorum pedis, rises from the upper and inner part of the tibia. It is inserted into the last bone of all the toes, except the great toe. 6. Flexor longus pollicis pedis, rises from the back part, and a little below the head of the fibula. It is inserted into the last bone of the great toe. 7. Tibialis posticus rises from the back part and outer edge of the tibia, and from the interosseous ligament and adjacent part of the fibula. It is inserted into the inner and upper part of the os naviculare, and side of the os cuneiforme medium. 8. Peroneus longus, rises from the outer side of the head of the tibia, and from the upper anterior and outer part of the fibula. It is inserted into the metatarsal bone of the great toe. 9. Peroneus brevis, rises from the outer and forepart of the fibula. It is inserted into the metatarsal bone of the little toe. 10. Extensor longus digitorum pedis, rises from the upper, outer, and fore part of the tibia, interosseous ligament, and inner edge of the fibula. It is inserted into the first joint of the smaller toes. 11. Peroneus tertius, rises from the lower half of the fibula, and the interosseous ligament. It is inserted into the metatarsal bone of the little toe. 12. Tibialis anticus, rises from the upper and fore part of the tibia. It is inserted into the os cuneiforme internum. 13. Extensor proprius pollicis pedis, rises from the upper and fore part of the tibia. It is inserted into the convex surface of the bones of the great toe.

Muscles on the foot.

1. Extensor brevis digitorum pedis, rises from the upper and anterior part of the os calcis. It is inserted by four tendons; one joins the tendon of the externus longus pollicis, and the other three the tendons of the extensor digitorum longus. 2. Flexor brevis digitorum pedis, rises from the lower part of the os calcis. It is inserted into the second phalanx of each of the small toes. 3. Abductor pollicis pedis, rises from the inner and lower part of the os calcis. It is inserted into the first joint of the great toe. 4. Abductor minimi digiti, rises from the outer tubercle of the os calcis, the root of the metatarsal bone of the little toe, and also from the aponeurosis plantaris. It is inserted into the first joint of the little toe. 5. Lumbricalis pedis, rises from the tendons of the flexor longus digitorum pedis. It is inserted into the tendinous expansion, at the parting of the toes. 6 Flexor brevis pollicis pedis, rises from the inferior and anterior part of the os calcis, and the inferior part of the cuneiforme externum. It is inserted into the first joint of the great toe. 7. Adductor pollicis pedis rises from near the roots of the metatarsal bones of the second, third, and fourth toes. It is inserted into the first joint of the great toe. 8. Transversales pedis, rises from the outer and under part of the anterior end of the metatarsal bone of the little toe. It is inserted into the metatarsal bone of the great toe. 9. Flexor brevis minimi digiti pedis, rises from the basis of the metatarsal bone of the little toe. It is inserted into the first joint of the little toe. 10. Interossei pedis interni et externi, situated between the metatarsal bones.

SPLANCHNOLOGY explains the doctrine of the viscera. These are divided into thoracic, abdominal, and pelvic. The cavity of the thorax is divided into five lesser cavities, viz. the anterior cavity of the mediastinum, the posterior cavity of the mediastinum, the cavity of the pericardium, and the right and left cavities of the thorax.

Before describing the abdominal viscera, we may enumerate the salival glands, as they also are referable to the article splanchnology. They are the parotid, maxillary, sublingual, thyroid, molar, buccal, labial, lingual, amygdaline, palatine, uvular, arytenoid, &c. the names of most of which explain their situation.

The abdomen is divided into the epigastric, hypochondriac, umbilical, epicholic, hypogastric, and inguinal regions. Its contents are the peritoneum and its productions, the stomach, the intestines, the liver and gall-bladder, the spleen and pancreas, the kidneys, ureters, &c. The productions of the peritoneum are the great and small omentum and the mesentery, supporting and conveying the vessels to the intestines. The stomach consists of a great and small curvature, a great and small extremity, one orifice named cardiac, and another termed pylorus. The small intestines consist of the duodenum, and the ilium. The great intestines consist of the cæcum, which posesses an appendix, and has upon it the commencement of three ligamentary bands of the colon, externally appendices epiploicæ, and internally valvulæ conniventes forming the cells of the colon, and of the rectum terminating in the anus. The liver consists of two great lobes and a small one; it has a middle, right, left, and a round ligament; its internal structure is composed of the penecilli, or terminations of the venæ portæ, the pori biliarii, in which the bile is secreted, and the hepatic ducts, which terminate in one trunk, and convey the bile from the liver. The gall-bladder consists of a fundus, a body, and a neck, which terminates in the duct called cysticus, and this joining the hepatic, they form together the ductus communis choledocus. The spleen is not properly understood, either in its structure or uses. The pancreas resembles the salivary glands, and possesses a duct which terminates together with the ductus communis choledocus, in the duodenum. The kidneys are placed behind the peritoneum: their internal cavity is called pelvis, and opens into the ureter.

The pelvic viscera consist of the urinary bladder, and the organs of generation. The bladder consists of a bottom, a body, and a neck; its coats are a muscular, a cellular, and a villous. The male organs of generation consist of the testes, which have three coats, the tunica vaginalis, the cremaster, and the tunica

albuginea. The prostate gland is situated between the neck of the bladder and the bulb of the urethra; the projection on its inner surface is named caruncula. The penis itself consists of the corpora cavernosa on each side, the urethra inferiorly, the corpus spongiosum surrounding the former, the glans penis terminating the corpus spongiosum, and the integuments and preputium, which invests the whole. The female organs of generation consist of the pubes, or mons Veneris, the labia, the clitoris consisting of two crura and a body, the nymphæ internal to the labia, the urethra and the vagina, which, in virgins, contains the hymen or circulus membraneus, and its remains called carunculæ myrtiformes. The internal are the uterus and its appendages. The uterus consists of a neck, a body, and a fundus, and has a triangular cavity within it; its inferior aperture is called os tincæ. The ligamenta lata tie the uterus to the sides of the pelvis. The ovaria are fixed by the round ligaments to its corners, and the Fallopian tubes proceed from its fundus towards the sides of the pelvis.

ANGIOLOGY.

ANGIOLOGY, or the doctrine of the vessels of the body, (from αγγειον, a vessel, and λογος, a discourse) is divided into three parts, the first treats of the absorbents, the second of the arteries, and the third of the veins.

Of the absorbent system.

The absorbent system consists of the lacteals, the lymphatic vessels, their common trunk, the thoracic duct, and the glands called conglobate.

The lacteals begin from the intestinal tube, and can, for the most part, be seen in a dog, or other large quadruped, that is killed two or three hours after eating, when they appear filled with a white chyle.

The lymphatic vessels are small pellucid tubes that have now been discovered in most parts of the human body. The fluid they contain is generally as colourless as water; a circumstance which procured them at first the name of ductus aquosi, and afterwards that of vasa lymphatica.

All the lacteals, and most of the lymphatic vessels, open into the thoracic duct, which lies upon upon the spine, and runs up towards the neck, where it commonly opens into the angle between the internal jugular and subclavian veins of the left side: and thus both the chyle and the lymph are mixed with the blood.

The lacteals, the lymphatics, and the thoracic duct, all agree in having their coats thinner and more pelucid than those of the blood-vessels, but they are much stronger.

The coats of lymphatic vessels have, in common with all other parts of the body, arteries and veins for their nourishment.

The lymphatic system in most animals, but particularly in man and quadrupeds, is full of valves; and hence these lymphatics have sometimes been distinguished by the name of valvular lymphatic vessels. Those valves are generally two in number; are of a semilunar shape, and one is sometimes much larger than the other. In some parts of the body there are three or four pair in an inch of space; but sometimes there are several inches of a lymphatic without a valve. They are less numerous in the thoracic duct than in the branches of the system. When the vessels are distended with lymph, they appear larger on that side of the valves next the heart, which gives a lymphatic vessel an appearance of being made of a chain of vesicles.

The lymphatic system has the glands, called conglobate or lymphatic. These glands are so placed, that the vessels come in on one side, and pass out on the other, in their way to the thoracic duct. They are commonly of an oval, though sometimes of a round shape, and of various sizes; some being no larger than a millet seed, while others are almost an inch in diameter. They vary in colour in different parts of the body, and at different times of life.

The absorbent system, besides the glands, is divided into three parts, viz. the lacteal, the lymphatic vessels and the lacteal sac, and the lymphatic duct. The lacteals belong to the intestinal tube, the lymphatics to all the other parts of the body, and the lacteal sac and thoracic duct is the common trunk which receives both the lacteals and lymphatics.

Of the heart, lungs, and arterial system.

By the thorax we commonly understand all that part of the body which answers to the extent of the sternum, ribs, and vertebræ of the back, both outwardly and inwardly.

The thorax is divided into the anterior part, commonly called the breast; the posterior part called the back, and the lateral parts called the right and left sides.

Pleura and mediastinum.

The pleura is a membrane which adheres very closely to the inner surface of the ribs, sternum, and musculi intercostales, sub-costales, and sterno-costales, and to the convex side of the diaphragm. It is of a very firm texture, and is supplied with blood vessels and nerves, in all which it resembles the peritonæum.

Each side of the thorax has its pleura distinct from the other; and situated in such a manner as to form a double septum, or partition, running between the vertebræ and the sternum, their other sides adhering to the ribs and diaphragm.

This particular duplicature of the two pleuræ is termed mediastinum: the two laminæ of which it is made up are closely united together near the sternum and vertebræ; but in the middle, and toward the lower part of the fore side, they are separated by the pericardium and heart. A little more backward they are parted by the œsophagus; and, in the most posterior part, a triangular space is left between the vertebræ and the two pleuræ which is filled chiefly by the aorta.

Before the heart, from the pericardium to the sternum, the two laminæ adhere very closely, and there the mediastinum is transparent, except for a small space near the upper part, where the thymus gland is situated.

The thorax is divided into two cavities, entirely separated from each other by a middle septum, without any communication, and by the obliquity of this partition, the right cavity is greater than the left; but there are exceptions to this description.

The pleura is connected to the membranous

portion of the sternum, ribs, and muscles; to the diaphragm, pericardium, thymus gland, and vessels; and, in a word, to whatever lies near its convex side.

The pleura serves in general for an inner integument to the cavity of the thorax. The mediastinum cuts off all communication between the two cavities, and hinders one lung from pressing on the other when we lie on one side. It likewise forms receptacles for the heart, pericardium, œsophagus, &c.

Pericardium.

The heart, with all the parts belonging to it, is contained in a membranous capsula, called pericardium, which is, in some measure, of a conical figure, and somewhat bigger than the heart; but the difference must be less during life, when the heart is full of blood.

The pericardium is made up of three laminæ; the middle and chief of which is composed of very fine tendinous filaments; they are closely interwoven, and cross each other in different directions. The internal lamina seems to be a continuation of the outer coat of the heart, auricles, and great vessels. The trunks of the aorta and pulmonary artery have one common coat, which contains them both, and is lined on the inside by a cellular substance.

The pericardium is connected to the diaphragm exactly at that place which answers to the flat or lower side of the heart; and it is a very difficult matter to separate it from the diaphragm in dissection.

The external lamina, or common covering, is formed by the duplicature of the mediastinum.

The internal lamina is perforated by an infinite number of very small holes, through which a serous fluid continually transudes. This fluid being generally collected after death, makes what is called aqua pericardii, found in considerable quantities in opening dead bodies while they remain fresh.

Of the heart.

The heart is a muscular body, situated in the cavity of the thorax on the anterior part of the diaphragm between the two laminæ of the mediastinum. It is of a conical figure, flatted on the sides, round at the top, and oval at the basis. Accordingly we consider in the heart, the basis; the apex; two edges, the one right and the other left; and two sides, one of which is generally flat and inferior, the other more convex and superior.

Besides the muscular body, which forms what we chiefly call the heart, its basis is accompanied by two appendices called auriculæ, and by large blood-vessels; and all these are included in the pericardium.

The heart is hollow within, and divided by a septum into two cavities called ventriculæ, one of which is thick and solid, the other thin and soft.

Each ventricle opens by two orifices; one of which answers to the auricles, the other to the mouth of a large artery. The right ventricle opens into the right auricle, and the trunk of the pulmonary artery; the left into the left auricle, and into the great trunk of the aorta. At the edges of these orifices are found several valves, of which some are turned inward toward the cavity of the ventricles called the tricuspid; others are turned toward the great vessels, called semilunar, or sigmoid.

The inner surface of the ventricles is very uneven, many eminences and cavities being observable therein. The most considerable eminences are thick fleshy productions, called columnæ carniæ. To the extremities of these are fastened several chordæ tendidæ, tendinous cords, the other ends of which are joined to the valvulæ tricuspides.

The valves at the orifices of the ventricles are of two kinds; one kind allows the blood to enter the heart, and hinders it from going out the same way; the other kind allows the blood to go out of the heart, but hinders it from returning.

The auricles are two muscular bags, situated at the basis of the heart, and their capacities are in proportion to those of their respective ventricles; one toward the right ventricle, the other toward the left, and joined together by an inner septum, and external communicating fibres, much in the same manner with the ventricles; one of them being named the right auricle, the other the left.

The right auricle is larger than the left, and joins the right ventricle by a common tendinous opening.

It has two other openings united into one, and formed by two large veins which meet and terminate there almost in a direct line, called vena cava, superior and inferior.

Of the lungs.

The lungs are two large spongy bodies, of a reddish colour in children, greyish in adult subjects, and bluish in old age; filling the whole cavity of the thorax, one being seated in the right side, the other in the left, parted by the mediastinum and heart.

The right lung is generally larger than the left, answerable to the cavity of the breast, and to the obliquity of the mediastinum.

The substance of the lungs is almost all spongy, being made of an infinite number of membranous cells, and of different sorts of vessels spread among the cells in innumerable ramifications.

This whole mass is covered by a membrane continued from each pleura, which is commonly said to be double.

The vessels which compose part of the substance of the lungs are of three or four kinds; the principal of these are air vessels and blood-vessels. The air-vessels make the chief part, and are termed bronchia.

These bronchia are conical tubes, connected together by a ligamentary elastic membrane; and disposed in such a manner, that the lower easily insinuate themselves within those above them.

The bronchia are divided into an infinite number of ramifications, which diminish gradually in size, and change their cartilaginous structure into that of a membrane.

Each of these bronchial tubes is widened at the extremity, and formed into a cell called a vesicle. These cells are closely connected together in bundles; each small branch producing a bundle proportionable to its extent, and the number of its ramifications.

The lobules appear to be parted by another cellular substance, which surrounds each of them in proportion to their extent, and fills up the interstices between them.

This substance is dispersed through every part of the lungs, and is afterwards spread over the outer surface of each lung, where it forms a kind of fine cellular coat.

All the bronchial cells are surrounded by a very fine reticular texture of the small extremities of arteries and veins, which communicate every way with each other.

The blood-vessels of the lungs are of two kinds; one common, called the pulmonary artery and veins; the other proper, called the bronchial arteries and veins.

The pulmonary artery goes out from the right ventricle of the heart; and as high as the curvature of the aorta, is divided into two lateral branches, one going to the right hand, the other to the left.

The pulmonary veins go out on each side by two great branches, which open laterally into the reservoir or muscular bag of the right auricle.

The ramifications of the arteries are larger and more numerous than those of the veins, which in all other parts of the body exceed the arteries both in number and size.

Besides the capital blood-vessels, there are others called the bronchial arteries and veins, which are very small, but they follow the bronchia through all their ramifications. They communicate with the pulmonary arteries and veins, likewise with the arteries and veins of the œsophagus, and with branches of the coronary artery and vein.

Under the root of each lung, there is a broad ligament, which ties the posterior edge of each lung to the lateral parts of the vertebræ of the back from the root all the way to the diaphragm.

The bronchia, already described, are branches or ramifications of a large canal, partly cartilaginous, and partly membranous, called trachea, or aspera arteria. It is situated anteriorly in the lower part of the neck, whence it runs down into the thorax between the two pleuræ through the upper space left between the duplicature of the mediastinum, behind the thymus.

Having reached as low as the curvature of the aorta, it divides into lateral parts, one toward the right hand, the other toward the left, which enter the lungs, and are distributed through them.

Of the arteries in general.

The arteries are long elastic and pulsating tubes, the diameters of which decrease according to the number of branches which they give off.

The coats of the arteries are three in number: an external or cellular coat, a middle or muscular coat, and an internal or smooth membranous coat.

The use of the arteries is to convey blood from the heart through the lungs, throughout the system in general, or the heart itself.

The aorta.

The large arteries, termed aorta, open with a wide orifice from the superior and posterior side of the left ventricle of the heart. Its roots seem incorporated with the very substance of the heart: as it is not only intimately united with its internal surface, but some muscular striæ of the ventricle are also mixed with the white line, which is called tendo-arteriosus, and which indicates the commencement of the artery. Some transverse fibres of the heart are united to the external part of the aorta, and cover it for a line and a half. Having left the heart, the aorta is immediately expanded; nor does it again recover its diameter till it sends off the subclavian artery of the right side.

In its ascent, it is first inflected to the right, behind and beyond the pulmonary artery; it gradually inclines itself to the left, till, having formed a transverse arch, it is seen projecting behind the lungs at the left side of the vertebræ. Supported by these it descends in the same straight line with themselves: till, having, at last, entered the abdomen, it again begins to turn toward the right, and rests upon the middle of the vertebræ.

The two coronary arteries of the heart arise from beneath the semilunar valves, and form, in returning to the heart, an acute angle with the rising trunk.

From the arch of the aorta rise also the subclavian and carotid arteries. The right subclavian and carotid in one trunk, but the left is single.

The carotid arteries run along each side of the larynx to the sixth foramen of the skull, where they enter and proceed to the brain. In their passage thither, they give out numerous branches, which are named from the parts to which they go, as laryngæ, thyroidæ, linguales, temporales, &c. These also send out each a small branch through the fifth foramen to that part of the dura mater which contains the cerebrum.

The internal carotids send two branches to the posterior part of the nose, and some others through the first and second foramen of the skull, to the face and the parts within the orbits of the eyes; and after perforating the internal surface of the dura mater, divide each into two distinct branches, one passing between the two hemispheres of the brain, and the other between the anterior and posterior lobes.

These branches assume a variety of directions, and divide into numerous small branches in the pia mater before they reach the brain. There are two other arteries belonging to the brain named cervicales, which have their origin in the subclavian arteries, and rise to the head through the foramina. These send branches to the cerebellum, after which they divide and communicate with the carotids.

Each of the subclavian arteries is continued to the cubit in one trunk, this is called axillaris, as it passes the armpits, and humeralis, as it passes the os humeri. From the subclavian within the breast the arteriæ mammariæ arise, which run along the inside of the sternum. The arteria humeralis, near the joint of the cubit divides into two branches, named the cubitalis superior and inferior; the latter soon sends off another, called cubitalis media. The two first give branches to the hands and fingers, and the last to the muscles about the elbow.

From each side of the descending aorta, a branch is sent under each rib, which is termed intercostalis, and towards the fourth vertebra of the back, it sends two branches to the lungs, which are termed bronchiales. Where this aorta passes under the diaphragm it sends

to it two branches called arteriæ phrenicæ. Below the diaphragm, rises the cæliac artery from the aorta. This divides into several branches, passing to the liver, the pancreas, the stomach, and duodenum, which are named from the parts on which they are bestowed.

Just below the cæliac artery, from the aorta, rises the mesenteric, which is the largest of the ventral branches. The branches of this artery are distributed upon the intestinum, jejunum, and ilium, part of the colon, and sometimes on the liver.

A little below this, the emulgents, or arteries of the kidneys arise; and below these, and anterior to the aorta, arise the spermatic arteries which in the male subject are distributed to the genitals.

Laterally, and a little below the aorta, sends out branches to the loins; these are called lumbales; also one which goes to the colon and rectum, called the inferior mesentery.

Between the cæliac and two mesenteric arteries, and their branches near the intestines, are situated large branches to convey the blood from one to the other when they are compressed.

When the aorta divides on the loins, it sends an artery to the pelvis, on the os sacrum, which arteria sacra; the branches into which the aorta divides, are called iliacæ.

These are the internal and external. From the first proceed the umbilical arteries; the other branches are bestowed on the glutæi muscles, and on the upper part of the thighs.

The iliacæ external run over the ossa pubis into the thighs, and in their passages out of the abdomen, they send out the branches called epigastricæ, to the integuments under the recti muscles. Each of the epigastric arteries sends a branch into the pelvis, and through the foramina of the ossa inominata, to the muscles in that part.

The iliac artery having passed out of the abdomen into the groin is named inguinalis, and in the thigh it is called cruralis. Here it sends a branch to the back part of the thigh, and having passed through the insertion of the triceps into the ham, it takes the name of popliteal artery. It divides into two branches, one called tibialis anticus, which passes between the tibia and fibula down the fore part of the leg, and is bestowed on the great toe, and another between them to communicate with the tibialis postica: this artery sends off the tibialis media which is bestowed on the muscles of the leg.

The tibialis posticus proceeds to the bottom of the foot and lesser toes: the antica is disposed after the manner of the cubitalis superior: and the postica like the cubitalis inferior.

Of the veins.

Veins are membranous canals, which terminate either in the vena cava superior, vena cava inferior, or vena portæ. Like the arteries, they consist of three tunics, but have no pulsation, collapse when divided, possess a greater diameter than the arteries, have more numerous branches, a more reticular arrangement, and run more superficially. Except the veins of the viscera and brain, these vessels also possess valves.

The veins of the external part of the head and neck are the frontal, angular temporal, auricular, lingual, occipital, and muscular. All these terminate in the external jugular, which opens into the subclavian. The veins or sinuses of the brain, viz. the cavernous, circular, petrosal, occipital, longitudinal, superior, and inferior, the torcular, herophili, and the lateral, terminate in the internal jugular. The vertebral veins returning from the brain, terminate in a similar manner.

The chief veins of the other extremities are the axillary in the axilla, the brachial in the arm, and the cephalic on the outside, the median on the middle, and the basilic on the inside of the fore arm. The cephalic and basilic veins being joined by the mediana cephalica and mediana basilica, pass up the arm.

The veins of the thorax are the interna thoracic veins, the vena azygos, and the two subclavian.

The vena portæ, distributed through the liver, derives its blood from the mesenteric and splenic veins.

Those of the loins and pelvis exactly correspond to the lumbar and pelvic arteries.

The veins of the lower extremities are the vena saphena major, which passes up the inside of the leg and thigh, and terminates in the groin; the vena saphena minor, which passes up the outside of the leg, and terminates in the ham; the popliteal and the crural veins, which accompany their corresponding arteries.

It must be observed, that both in the leg and in the thigh, each deep-seated artery is accompanied by two corresponding veins, denominated vena sodales.

Of the eye.

The principal and most essential part in each organ, is the globe or ball of the eye; the others are partly external and partly internal. The external parts are the supercilia, or eye-brows, the palpebræ, or eye-lids, the caruncula lachrymalis, and the puncta lachrymalia; and the internal parts are the muscles, fat, lachrymal gland nerves and blood-vessels

The globe or ball of the eye

The globe of the eye being the most essential of all the soft parts belonging to the organ of sight, must be first described. It is made up of several parts; some of which being more or less solid, represent a kind of shell formed by the union of several membranous strata, called the coats of the globe of the eye; the other parts being more or less fluid, and contained in particular membranous capsulæ, are termed the humours of the globe of the eye. The coats of the globe of the eye are of three kinds. Some form chiefly the shell of the globe; some are additional, being fixed only to a part of the globe; and some are capsular, which contain the humours. The coats, which form the globe of the eye, are, the sclerotic, to which the convexity of the globe is owing; the cornea, which forms the anterior part of the globe; the iris, or circle, surrounding the pupil, choroides, and retina, or expansion of the optic nerve. The additional is the conjunctiva, which covers the whole fore part of the eye, and lines the eye-lids. The capsular tunicæ are two, the vitreæ and cystallina.

The globe of the eye receives from behind a pedicle, which is the continuation of the optic

nerve. It is situated about the middle of the orbit; and it is tied to it by the optic nerve, by six muscles, by the tunica conjunctiva, and by the palpebræ. The back part of the globe, the optic nerve, and muscles are surrounded by a soft, fatty substance, which fills the rest of the bottom of the orbit. The humours are three: the aqueous, vitreous, and crystalline. The first is contained in a space formed in the interstices of the anterior portion of the coats. The second is contained in a particular membranous capsula, and fills above three-fourths of the shell or cavity of the globe of the eye. It has been named vitreous, from its supposed resemblance to melted glass; but is really more like the white of a new-laid egg. The crystalline humour is so called from its resemblance to crystal.

The external parts of the eye.

The supercilia, or eye-brows, are the two ridges covered with hair, situated at the lower part of the forehead, between the top of the nose and temples.

The palpebræ are a kind of veils placed above and below the anterior portion of the globe of the eye. The superior is the largest and most moveable in man.

The tarsi are thin cartilages forming the principal part of the edge of each palpebra; and they are broader at the middle than at the extremities. The ligaments of the tarsi are formed by the union of the periosteum of the orbits, and pericranium along both edges of each orbit. The lacrymal gland, is yellowish, and of the number of those called conglomerate glands. From this gland several small ducts go out, which run down through the substance of the tunica interna, and afterwards pierce it inwardly near the superior edge of the tarsus.

The flat edge of each palpebra is adorned with a row of hairs, called cilia, or the eye-lashes.

Along the same border of the palpebræ, toward the eye, we see a row of small holes, which may be named puncta ciliaria. They are the orifices of small oblong glands which lie in the sulci, channels, on the inner surface of the tarsus. Near the great and internal angle of the palpebræ lacrymales, ductus, two small holes are very visible, commonly named puncta lacrymalia, being the orifices of two small ducts called lacrymal, which unite beyond the angle of the eye, and open a little below the upper end of a particular reservoir, termed sacculus lacrymalis. The caruncula lacrymalis is a small reddish, granulated, oblong body, situated between the internal angle of the palpebræ and globe of the eye.

Of the ear.

Two portions are distinguished in the external ear; one large and solid, called pinna, which is the superior, more cartilaginous, and by much the greater part; the other small and soft, called the lobe, which makes the lower part.

The fore side is divided into eminences and cavities. The eminences are four, called helix antihelix, tragus, and antitragus. The helix is the large border, or circumference of the great portion of the ear. The antihelix is the oblong eminence, surrounded by the helix. The tragus is the small anterior protuberance below the extremity of the helix. The antitragus is the posterior tubercle, below the inferior extremity of the antihelix.

The cavities on the fore side are four; the hollow of the helix, the depression at the extremity of the antihelix, the conchæ, or great double cavity; and lastly, the meatus of the external ear, situated at the lower part of the bottom of the concha.

The bony part of the organ of hearing may be divided into four parts. 1. The meatus auditorius externus. 2. The tympanum. 3. The labyrinth. 4. The meatus auditorius internus. It may likewise be divided into immoveable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called incus, malleus, stapes, and os obiculare or lenticulare.

The meatus externus is somewhat more than half an inch in length, running in a curved direction. It terminates inwardly by an even circular edge.

The tympanum, or drum of the ear, is a cavity somewhat hemispherical, the bottom of which is turned inward. The remarkable eminences are three; a large tuberosity, lying in the very bottom of the tympanum, a little toward the back part, and a small irregular pyramid situated above the tuberosity, and a little more backward, the apex of which is perforated by a small hole. In the third eminence is a cavity situated at the upper end a little toward the anterior part of the bottom of the tympanum.

The principal cavities in the tympanum are the opening of the mastoid cells, the opening of the Eustachian tube, the bony half-canal, the fenestra ovalis and rotunda; and the small hole in the pyramid.

The labyrinth is divided into three parts; the anterior, middle, and posterior; the middle portion is termed vestibulum, the anterior cochlea, and the posterior labyrinth in particular, which comprehends the three semicircular canals.

The cochlea lies forward and inward, toward the extremity of the pars petrosa; the semicircular canals backward and outward, toward the basis of the process, and the vestibulum between the other two.

The meatus auditorius internus is on the back side of the pars petrosa, in some measure behind the vestibule and basis of the cochlea fossulæ; one large and the other small.

The Eustachian tube, is a canal, which goes from the tympanum to the posterior openings of the nares, and towards the arch of the palate.

The membrana tympani is a thin, transparent, flattish pellicle, the edge of which is round, and strongly fixed in the orbicular groove which divides the bony meatus of the external ear from the tympanum, or barrel. The whole internal cavity of the labyrinth is filled with a watery fluid, secreted from the vessels, which are dispersed upon the periosteum. This fluid transmits to the nerves the vibrations it receives from the membrane situated between the tympanum and labyrinth.

The portio mollis of the auditory nerve ends, by its trunk, at the great fossula of the internal auditory hole, whence the filaments pass through the cochlea, the vestibule, and the semicircular canals, upon membranous canals, and bags disposed within them.

Of the nose and the sense of smelling.

The cavity of the nose is divided into parts called the nostrils, by a partition of which the upper part is bony, and the lower cartilaginous. The upper part of the cavity is covered with a thick glandulous membrane, above which the olfactory nerve is finely branched out, and spread over the membrane of the spongy bones of the nose, and other sinuous cavities of the nostrils. The odorous effluvia of bodies being disseminated in the atmosphere, the latter fluid passes through the nose in respiration, and the odorous particles are thus brought into contact with the fibres of the nerves, which, by their communication with the brain, excite in the mind the sense of smell.

Of the mouth, and organ of taste.

The bony parts of the mouth are the ossa maxillaria, ossa palati, maxilla inferior, and the teeth; to these we may add os hyoides, and the upper vertebræ of the neck.

The external parts of the mouth require no description.

The internal parts of the mouth are, the gums, palate, septum palati, uvula, amygdalæ, the tongue, the membrane which lines the whole cavity, the salival ducts and glands, and the bottom of the mouth.

The palate is that arch of the mouth, surrounded anteriorly by the alveolar edge and teeth of the upper jaw, and reaching thence to the great opening of the pharynx. The arch is partly solid and immoveable, and partly soft and moveable.

The velum palati terminates below by a loose floating edge, representing an arch, situated transversely above the basis, or root, of the tongue. The highest portion of this arch sustains a small, soft, and irregularly conical glandular body, fixed to the arch, and its apex hanging down, without adhering to any thing, which is called uvula. On each side of the uvula there are two muscular half arches, called columnæ septi palati, which contain between them the glands called amygdalæ.

The tongue is divided into the basis and point, the upper and under sides, and the lateral portions or edges. The papillæ with which the tongue is covered are composed of the extremities of the nerves of that member, and piercing the external membrane, are constantly affected by those qualities in bodies which have their tastes excited in the mind by means of these nervous papillæ, which are the immediate organ of tasting. This organ bears a considerable resemblance to the sense of touch.

Of the skin and organ of touch.

The common integuments are divided into cuticula, rete, mucosum, cutis vera, and corpus adiposum.

The skin is covered by a thin transparent pellicle, closely joined to it, called epidermis, cuticula, or scarf-skin.

Under the cuticle, we meet with a substance of a greyish colour, which has the name of corpus cuticulare, or rete mucosum; it is of a soft, mucilaginous, and viscid nature, and fills up the interstices of the fibres running between the cutis vera and cuticula. After raising the cuticle in a negro, where it is thickest and most distinct, this substance appears of a black colour, and is composed of two layers. It is this that chiefly gives the colour to the skin, for it is black in the African, and white, brown, or yellowish, in the European.

The cutis vera, or skin, is made up of several kinds of fibres, closely connected together, and running in various directions, being composed of the extremities of numerous vessels and nerves.

In different parts of the body, we meet with small glands, or follicles, of an oval form, and seated chiefly under the skin in the corpus adiposum. These are called sebaceous and miliary.

The last universal integument of the human body is the membrana adiposa, or corpus adiposum.

The nails are productions of the epidermis.

The hairs belong as much to the integuments as the nails. Their roots, or bulbs, lie toward that side of the skin which is next the membrana adiposa.

The papillæ of the fingers may become erect or elevated, and being gently pressed against a tangible body, receive an impression which is conveyed to the brain, and is called touch.

Of the brain

This mass is divided into three particular portions: the cerebrum, or brain, properly so called, the cerebellum, and medulla oblongata. To these three parts, a fourth is added, which fills the great canal of the spina dorsi, by the name of medulla spinalis, being a continuation of the medulla oblongata.

The meninges, or membranes of the brain, are two; one of which lies contiguous to the cranium; the other immediately touches the brain. The first is named dura mater, the second pia mater.

The Cerebrum.

The cerebrum, is a kind of medullary mass, of a greyish colour, filling all the superior portion of the cavity of the cranium. The cerebrum is divided into two lateral portions, separated by the falx, or great longitudinal septum of the dura mater. They are generally termed hemispheres, but they are more like quarters of an oblong spheroid. Each of these portions is divided into two extremities, which are termed the lobes of the cerebrum, between which there is a large inferior protuberance, which goes by the same name.

Each lateral portion of the cerebrum has three sides; one superior, one inferior, and one lateral. Through the whole surface there are inequalities, or windings, like the circumvolutions of intestines, very deep and narrow, into which the septa, or duplicates of the pia mater, insinuate themselves.

Substance.—The substance of the cerebrum is of two kinds, distinguished by two different colours, one part of it being of a greyish or ash colour, the other, remarkably white. The ash-coloured substance lies chiefly on the outer part of the cerebrum, like a kind of cortex, whence it has been named substantia corticalis, or cinerea. The white substance occupies the inner part, and is termed substantia medullaris or substantia alia.

Between the two hemispheres of the cerebrum, and below the circumvolutions, is found

a white convex body called corpus callosum; and under this are the two lateral or superior ventricles of the brain; these are divided into right and left by a membrane called septum lucidum.

The septum lucidum is united by its lower part, to the anterior portion of the medullary body, called the fornix. It is in reality nothing but the corpus callosum; the lower side of which is like a hollow ceiling, with three angles, one anterior, and two posterior, and three edges, two lateral and one posterior.

Under the fornix, and immediately behind its anterior crura, there is a hole, the foramen Monroi, of a considerable size, by which the two lateral ventricles communicate, and another passage leads down from this, under the different appellations of foramen commune anterius, vulva, iter ad infundibulum, but more properly iter ad tertium ventriculum. Although this is denied by some writers on anatomy, who affirm that it is shut up at the bottom by the pia mater.

The fornix being cut off, we see first of all a vascular web, called plexus choroides, and several eminences more or less covered by the expansion of that plexus. There are four pairs of eminences, two large, and two small. The first two great eminences are named corpora striata, and the second thalami nervorum opticorum. The four small eminences are closely united together; the anterior being called nates, and the posterior testes; but it would be better to call them simply anterior and posterior tubercles. Immediately before these tubercles, there is a single eminence called glandula pinealis, or pineal gland, which Des Cartes supposed to be the seat of the soul.

The plexus choroides is a very fine vascular texture, consisting of a great number of arterial and venal ramifications, partly collected in two loose vasculi, and partly expanded over the neighbouring parts, and covering the thalami nervorum opticorum, glandula pinealis, tubercula quadrigemina, and the other adjacent parts, both of the cerebrum and cerebellum, to all which it adheres.

The Cerebellum.

The cerebellum is contained under the transverse septum of the dura mater, in the under and back part of the cranium.

It is made up like the cerebrum, of two substances. It has two middle eminences, called appendices vermiformes: one anterior and superior, and turned forward; the other posterior and inferior, which goes backward.

When we separate the two lateral portions or lobes, we discover first of all the posterior portion of the medulla oblongata; and in the posterior surface of this portion, we observe an oblong cavity, which is called the fourth ventricle; this terminates backward, like the point of a writing pen. Hence the under end of it is called calamus scriptorius. If we cut one lobe of the cerebellum vertically, from above downward, the medullary substance will appear to be dispersed in ramifications, through the cortical substance. These ramifications have been named abor vitæ, and the two trunks, whence these different laminæ arise, are called pedunculi cerebelli.

Medulla oblongata

The medulla oblongata is a medullary substance, situated from before backward in the middle part of the basis of the cerebrum and cerebellum, without any discontinuation between the lateral parts of both these bases.

Medulla spinalis.

The medulla spinalis is only an elongation of the extremity of the medulla oblongata, and has its name from being contained in the bony canal of the spina dorsi.

It is worthy of observation that the characteristics of the three substances just mentioned appear in this, viz. that wounds in the cerebrum, though, in most cases very dangerous, are not mortal; but in the cerebellum, and medulla oblongata, they cause instant death; and in the spinal marrow, they occasion loss of sense in all the parts which receive nerves from below the wounds.

Of the Nerves.

In several places we can observe the medulla to be composed of fibres laid at each other's sides; and it is employed in forming the white fibrous cords, which have now the name of nerves appropriated to them. Within the skull, we see the nerves to be the medullary substance continued, and the spinal marrow is employed in forming all nerves.

How small one of these fibres of the nerve is, we know not; but when we consider that every, even the most minute part of the body is sensible, and that this must depend upon the nerves, (which, all conjoined, would not make a cord of an inch diameter) being divided into branches or filaments, to be dispersed through all these minute parts, we must be convinced that the nervous fibrils are very small.

Nerves are generally lodged in a cellular or fatty substance, and have their course in the interstices of muscles and other active organs, where they are guarded from pressure; but in several parts they are so placed, as if it was intended that they should there suffer the vibrating force of arteries, or the pressure of the contracting fibres of muscles.

The larger cords of the nerves divide into branches as they go off to the different parts; the branches being smaller than the trunk from which they come. Where the nerves separate, they generally make an acute angle.

In several places different nerves unite into one cord, which is commonly larger than any of the nerves which form it. Several nerves, after such union, suddenly form a hard knot, considerably larger than all the nerves of which it is made. These knots are generally named ganglions.

It is generally said, that there are forty pair of nerves in all · of which ten come out from the encephalon, and the other thirty have their origin from the spinal marrow.

Of the ten pair of nerves which come from the encephalon, the first is the olfactory, which long had the name of the mamillary processes of the brain, because in the brutes, cows and sheep, which were more commonly dissected by the ancients, the anterior ventricles of the brain are extended forward upon these nerves, and adhere so firmly to them, that they seem to make the upper side of the nerves.

The second pair of nerves, the optic, rising from the thalami nervorum opticorum, make a large curve outward, and then run obliquely inward and forward, till they unite at the fore-part of the cella tunica; these soon divide, and each runs forward and outward, to go out at its proper hole in the sphenoid bone, to be extended to the globe of the eye, within which each is expanded into the retina.

The third rise from the anterior part of the processus annularis; and piercing the dura mater a little before, run along the receptacula to get out at the foramina lacera; after which each of them divides into branches, of which one, after forming a little ganglion, is distributed to the globe of the eye; the others are sent to the muscular rectus of the palpebra, and to the attollens, adductor, deprimens, and obliquus minor, muscles of the eye-ball.

The fourth pair, derive their origin from the back part of the base of the testes; and then making a long course on the side of the annular protuberance, enter the dura mater a little further back, and more externally, than the third pair, to run also along the receptacula, to pass out at the foramina lacera, and to be entirely spent on the musculi trochleares, or superior muscles of the eyes.

The fifth pair are large nerves, rising from the annular processes, where the medullary processes of the cerebellum join in the formation of that tube to enter the dura mater; and then each becomes in appearance thicker, forms a distinct ganglion, and goes out of the skull in three great branches.

The first branch runs through the foramen lacerum to the orbit. It is afterward distributed to the ball of the eye with the third; and to the nose, with the olfactory. This ophthalmic branch likewise supplies the parts at the internal canthus of the orbit, the glandula lachrymalis, fat, membranes, muscles, and teguments, of the eye-lids.

The second branch called maxillaris superior, from its serving principally the parts of the upper jaw, goes out at the round hole of the sphenoid bone, and sends immediately one branch into the channel on the top of the antrum maxillare; the membrane of which, and the upper teeth, are supplied by it in its passage.

The sixth pair rise from the fore part of the corpora pyramidalia, and having passed through the dura mater, send off a branch, which, with the ophthalmia branch of the fifth pair, forms the beginning of the intercostal nerve; after which it passes through the foramen lacerum to be spent on the musculus abductor oculi.

The seventh pair rises from the lateral part of the annular process, and enters the internal meatus auditorius, where it divides into two parts, one of which is stretched on the inner camera of the ear, and the other passing through the fallopian aqueduct, comes out on the skull. The former is called portio mollis, the latter dura. This supplies the neck and other parts.

The eighth pair of nerves, named par vagum, from the number of parts to which it gives branches both in the thorax and abdomen, rises from the base of the corpora olivaria, in disgregated fibres, and at the aperture belonging to the ossa temporum and occipitis, this pair of nerves is then joined by the accessores Willisii, with which they pass out at the common foramen already mentioned. After this the accessorius separates, and is lost in the musculus trapezius and rhomboides scapula; whilst the great trunk runs down the neck near the carotid artery, and, on its entering the thorax, divides into two parts, the one supplying the pericardium, after which it is lost in the larynx; the other supplying the lungs, the gula, and stomach.

The ninth pair of nerves rise from the inferior part of the corpora pyramidalia, and go through the os occipitis, and are finally lost on the tongue.

The tenth pair rise in separate threads from the sides of the spinal marrow. After each of them has given branches to the great ganglion; it is distributed to the straight, oblique, and extensor muscles of the head.

The spinal nerves rise generally by a number of disgregated fibres from both the fore and back part of the medulla spinalis; and soon after form a little knot or ganglion, where they acquire strong coats, and are extended into firm cords: but the ganglion is entirely formed by the posterior bundle. There are generally said to be thirty pairs of them; seven of which come out between the vertebræ of the neck, twelve between those of the back, five between those of the loins, and six from the false vertebræ.

EXPLANATION OF THE ANATOMICAL PLATES.

Plate II.

A front view of the Skeleton.

1. The cranium.
2. The os frontis.
3, 3. The orbits.
4. Upper jaw-bone.
5. Teeth.
6. Lower jaw-bone.
7. The seven true ribs.
8. The five false ribs.
9. The first bone of the sternum.
10. The second bone of the sternum.
11. Ensiform cartilage.
12. The five lumbar vertebræ.
13. Ilium, or haunch bone.
14. Os ischii.
15. Os pubis.
16. Os sacrum, or bone of the rump.
17. Symphisis pubis.
18. Thigh-bone.
19. Head of the thigh-bone.
20. Trochanter major.
21. Patella, or knee-pan.
22, 23. External and internal condyles of the thigh.
24. Tibia,
25. Fibula.
26. Bones of the tarsus.
27. Bones of the metatarsus
28. Bones of the toes.
a. The clavicle, or collar-bone.
b. Scapula, or shoulder-blade.
c. Humerus, or bone of the arm.
d. Ulna.
e. Radius.
f. First row, or phalanx of carpal bones.
g. Second row, or phalanx of carpal bones.
h. Bones of the metacarpus.
i. First phalanges of the fingers.

k. Second phalanges of the fingers
l. Third phalanges.
m. Three phalanges of the thumb

PLATE III.

A back view of the Skeleton.

1, 2. Ossa parietalia.
3. Occipitis.
4. Os temporis.
5. Mastoid process of the temporal bone.
6. The seven cervical vertebræ.
7. The twelve dorsal vertebræ.
8. The five lumbar vertebræ.
11. Os sacrum, or rump-bone.
12. Os coccygis, or crupper bone
13. Ilium.
9. Ischium.
14. Neck of the thigh bone.
15. Trochanter major.
16. Trochanter minor.
17. Condyles of the thigh
18. Malleolus externus.
19. Malleolus internus.
20. Os calcis.

ANCHOR, in maritime affairs, is a very large and heavy iron instrument, with a double hook at one end, and a ring at the other, by which it is fastened to a cable. It is cast into the bottom of the sea, or rivers, where, taking its hold, it keeps ships from being drawn away by the wind, tide, or currents. The kinds of anchor in common use are the sheet anchor, the largest, which is only used in storms; the two bowers, made for ships to ride in harbours; the stream anchor; the grapple. To which we may add the newly invented anchor with one fluke by Mr. Stuard; and the new mooring anchor described by Mr. Hemman of Chatham; and for which he obtained the silver medal in 1809 from the Society for the Encouragement of Arts, &c.

ANCHORAGE, or ANCHORING-GROUND, a place where a ship may cast anchor.

The best anchoring-ground is stiff clay or hard sand; and the best place for riding at anchor, is where a ship is land-locked, and out of the tide.

ANCHOVY, in ichthyology and commerce, a species of clupea, with the upper jaw longest. See CLUPEA.

The anchovy is so like the common sprat, another species of clupea, that it is no wonder this fish is often pickled and sold under its name.

ANCHUSA, ALCANET or BUGLOSS; a genus of the monogynia order, belonging to the pentandria class of plants. The calyx is a quinquepartite perianthium, oblong and persistent; the corolla is monopetalous and funnel shaped, the throat closed with scales; the stamina consist of five short filaments; the antheræ oblong and covered; the pistillum has four germina, a filiform stylus, and obtuse stigma: there is no pericarpium, the calyx containing the seeds in its bosom: the seeds are four, oblong, gibbous, and engraven at the base. There are eight species, all of which may be propagated by seeds.

ANCISTRUM, a genus of the *diandria monogynia* class and order, and of the natural order of *rosaceæ*. The essential character is, cal. four-leaved, cor. none; stigma, many parted: drupe, dry, hispid, one-celled.

There are three species, but scarcely deserving notice

ANDALUSITE, or HARDSPAR, in mineralogy, a species of the felspar family, discovered by Bournon, in a primitive granitic mountain in Forez. Colour, flesh red, sometimes approaching to rose red. Massive, and crystallized, in rectangular four-side prisms. Specific gravity 3.16. Infusible by the blowpipe without addition. It is distinguished from felspar by its great hardness, and higher specific gravity, and from corundum, by its inferior specific gravity and its form. It is now found in the primitive mountains in Spain and France, with quartz and mica, and sometimes in a mica state at Braunsdorf, near Freyberg, in Saxony.

ANDRACHNE, in botany, a genus of the monoecia gynandria class of plants; the corolla of the male flower is formed of five emarginated slender petals, shorter than the cup; the female flower has no corolla; the fruit is a capsule containing three cells, with two obtuse trigonal seeds, roundish on one side, and angular on the other. There are three species.

ANDROGYNA, in botany, are plants which bear male and female flowers, with stamens only, and some with pistils only on the same root: such are the cucumber and melon.

ANDROIDES, in mechanics, is a term used to denote an automaton, in the figure of a man, which, by means of certain springs, levers, &c. duly contrived, walks and performs other external functions of a man. The most celebrated of these that have been exhibited in modern times were, the flute-player of Vaucanson, constructed and exhibited at Paris; the chess-player of M. de Kempelin of Presburg; and the chess-player lately exhibited in London The principle on which these ingenious pieces of mechanism produce their effects has hitherto remained a secret.

ANDROMEDA, in astronomy, a small northern constellation consisting of 63 stars, 27 of which are visible to the naked eye.

ANDROMEDA, in botany, a genus of the decandria monogynia class of plants; the calyx of which is a very small acute coloured and permanent perianthium, cut into five segments; the corolla consists of a single petal, of an oval form, inflated and quinquefid; the fruit is a roundish capsule, containing five cells, in which are several roundish shining seeds. There are 25 species.

ANDROPOGON, in botany, a genus of the polygamia monoecia class of plants, the calyx of which is a bivalve oblong, obtuse glume; the corolla is also a bivalve glume, smaller and thinner than the cup; there is no pericarpium; the seed, which is single, oblong, covered and armed with the arista of the flower, is included in the glumes of the calyx and corolla. There are 32 species.

ANEMOMETER, an instrument used for measuring the strength of the wind.

ANEMONE, WIND-FLOWER: a genus of the polygamia order, belonging to the polyandria class of plants; and in the natural method ranking under the twenty-sixth order, multisiliquæ. It has its name from the Greek, *ανεμος*, signifying the wind; because the flower is supposed not to open unless the wind blows.

There are 25 species of the anemone: the

double ones are propagated by offsets; and all the sorts are considered as among the finest ornaments of our gardens.

ANEMOSCOPE, a machine shewing from what point of the compass the wind blows.

This is done by means of an index moving about an upright circular plate, the index being turned by an horizontal axis, and the axis by an upright staff, at the top of which is the vane moved about by the wind.

ANETHUM,* *Dill*, in botany, a genus of umbelliferous plants of the digynia order, and pentandria class. The fruit is oval, compressed, striated: petals five, involute, entire, and short. There are three species, 1. *Anethum feniculum*, or fennel, of which there are two varieties, the common and the sweet; both cultivated in gardens; the common is a perennial plant; but the sweet fennel dies after it has produced seed. 2. *Anethum graveolens*, or *dill*, which is an annual plant. 3. *Finochio*, a sallad herb. The seeds and roots of the first kind are used in medicine.

ANGEL, a term which properly signifies *messenger*, and is used to designate those spiritual beings who are employed as the medium through which the Divine Being carries on the government of the universe.

It is also applied in Scripture to human beings who have been employed in any remarkable manner in executing the Divine will upon earth.

ANGEL, in commerce, the name of an ancient gold coin in England, of which some are still to be seen in the cabinets of the curious. It had its name from the figure of an angel, represented upon it. It was 23¾ carats fine, and weighed four pennyweights. Its value differed in different reigns.

ANGELICA, a genus of the digynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The essential characters are: the fruit is roundish, angled, solid, with reflecting styli; the corollæ are equal, and the petals incurvated. There are six species. The angelica arch-angelica, sativa, or common angelica, which is cultivated in gardens for medicinal use, and likewise for a sweetmeat, grows naturally in the northern countries. The root, which is the most efficacious part, is used in the aromatic tincture; and the stalks make an agreeable sweetmeat.

ANGIOSPERMIA, in the Linnæan system of botany, denotes those plants of the didynamia class, which have their seeds inclosed in a capsule, or seed-vessel.

ANGLE, in geometry, the inclination of two lines meeting one another in a point, and called the legs of the angle. See GEOMETRY.

ANGLING, among sportsmen, the art of fishing with a rod, to which are fitted a line, hook, and bait.

In angling the following rules are to be observed. 1. To place yourself so that your shadow does not at any time lie upon the water, if shallow. 2. To angle in a pond near the ford where the cattle go to drink; and in rivers, in such places as the fish you intend to angle for, usually frequent; as for breams, in the deepest water; for eels, under banks; for chub, in deep shaded holes; for perch, in scours; for roach, in the same places; for trouts, in quick streams.

The best times for angling are from April to October; for in cold stormy weather, or bleak easterly winds, the fish will not bite. The time of the day, in the warm months, is in the morning, about nine o'clock, and in the afternoon, between three and five. In order to attract the fish to the place intended for angling, it will be proper, once in four or five days to cast in some corn boiled soft, garbage, worms chopt to pieces, or grains steeped in blood, and dried; and if you fish in a stream, it will be best to cast in the grains above the hook.

The best way of angling with the fly, is down the river; and in order to make them rise freely, be sure to use such flies as you know they are naturally inclined to, and in such manner as they are accustomed to receive them.

ANGURIA, in botany, a genus of the monoecia diandria class and order: calyx five-cleft: corolla five-petalled: pome inferior, two-celled, many-seeded.

ANGUIS, in zoology, the name of a genus of serpents, distinguished from the rest by having the belly and under part of the tail covered with scales, like those on the other parts of the body. The body is shorter, and more uniformly cylindric, than in the genus of the coluber, and the eyes are in general small, and the tail rather obtuse. No poisonous species of anguis has yet been discovered. Gmelin enumerates 26 species of the anguis.

ANIMAL, in natural history, an organized and living body, which is also endowed with sensation: thus, minerals are said to grow or increase, plants to grow and live, but animals alone to have sensation.

The description, history, and classing of animals, makes not only a considerable, but the most excellent part of natural history, known by the name of zoology. Different authors have established different divisions or families of animals; but the most natural one seems to be into quadrupeds, birds, fishes, amphibious animals, insects, and animalcules, visible only by the help of a microscope.

ANIMALCULE, an animal so minute in its size, as not to be the immediate object of our senses.

Animalcules are seen only by the assistance of microscopes, and are perhaps more numerous than any other part of the animal creation; but the species, on a close examination, are found to be but few, in proportion to the number of individuals. The most obvious distinction among them is, that some have, and others have not tails; and that some have, and others have not visible limbs. They are usually arranged into three classes. 1. Gymnia, or those which are without limbs. 2. Cercaria, or those which have tails. 3. Arthronia, those which have visible limbs.

ANIME, improperly called gum anime, is a resinous substance imported from New Spain and the Brazils. There are two kinds, distinguished by the names of oriental and occidental. The former is dry, and of an uncertain colour, some specimens being greenish, some reddish. and some of the brown colour of myrrh. The latter is in yellowish-white, transparent, somewhat unctuous tears, and partly in larger masses, brittle, of a light pleasant taste, easily melting in the fire, and

burning with an agreeable smell. Like resins, it is totally soluble in alcohol, and also in oil.

ANIME', in heraldry, a term used when the eyes of any rapacious creature are borne of a different tincture from the creature itself.

ANNALS, in matters of literature, a species *of history, which relates events in the* chronological order in which they happened. They differ from perfect history in this, that annals are a bare relation of what passes every year: whereas history relates not only the transactions themselves, but also the causes, motives, and springs of actions. Hence annals require nothing but brevity, history demands ornament.

ANNEAL. We know too litt' of the arrangement of particles to determine what it is that constitutes or produces brittleness in any substance. In a considerable number of instances of bodies which are capable of undergoing ignition, it is found that sudden cooling renders them hard and brittle. This is a real inconvenience in glass, and also in steel, when this metallic substance is required to be soft and flexible. The inconveniences are avoided by cooling them very gradually, and this process is called annealing. Glass vessels, or other articles, are carried into an oven or apartment near the great furnace, called the leer, where they are permitted to cool, in a greater or less time, according to their thickness and bulk. The annealing of steel, or other metallic bodies, consists simply in heating them, and suffering them to cool again, either upon the hearth of the furnace, or in any other situation where the heat is moderate, or at least the temperature is not very cold.

ANNONA, or *Custard Apple*, a genus of the polyandria poligynia class and order. The characters are: the calyx is a triphylous perianthium: the corolla consists of six heart-shaped petals: the stamina have scarcely any filaments; the antheræ are numerous, sitting on the receptaculum: the pistillum has a roundish germen; no styli: the stigmata obtuse and numerous: the pericarpium is a large roundish unilocular berry, covered with a scaly bark: the seeds are numerous. There are 10 species.

ANNOTTO, in commerce, a kind of red dye, brought from the West Indies. It is procured from the pulp of the seed-capsules of a tree called bixa in South America. See **Bixa.**

The annotto is prepared only by the Spaniards; the mode is as follows: the contents of the fruit or capsule are thrown into a wooden bowl, where as much hot water is poured on them as is necessary to suspend the red matter or pulp. When the seeds are left quite naked, they are taken out, and the wash is left to settle. The water is then poured off, and the sediment dried by degrees in the shade, after which it is made into balls or cakes for exportation.

ANNUAL, an appellation given to whatever returns every year: thus we say, the annual motion of the earth, annual plants, &c.

ANNUAL *plants*, called also simply *annuals*, are such as only live their year, *i.e.* come up the spring, and die again in the autumn.

ANNUITIES, periodical payments of money, amounting to a fixed sum in each year, and continuing for a certain period, as for 10, 50, or 100 years; or for an uncertain period, to be determined by a particular event, as on the failure of a life, or for an indefinite term; which latter are called perpetual annuities. The times of payment are either yearly, *half-yearly, quarterly, weekly, or at any other intervals that may be determined on previous to the commencement of the annuity, or regulated during its continuance.*

All calculations relating to annuities are made on the principle of improving money at compound interest, and are generally for an annuity of 1*l.*, from which the value of any other annuity is easily derived. Let r represent the amount of 1*l.* in one year; that is, 1*l.* increased by a year's interest, then r_n, or r, raised to the power whose exponent is any given number of years, will be the amount of 1*l.* in those years; its increase in the same time is r^n-1; now the interest for a single year, or the annuity answering to the increase, is $r-1$; therefore, as $r-1$ is to r^n-1, so is u (any given annuity) to a its amount. Hence we have

$$\frac{u\times\overline{r^n-1}}{r-1}=a,$$

by which the amount of an annuity for any number of years at any given rate of interest is found. In the same manner the present value of annuities is obtained; for, as 1*l.* is the present value of r_n, its amount in n years, and as the present value of any other amount, and consequently of $\frac{u\times\overline{r_n-1}}{r-1}$ must bear the same proportion to that amount, we have

$$\frac{u\times\overline{1-\frac{1}{r^n}}}{r-1 \qquad r-1}=p.$$

From these theorems, the other cases relating to annuities may be easily deduced; but as the involution of high powers is a tedious operation by common arithmetic, most questions relative to annuities may be more conveniently answered by the help of logarithms.

ANNULET, in architecture, a small square member in the Doric capital, under the quarter round. Annulet is also a narrow flat moulding which is common to divers places of the columns, as in the bases, capitals, &c.

ANOMALISTICAL *year*, in astronomy, the time that the earth takes to pass through her orbit: it is also called the periodical year. The space of time belonging to this year is greater than the tropical year, on account of the precession of the equinoxes.

ANOMALOUS *verbs*, in grammar, such as are not conjugated conformably to the paradigm of their conjugation: they are found in all languages; in Latin the verb *lego* is the paradigm of the third conjugation, and runs thus, *lego, legis, legit;* by the same rule it should be *fero, feris, ferit,* but we say *fero, fers, fert; fero* then is an anomalous verb. In English the irregularity relates often to the preter tense, and passive participle; for example, *give,* were it formed according to rule,

would make *gived* in the preter tense, and passive participle; whereas, in the former, it makes *gave*, and in the latter *given.*

ANONIS, *rest-harrow*, in botany, a genus of plants, the flower of which is papilionaceous, and its fruit a turgid villose pod, containing a few kidney-like seeds.

This genus belongs to the diadelphia decandria class of Linnæus, who calls it *ononis.*

ANSER, the trivial name of the common goose. See **Anas.**

Anser, in astronomy, a star of the fifth or sixth magnitude, in the milky-way, between the swan and eagle.

ANT, in entomology, a well-known insect, much celebrated for its industry and economy. See **Formica** and **Termes.**

ANTARCTIC, in a general sense, denotes something opposite to the artic, or northern pole. Hence,

Antarctic *circle*, in geography and astronomy, is one of the lesser circles of the sphere, and distant only 23° 30′ from the south pole, which is likewise called antarctic, for the same reason.

ANTECEDENT, in grammar, the word to which a relative refers: thus, *God whom we adore*, the word God is the antecedent.

Antecedent, in mathematics, is the first of two terms of a ratio, or that which is compared with the other, as in the ratio of 2 to 3, or *a* to *b*, 2 and *a* are each antecedents.

ANTELOPE, in zoology, a genus of quadrupeds. The generic character is, horns hollow, with a bony core, pointing upwards, annulated or wreathed, permanent; front teeth in the lower jaw, eight; no canine teeth. Antelopes have but lately been included in a separate genus: they were formerly placed under that of the goat. They form a link indeed between the goat and deer kind, but possess sufficiently distinctive marks to entitle them to stand apart from them both. They are in general natives of the hottest part of the globe, and peculiarly of Asia and Africa, Europe having but two species, and America none.

Antelopes have a slender elegant make, and are singularly swift in their motions: they are restless, timid, vigilant, and full of animation. Their chace is a favourite amusement in the East; and such is their speed that the fleetest dogs cannot overtake them: on which account falcons are trained to assail them, and by pecking at their eyes, to check their course, and throw them into confusion.

Antelopes have the singular property of sometimes stopping short, and gazing at their pursuers. The beauty of their eyes affords a favourite object of comparison to eastern poets. They usually prefer hilly countries, and associate in numerous herds. They graze on herbage, or crop the shoots of trees, and their flesh is generally of a very delicate flavour. There are 28 species.

ANTENNÆ, in the history of insects, slender filaments with which nature has furnished the heads of these creatures, being the same with what in English are called horns, or feeders.

ANTHEMIS, in botany, *chamomile*, a genus of the syngenesia superflua class and order. Receptacle chaffy; seeds generally crowned with a slight border; calyx hemispherical, nearly equal; florets of the ray more than five, oblong. There are two divisions of this genus, namely A. with a differently coloured or white ray; and B. ray the colour of the disk or yellow: there are about forty species.

ANTHERA, among botanists, that part of the stamen which is fixed on the top of the filamentum, within the corolla; it contains the pollen or fine dust, which, when mature, it emits for the impregnation of the plant.

ANTHERICUM, spider-wort, a genus of the monogynia order, belonging to the hexandria class of plants; and, in the natural method, ranking under the 10th order coronariæ. The essential character is, corolla of six oblong petals, expanding; the pericarpium is an ovate trisculated capsule, with three cells and three valves. There are between 50 and 60 species.

ANTHISTIRIA, in botany, a genus of the trygynia order, belonging to the triandria class of plants, and, in the natural method, ranking under the 4th order, gramina. There is only one species of this grass, the ciliata or fringed anthistiria, a native of India.

ANTHOCEROS, the *horn flower*, a genus of the order of algæ, and of the cryptogamia class of plants. Of this plant there are three species. 1. A. livis, which is a native of Europe. 2. A. multisidus, a native of Germany, 3. A. punctalus, or spotted anthoceros, a native of Britain.

ANTHOLOGY, ανθολογια, a discourse of flowers, or of beautiful passages from any authors. It is also the name given to a collection of epigrams taken from several Greek poets.

ANTHOLYZA, mad flower a genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the 6th order, ensatæ.

ANTHOSPERMUM, the amber tree, a genus of the diœcia order, belonging to the polygamia class of plants, and in the natural method ranking under the 17th order, stellatæ. The essential characters are; the calyx of the hermaphrodite flower is divided into four parts; there is no corolla; the stamina are four, and the pistilla two; the germen is beneath the flower. Male and female on the same or separate plants. Of this genus Linnæus mentions three species, viz. 1. A. Æthiopica. 2. A. ciliare. 3. A. herbacea.

ANTHOXANTHUM, or **vernal grass**, a genus of the digynia order, belonging to the diandria class of plants; and in the natural method ranking under the 13th order, gramina. The essential characters are: the calyx is a bivalved gluma, with one flower; the corolla is bivalved, obtuse, and without any awn. There are three species, the principal of which, viz. the odoratum is one of the earliest grasses in this country, and imparts the odoriferous smell to new mown hay.

ANTHROPOPHAGIA, signifies the act of eating human flesh.

The origin of this custom, barbarous as it is, some authors trace as high as the deluge. In the southern part of Africa, and in some parts of America, this horrid practice is said still to prevail. Mr. Marsden, in his history of Sumatra, informs us that the battas of that island are anthropophagi. They do not eat human flesh

to satisfy hunger, but as a mode of shewing an abhorrence of their enemies. The objects of this savage repast are prisoners taken in war. When sentence is pronounced, the unhappy victim is tied to a stake; and when mortally wounded by lances thrown at him by the assembled multitude, they rush upon him, cut pieces from his body with their knives, dip them in a dish, previously prepared, of salt and lemon-juice, slightly broil them over a fire, and then devour them with savage enthusiasm.

ANTHYLLIS, *kidney-vetch*, or *lady's finger*, a genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The essential characters are; the calyx is ventricose, and the legumen is roundish and covered. This genus is separated into the A. herbaceous, and the A. shrubby: there are of the former 12 species, and of the latter nine.

ANTICHORUS, in botany, a genus of the octandria monogynia class and order. Calyx four-leaved; petals four; capsule superior, subulate, four-celled, four-valved; seeds numerous. There is only one species, found in Arabia.

ANTIMONY. The word antimony is always used in commerce to denote a metallic ore, consisting of sulphur combined with the metal which is properly called antimony. Sometimes this sulphuret is termed crude antimony, to distinguish it from the pure metal, or regulus, as it was formerly called. According to Prof. Proust, the sulphuret contains 26 per cent. of sulphur.

Antimony is of a dusky-white colour, very brittle, and of a plated or scaly texture. Its specific gravity, according to Brisson, is 6.7021, but Bergman makes it 6.86. Soon after ignition it melts, and by a continuance of the heat it becomes oxidized, and rises in white fumes, which may afterward be volatilized a second time, or fused into a hyacinthine glass, according to the management of the heat: the first were formerly called argentine flowers of regulus of antimony. In closed vessels the antimony rises totally without decomposition. This metallic substance is not subject to rust by exposure to air, though its surface becomes tarnished by that means. Its oxides are a little soluble in water; and in this respect they resemble the oxide of arsenic, by an approach toward the acid state.

Antimony combines readily with the softer metals, and the alloys thus formed, have been hitherto applied chiefly in the manufacture of music plates and printing types. Medicine is indebted to antimony for some of its most active and valuable remedies. The acid of tartar forms with it the preparation called antimoniated tartrate of potass, formerly known by the name of emetic tartar.

ANTIPATHES, in natural history, a genus of worms of the order zoophyta. The animal grows in the form of a plant; the stem within is horny, with small spines; the base is expanded, the outside covered with a gelatinous flesh, and beset with polype bearing warts. There are thirteen species.

ANTIPODES, in geography, a name given to those inhabitants of the globe that live diametrically opposite to one another. They lie under opposite parallels and opposite meridians. They have the same elevation of their different poles. It is midnight with one when it is noon with the other; the longest day with the one is the shortest with the other; and the length of the day with the one is equal to that of the night of the other.

ANTIQUARY, one who studies the remains of former ages. There is a society of antiquaries in London; it was instituted in the year 1751; and another in Edinburgh instituted in 1780.

ANTIQUITIES, a term implying all testimonies, or authentic accounts that have come down to us of ancient times. Antiquities may be considered as the wrecks of history, or such particulars as learned persons have collected from genealogies, inscriptions, monuments, coins, etymologies, archives, instruments, fragments of history, &c. The common division of antiquities is into sacred and profane. The former embraces whatever relates to the history of the Jewish nation; and the latter the subjects connected with political, military, literary and domestic concerns.

The most authentic information on points relating to sacred antiquities is to be obtained from the writings of the Old Testament; the works of Josephus, Shuckford, Prideaux, Godwin, Meusel, Ugolino, and Lowth's Lectures on Hebrew Poetry. On profane antiquity, Potter's Antiquities of Greece, Adams's Roman Antiquities, Horsley's Britannia Romana, and the Itinerary of Antoninus Camden, will be found amply sufficient.

ANTIRRHINUM, SNAPDRAGON, OR CALVES-SNOUT: a genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The essential characters are these; the calyx consists of five leaves: the basis of the corolla is bent backwards, and furnished with pectoria; the capsule is bilocular. There are fifty-two species of the snapdragon; it is an old inhabitant of our gardens, and we have hardly yet a more beautiful flower. The scarlet and crimson kinds are particularly fine.

ANTISCII, in geography, people who live on different sides of the equator, whose shadows at noon are projected opposite ways; the people of the north are antiscii to those of the south.

ANTISTROPHE, among lyric poets, that part of a song and dance in use among the ancients, which was performed before the altar, in returning from west to east, in opposition to strophe.

ANTITHESIS, in rhetoric, a contrast drawn between two things, which serve as shades to set off the opposite qualities of each other.

ANTOECI, in geography, an appellation given to those inhabitants of the earth who live under the same meridian, but on different sides of the equator, and at equal distances from it: the antoeci having the same longitude, and equal degrees of latitude, one north and the other south: their hours of day and night are the same, but they have opposite seasons, of course the longest day to the one is the shortest to the other.

ANTONOMASIA, in rhetoric, a figure by which the proper name of one thing is applied to several others; or, on the contrary, the name

of several things to one. Thus we call a cruel person a Nero; and we say the philosopher to denote Aristotle.

ANVIL, an iron instrument, on which smiths hammer or forge their work, and usually mounted on a firm wooden block. A forged anvil is reckoned better than one of cast work.

AORTA, in antomy, called also arteria magna, a large artery arising with a single trunk from the left ventricle of the heart above its valves, called semilunares, which serves to convey the mass of blood to all parts of the body. See ANATOMY.

APACTIS, in botany, a genus of the dodecandria monogynia class and order. The essential character is, cor. four-petalled; cal. none. There is only one species, a tall tree, a native of Japan.

APARGIA, a genus of the class and order syngenesia polygamia æqualis. The essential character is, cal. subimbricate, with linear, parallel, unequal scales; down plumose, subsessile; recept. naked, subvillose. There are seven species, much resembling the dandelion, with which they were formerly confounded.

APATITE, phosphate of lime. This mineral occurs in tin veins, and is found in Cornwall and Germany. Colours white, green, blue, and red of various shades. The primitive form of its crystals is a regular six-sided prism. Specific gravity between 2.8 and 3.2. When laid on ignited coals it emits a green light, and is almost entirely soluble in nitric acid. By rubbing it shews signs of electricity.

APETALOUS, among botanists, an appellation given to such plants as have no flower-leaves, or corolla.

APEX, in antiquity, the crest of a helmet, out more especially a kind of cap worn by the flamens.

APHÆRESIS, in grammar, a figure by which a letter or syllable is cut off from the beginning of a word.

APHANES, a genus of the monogynia order, and tetrandria class of plants; and in the natural method ranking under the 35th order, senticosæ. The essential characters are: the calyx is divided into eight parts; there is no corolla; the seeds are two, and naked. There is only one species.

APHELIUM, or APHELION, in astronomy, is that point in any planet's orbit, in which it is farthest distant from the sun; being that end of the greater axis of the elliptical orbit of the planet, most remote from the focus wherein the sun is.

APHIS, in entomology, the *puceron*, *vine-fretter*, or *plant-louse*, an extensive genus of the hemiptera order.

Of this very curious insect there are said to be thirty-three species, each of which is attached to a particular plant. They were formerly ranked among the animals which had been classed with the true Androgynes; but Mr. Bonnet has determined their division into males and females. This he did by shutting up a young aphis at the instant of its birth, in perfect solitude which yet brought forth in his sight 95 young ones. Repeated experiments, in this respect, as far as the fifth or sixth generation, all uniformly presenting the observer with fecund virgins, were communicated to the Royal Academy of Sciences; when an unforeseen and very strange suspicion, imparted by Mr. Trembley, to Mr. Bonnet, engaged him anew in a series of experiments. Mr. Bonnet therefore reared to the amount of the tenth generation of solitary aphides, and had the patience to keep an account of the days and hours of the births of each generation. In short, it was discovered, that they are really distinguished by sexes; that there are males and females amongst them, whose amours are the least equivocal of any in the world: that the males are produced only in the tenth generation, and are but few in number: that these, soon arriving at their full growth, copulate with the females: that the virtue of this copulation serves for ten generations; that all these generations, except the first, (from the fecundated eggs) are produced viviparous; and all the individuals are females, except those of the last generation, as already observed.

APHYLLANTHES, LEAFLESS FLOWER OR BLUE MONTPELIER PINK: a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 5th order, tetrapetaloidæ. In character it differs not from the juncus or rush, but in having a calyx of six petals, whereas the juncus has no calyx. There is only one species; viz.

APHYLLANTHES *Montpeliensis*, a native of France.

APIARY, a place where bees are kept, which should be properly defended from high winds, as well as from poultry, hogs, &c. whose dung is extremely offensive to the bees.

APIS, the *Bee*, in natural history, a genus of insects of the order hymenoptera. The mouth is furnished with jaws, and an inflected proboscis, with two bivalve sheaths; wings flat or without plaits; the sting in the female and neutral insects concealed. There are fifty-five species, of which the most remarkable are. 1. *Apis Brasilianorum*, or pale red hairy bee, with the basis of the thighs black: it is large, and a native of America.

2. APIS *cariosa*, is a yellowish hairy bee; it generally builds in rotten trees, and is found in different parts of Europe.

3. APIS *centuncularis*, the leaf cutter, or black bee, has its belly covered with yellow down. The nests of this species are made with leaves curiously plaited like a mat; they dig into the ground and build their nests, some of which are of the size and form of a thimble inserted one within another, and composed of leaves principally the rose leaf.

4. APIS *dentata*, or shining green bee, with black wings, and a kind of teeth on the hind thighs. The tongue of this bee is as long as its body.

5. APIS *ferruginea*, or smooth black bee, with the feelers, mouth, belly, and feet, of an iron colour. This is a small bee, and supposed to be of an intermediate kind between the bee and wasp. It is a native of Europe.

6. APIS *florisomnis*, or black bee, with a cylindrical incurvated belly, having two tooth-like protuberances at the anus, and a kind of prickles on the hind legs. This bee sleeps in flowers; whence the name.

7. Apis *lapidaria*, or red hairy bee, with a yellow anus, builds in holes of rocks.

8. Apis *muscorum*, or yellow hairy bee, with a white belly, builds in mossy grounds. The nests of this species are constructed of moss, in a very curious manner, and protected from the effects of the weather by an arched covering of wax.

9. Apis *rostrata* is distinguished by the upper lip being inflected and of a conical shape, and by the belly being invested with blueish belts. They build their nests in high sandy grounds, and there is but one young in each nest.

10. Apis *terrestris* is black and hairy, with a white belt round the breast, and a white anus; it builds its nest very deep in the earth.

11. Apis *variegata:* the breast and belly are variegated with white and black spots; the legs are of an iron colour. This species is not common in England, but has been found near Bexley, in Kent. It sleeps in the flower of the spotted crane's bill.

12. Apis *violacea* is a red bee, and very hairy, with blueish wings. The violacea is said to perforate trees; and hollow them out in a longitudinal direction; they begin to build their cells at the bottom of these holes, and deposit an egg in each cell, which is composed of the farina of plants, and honey, or a kind of gluten.

13. Apis *mellifica*, the domestic honey bee. This wonderful insect requires to be described under the distinct heads of queen, drone, and working bee. The drones may easily be distinguished from the common or working bees: they are both larger and longer in the body: their heads are round, their eyes are full, and their tongues short. The form of the belly differs from those of both queen and common bees; and their colour is darker than either. They have no sting, and they make a much greater noise when flying, than either the queen or the common bees; a peculiarity of itself sufficient to distinguish them. If a hive is opened in the beginning of spring, not a single drone will be found in it; from the middle of May till the end of June, there will be found commonly from 200 or 300 to 1000; but from August to the following spring it would be in vain to seek for them. They go not out till 11 in the morning, and return before six in the evening. But their expeditions are not those of industry. Their rostrum and feet are not adapted for collecting wax and honey, nor indeed are they obliged to labour. They only hover upon flowers to extract the sweets.

There appears to exist a diversity of opinion among writers on bees respecting the office of the drones. It is asserted by some highly respectable authors that the drone exists in the hive merely for the purpose of impregnating the eggs of the queen after they are deposited in the cells.

This opinion, however, Mr. Bonnet proves to be erroneous, and informs us that the queen stands in no need of the assistance of the drones to fecundate her eggs; and affirms that she lays eggs which produce young bees, without the slightest communication with the drones. This position he supports by the testimony of several other writers, particularly that of Schirach.

According to Mr. Bonnet, the queen is easily distinguished by her form, size, and colour. She is longer, and her wings are shorter in proportion to her body, than those of the other bees. The wings of the common bees and of the drones cover their whole bodies, while those of the queen scarcely reach beyond the middle. Her hinder part is more tapering, her belly and legs are yellower, and her upper parts are darker than those of other bees. The queen bee is furnished with a sting, but is extremely sparing in the use of it: so much so that one may handle her, and even teaze her without provoking her resentment.

The common bees, says Mr. Bonnet, are endowed with the powerful faculty of raising a queen bee from an egg in a common cell. For this purpose they choose a common cell with an egg in it, and inject into it a white liquid matter from their proboscis; they then build on the edges of the cell and enlarge it. On the fifth day the royal maggot appears in the form of a semicircle, and floats about on the top of the liquid matter, or swims in the midst of it; and on the seventh day the cell is sealed up. During this period the maggot undergoes various metamorphoses, but still having no resemblance to a bee, till the 14th or 15th day, when instead of the gross maggot there appears a charming young queen bee.

When a queen dies, the bees of her hive immediately cease working, consume their own honey, fly about their own and other hives at unusual hours, when other bees are at rest, and pine away if not soon supplied with another sovereign. Her loss is proclaimed by a clear and uninterrupted humming. This sign should be a warning to the owner of the bees to take what honey remains in the hive, or to procure them another queen. In this last case the flock instantly revives, and pleasure and activity are apparent through the whole hive. The dissection of the queen bee shows evidently that she lays many thousand eggs. It is computed that the ovaria of a queen bee contain more than 5000 eggs at one time; and therefore it is not difficult to conceive that a queen bee may produce 10,000 or 12,000 bees, or even more, in the space of two months.

The working or common bee, is smaller than either the queen or the drone bee. They have four wings fastened to their middle part, by which they are not only enabled to fly with heavy loads, but also to make those well-known sounds and hummings to each other, which are supposed to be their only form of speech.

The honey-bladder of the bee when full, is about the size of a small pea, and is so transparent that the colour of the honey may be distinguished through it. The sting, which is hollow and horny, is connected to the belly by certain small muscles, by which the bee can dart it out, and draw it in with great force and quickness. It is about the 6th part of an inch in length, largest at the root, and tapering towards the point. The wound proves mortal to numerous insects; and the loss of the sting is accompanied by death to the bee herself, as it generally draws after it part of her entrails.

There are some curious instances on record of the command which some persons have obtained over bees. Mr. Wildman informs us that he caused swarms to light where he pleased

almost instantaneously: he ordered them to settle on his head, then removed them to his hand, and commanded them to depart and

has taught me, that as soon as I turn up a hive, and give it some taps on the sides and bottom, the queen immediately appears to know the cause of this alarm; but soon retires again among her people. Being accustomed to see her so often, I readily perceive her at first glance; and long practice has enabled me to seize her instantly, with a tenderness that does not in the least endanger her person. When possessed of her, I can without injury to her, or exciting that degree of resentment that may tempt her to sting me, slip her into my other hand, and, returning the hive to its place, hold her there, till the bees missing her, are all on wing, and in the utmost confusion. When the bees are thus distressed, I place the queen wherever I would have the bees to settle. The moment a few of them discover her, they give notice to those near them, and those to the rest; the knowledge of which soon becomes so general, that in a few minutes they all collect themselves round her; and are so happy in having recovered this sole support of their state, that they will long remain quiet in their situation. Nay, the scent of her body is so attractive of them, that the slightest touch of her, along any place or substance, will attach the bees to it, and induce them to pursue any path she takes."

When the bees begin to work in their hives, they divide themselves into four companies, one of which roves in the fields in search of materials; another employs itself in laying out the bottom and partitions of their cells; a third is employed in making the inside smooth from the corners and angles; and the fourth company brings food for the rest, or relieves those who return with their respective burdens. But they are not kept constant to one employment; they often change the tasks assigned them; those that have been at work being permitted to go abroad, and those that have been in the fields already take their places. They seem even to have signs by which they understand each other; for when any one of them wants food, it bends down its trunk to the bee from whom it is expected, which then opens its honey-bag, and lets some drops fall into the other's mouth, which is at that time opened to receive it. Their diligence and labour are so great, that, in a day's time, they are able to make cells, which lie upon each other, numerous enough to contain 3000 bees.

The habitations of bees ought to be very close; and what their hives want from the negligence or unskilfulness of man, these animals supply by their own industry. For this purpose they make use of a resinous gum, which is more tenacious than wax, and differs greatly from it. This the ancients called *propolis*. It will grow considerably hard in the hive, though it will in some measure soften by heat, and is often found different in consistence, colour, and smell. It has generally an agreeable aromatic odour when it is warmed; and by some it is considered as a most grateful perfume. When the bees begin to work with it, it is soft; but it acquires a firmer consistence every day, till at length it assumes a brown colour, and becomes much harder than wax.

Bees anxiously provide against the entrance of insects into the hive, by gluing up with wax or propolis the smallest holes in it. Some stand as sentinels at the mouth of the hive, to prevent insects of any kind from getting in. But if a snail or other large insect should get in, notwithstanding all resistance, they sting it to death, and then cover it over with a coat of propolis, to prevent the bad smell or maggots which might proceed from the putrefaction of such a large animal.

Bees are particularly sensible of the approach of stormy weather; and on such occasions they are sometimes seen hurrying to the hive in such numbers that the doors of their habitations are too small to admit them. When a hive has become too crowded, a part of the bees single out a young queen, go in quest of a new habitation, and having found one, they instantly set to work to procure materials for building and food with great diligence; and they are said to produce more wax during the first fortnight, than they do all the rest of the year.

The balls which we observe attached to the legs of bees returning to the hives, are not wax, but a powder which the bee collects by rolling itself in the cup of the flower on which it rests, and which it afterwards brushes off with its hind legs, kneads into balls, eats, and by digestion forms into wax. When this substance is not all wanted, it is laid up in repositories to be kept in store, and is known by the name of bee-bread.

The materials of which bee-hives are made should be such as to secure as far as possible the health and comfort of the bees. Long experience has established the general superiority of the common straw hives, although it must be confessed that single boxes have several advantages which straw hives have not. When the bees require more room it is easily afforded by adding a few rolls to the lower part of the hive. Particular attention is requisite in the choice of stock-hives. In September every stock-hive should contain as much honey as will furnish a supply of food for the bees till June. They ought also to be full of combs, and should weigh about 30lb. each.

Bees generally first swarm in May; and seldom before ten o'clock in the morning, or after three in the afternoon. Just before swarming, an unusual silence may be observed in the hive; after this, as soon as one takes flight, they all follow. As soon as the swarm settles, the bees must be got into the new hive as speedily as possible, to prevent their taking flight again. During the winter season the bees are in a lethargic state, hence little food supports them; but as they frequently revive in a warm sunny day, the hive should be provided with a plate of fine honey, covered with a piece of paper having holes in it, through which the bees may feed without daubing themselves.

In abstracting the honey from the hive, it is common in this country to suffocate the bees with the fumes of burning sulphur; but although this practice is strenuously supported by many, it is obviously cruel, and, in every respect, unnecessary, and at variance with the laws of economy.

The situation of an apiary is a matter of very

great importance. It should face the south, and have the advantage of as uniform a temperature as possible; it is convenient to have it near the house, but it should not be within the sphere of offensive smells, or liable to the rapacity of vermin. Hornets are particularly hostile to bees, and will do the hive great injury if suffered to intrude. On this account it is recommended by writers on bees, to destroy their nests, and thus, as far as can be done, to rid the vicinity of such formidable enemies.

APIUM, PARSLEY, in botany, a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is oval, and streaked; the involucrum consists of one leaf, and the petals are inflected. There are only two species, the culture of which is well known, viz. 1. Apium graveolens, or smallage, or celery, a native of England; and, 2. Apium petroselinum, or common parsley, a native of Sardinia.

Smallage, when improved by culture, is termed celery, and there is scarcely a more desirable root, especially as it is a winter sallad. It is aperient and tonic.

With respect to the 2d sort, the roots and seeds of the petroselinum are used in medicine. The root of parsley is one of the five aperient roots; if liberally used, it is apt to occasion flatulencies; and thus, by distending the viscera, produces a contrary effect to that intended by it; the taste of this root is somewhat sweetish, with a light degree of warmth and aromatic flavour.

APLANATIC, a term applied to that kind of refraction which entirely corrects the aberration of the rays of light, and the colour depending on it, in contradistinction to the word achromatic, in which there is only a partial correction of colour.

APLUDA, a genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is a bivalved gluma: the floscules of the female are sessile, and the male floscules are furnished with pedunculi; the female has no calyx; the corolla has a double valve; there is but one stylus, and one covered seed. The male has three stamina. There are 4 species.

APOCYNUM, in botany, a genus of the pentandria digynia class and order. Corolla campanulate; nectareous filaments five, alternating with the stamina. There are 14 species.

APOGEE, in astronomy, that point in the orbit of a planet, or the sun which is farthest from the earth. This term properly belongs to the ancient astronomy, which was much taken up in ascertaining the apogee and perigee: modern astronomers have laid aside these terms, and instead of them use the terms aphelium and perihelium.

APOLOGUE, in literature, an ingenious method of conveying instruction under a feigned relation, called a moral fable. The fables of Æsop are a model of this kind of writing.

APOPLEXY, a distemper in which the patient is suddenly deprived of the exercise of all the senses, and of voluntary motion; while a strong pulse remains with a deep respiration, attended with a stertor, and the appearance of a profound sleep.

APOSTROPHE, in rhetoric, a figure by which the orator addresses a person either absent or dead as if he was present; or appeals to angels and to men, to rocks, groves, &c. Thus Adam in Milton's Paradise Lost

> O woods, O fountains, hillocks, dales, and bowers,
> With other echo, &c.

APOTHECARY, one who practises the art of pharmacy. In London, the apothecaries are one of the city companies, and by an act which was made perpetual in the ninth year of George I. are exempted from serving upon juries, or in ward and parish offices. They are obliged to make up their medicines according to the formulas prescribed in the college dispensatory, and are liable to have their shops visited by the censors of the college, who are empowered to destroy such medicines as they think not good.

APPARATUS, a term used to denote a complete set of instruments, or other utensils, belonging to any artist or machine: thus we say, a surgeon's apparatus, a chemist's apparatus, the apparatus of the air-pump, microscope, &c.

APPARENT, among mathematicians and astronomers, denotes things as they appear to us, in contradistinction from real or true: thus we say, the apparent diameter, distance, magnitude, place, figure, &c. of bodies.

APPEAL, in law, the removal of a cause from an inferior to a superior court or judge, when a person thinks himself aggrieved by the sentence of the inferior judge. Appeals lie from all the ordinary courts of justice to the house of lords.

APPEARANCE, in law, signifies a defendant's filing common or special bail, on any process issued out of a court of judicature.

In perspective, appearance is the projection of a figure or body on the perspective plane.

In astronomy it signifies the same as phænomena, or phases; and in physiology, the same as phasmata.

APPELLATIVE, in grammar, a noun, or name, which is applicable to a whole species or kind, as man, horse; in contradistinction to a proper name.

APPELLOR, or APPELLANT, in law, he who has committed some felony, or other crime, which he confesses, and appeals, that is, accuses his accomplices.

APPENDANT, in law, any thing that is inheritable, belonging to some more worthy inheritance; as an advowson, common, or court, may be appendant to a manor, land to an office, &c. but land cannot be appendant to land, for both are corporeal inheritances, and one thing corporeal cannot be appendant to another.

APPLICATION, signifies the act of applying one thing to another by bringing them nearer together: thus a longer line or space is measured by the application of a less; and motion is determined by the successive application of any thing to different parts of space. The term is used in the operations of arithmetic, geometry, &c.

APPLICATION of one science to another, signifies the use that is made of the principles of the one for augmenting and perfecting the other. Thus algebra has been applied to geometry, and vice versa, and both are made use

of in illustrating and demonstrating the principles of mechanics, astronomy, navigation, &c. See GEOMETRY.

APPOINTEE, in heraldry, the same as aguisée; thus we say, a cross appointée, to signify that which has two angles at the end cut off, so as to terminate in points.

APPORTIONMENT, in law, the division of a rent into parts, in the same manner as the land out of which it issues is divided: for example, if a person leases three acres of land for a certain rent, and afterwards grants away one acre thereof to another: the rent shall be apportioned between them.

APPOSITION, in grammar, the placing two or more substantives together, in the same case, without any copulative conjunction between them; as, *ardebat Alexin delicias domini.*

APPRAISING, the valuing or setting a price on goods. This is usually done by a sworn appraiser, who, if he values the goods too high, is obliged to take them at the price appraised.

APPREHENSION, in logic, the first or most simple act of the mind, whereby it perceives, or is conscious of some idea: it is more usually called perception.

APPRENTICE, a young person bound by indenture to some tradesman, in order to be instructed in the mystery or trade. By the laws of England, a master may be indicted, for not providing for, or for turning away his apprentice; and upon complaint from a master that he neglects his duty, an apprentice may be committed to Bridewell, or be bound over to the sessions. By 5 Eliz. no person can exercise any trade in any part of England, without having served a regular apprenticeship of at least seven years. No trades, however, are held to be within the statute but such as were in being at the making of it in the reign of Elizabeth.

APPROACHES, in fortification, the works thrown up by the besiegers, in order to get nearer a fortress, without being exposed to the enemy's cannon: such, in a more particular manner, are the trenches, which should be connected by parallels, or lines of communication.

APPROPRIATION, the annexing a benefice to the proper and perpetual use of a religious house, bishopric, college, &c. Where the king is patron, he may make appropriations himself; but in other cases, after obtaining his licence in chancery, the consent of the ordinary, patron, and incumbent is requisite. Appropriations cannot be assigned over, but those to whom they are granted may make leases of the profits There are in England 2845 impropriations.

APPROVER, in law a person, who being indicted of treason or felony, for which he is not in prison, confesses the indictment; and being sworn to reveal all the treasons and felonies he knows, enters before the coroner his appeal against all his partners in the crime.

APPROXIMATION, in arithmetic and algebra, the coming nearer and nearer to a root or other quantity sought, without expecting to be ever able to find it exactly. There are several methods for doing this, to be found in mathematical books, being nothing but infinitely converging series, some approaching quicker, others slower towards the truth.

By such an approximation the value of a quantity may be found, though not to the utmost degree of exactness, yet sufficiently so for practice. Thus $\sqrt{2}=1.41421356$, &c. $=$ the approximating series $1+\frac{4}{10}+\frac{1}{100}+\frac{4}{1000}+\frac{2}{10000}+$, &c. or supposing $x=10$, equal to the series $1+\frac{4}{x}+\frac{1}{x^2}+\frac{4}{x^3}+\frac{1}{x^4}+,=1+4x^{-1}+x^{-2}+4x^{-3}+2.\ ^{-4}+$, &c.

APPULSE, in astronomy, the approach of a planet towards a conjunction with the sun, or any of the fixed stars.

APPURTENANCES, in common law, signify things corporeal and incorporeal, that appertain to another thing as principal; as hamlets to a manor, and common of pasture and fishery.

APSIS, in astronomy, a term used indifferently for either of the two points of a planet's orbit, where it is at the greatest or least distance from the sun or earth. Hence the line connecting these points is called the line of the apsides.

APTENODYTES, in ornithology, a genus of birds that seems to hold the same place in the southern parts of the world a[illegible] do in the northern. According to [illegible] this is the genus penguin. It is seen only in the temperate and frigid zones on that side of the equator which it frequents.

APTERA, in the Linnæan system of zoology, the seventh and last order of insects, the distinguishing characteristic of which is, that the insects comprehended in it have no wings: such are the louse, the flea, the podura, the monoculus, the acarus, the spider, the scorpion, and the crab.

AQUAFORTIS. This name is given to a weak and impure nitric acid, commonly used in the arts. It is distinguished by the terms *double* and *single*; the single being only half the strength of the other. The artists who use these acids call the more concentrated acid, which is much stronger even than the double aquafortis, *spirit of nitre*. This distinction appears to be of some utility, and is therefore not improperly retained by chemical writers.

AQUA *Regia*. This acid is now termed by chemists nitro-muriatic acid, being composed of a mixture of the nitric and muriatic acids.

AQUEDUCT, a construction of stone or timber, on an uneven tract of country, to preserve the level of water, and to convey it from one place to another. Some of the aqueducts built by the Romans were very magnificent; that constructed by Louis XIV. for carrying the Bucq to Versailles is 7000 fathoms long, with 2560 fathoms of elevation, and contains 242 arcades.

AQUARIUS, in astronomy, a constellation which makes the eleventh sign in the zodiac, marked thus, ♒. It consists of 45 stars in Ptolemy's Catalogue, of 41 in Tycho's, and in the Britannic Catalogue, of 108.

AQUEOUS *humour*, or the watery humour of the eye, it is the first and outermost, and that which is less dense than either the vitreous or crystalline. It is transparent and colourless like water, and fills up the space that lies between the cornea and the crystalline humour.

AQUILLARIA, a genus of the class and order decandria monogynia. The essential character is, calyx five cleft; corolla, none;

nectary, pitcher-shaped, half five cleft with bifid clefts: capsula superior, woody, too celled, two valved: seeds solitary.

produced by a disease in this tree, which finally kills it.

AQUILEGIA, COLUMBINE, in botany, a genus, of the pentagynia order, belonging to the polyandria class of plants; and, in the natural method, ranking under the sixteenth order, multisiliquæ. It has no calyx; the petals are five, with a horn-like nectarium inserted between each; and there are five separate capsules. There are five species.

ARABIC (GUM). This is reckoned the purest of gums, and does not greatly differ from gum Senegal, vulgarly called gum seneca, which is supposed to be the strongest, and is on this account, as well as its greater plenty and cheapness, mostly used by calico printers and other manufacturers. The best is of a white colour. It is good in fluxes and catarrhs; and is used for painting in water colours. [illegible] gums of the plum and the cherry-tree [illegible]rly the same qualities as gum arabic. All these substances faciliate the mixture of oils with water.

ARABIS, *bastard tower-mustard*; a genus of the siliquose order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. The generic mark consists in [illegible] nectiferous glands which lie on the inside of each leaf of the calyx. There are 21 species, but none of them remarkable.

ARACHIS, in botany, the ground nut, a genus of the diadelphia decandria class; the flower is papilionaceous, having three petals; the fruit is an oblong pod, contracted in the middle. There are two species which grow in Peru, Brazil, and Carolina; it furnishes a considerable article of food for the negroes.

ARACHNOIDES, in zoology, a name given to those *echini marini*, or sea hedgehogs, which are of a circular form, but variously indented at the edges.

ARALIA, in botany a genus of plants with rosaceous flowers, and succulent berries, containing each a single oblong, and hard seed. It belongs to the *pentandria pentagynia* class of Linnæus. There are nine species, most of them shrubs, and natives of China and America; some are hardy enough to stand our climate in sheltered situations.

ARANEA, in natural history, the *spider*, a genus of insects of the order aptera. The mouth is furnished with short horny jaws; lip rounded at the apex; feelers two, incurved, jointed, very acute at the tip, clubbed with the genitalia in the male; no antennæ; the eyes are eight, or rarely six; feet eight, the anus furnished with papillæ, or teats for spinning. They fix the ends of their threads by applying these nipples to any substance, and the thread lengthens in proportion as the animal recedes from it. They can stop the issuing of the threads by contracting the nipples, and reascend by means of the claws on their feet, much in the same manner as sailors warp up a rope. Naturalists enumerate upwards of fifty species of aranea, the most remarkable of which are the following

1. Aranea Aquatica, or water-spider, frequents the fresh waters of Europe: it is amphibious. In the water its belly appears cover-

its body, and prevent the immediate contact of the water. This bubble of air is made the substance of its dwelling, which it constructs under water: for it fixes several threads of fine matter, to the stalks of plants in the water; and then ascending to the surface, thrusts the hinder part of its body above water, drawing it back again with such rapidity, that it attaches underneath a bubble of air, which it has the art of detaining under water, by placing it underneath the threads, and which it binds like a covering around the air bubble. Then it ascends for another air bubble; and thus proceeds until it has constructed a large aerial apartment under water. It lodges during the winter in empty shells, which it shuts up with a web.

2. Aranea Avicularia is a native of America, and feeds upon small birds, insects, &c. The bite of this spider is accounted as venomous as that of the serpent.

3. Aranea Calycina lives in the cups of flowers, and catches bees and flies.

4. Aranea Cucurbitina has a globular yellow belly, with a few black spots. It lives in the leaves of trees, and encloses its eggs in a soft net.

5. Aranea Diadema is the largest spider this country produces. The abdomen is of an oval form, downy, and of a ruddy yellow colour. The upper part is adorned with black and white circles and dots, having a longitudinal band in the middle, composed of oblong pearl-coloured spots. The legs are of a pale green colour, annulated with dark purple or black. It inhabits the birch tree.

6. Aranea Fasciata, with yellow bands round the belly, and dusky rings on the legs, is a native of Barbary; and is as large as the thumb.

7. Aranea Fimbriata has a black oblong belly, with a white line on each side, and dusky coloured legs. It lives in water, upon the surface of which it runs with great swiftness.

8. Aranea Holosericea has an oval belly covered with a down, like velvet; at the base, or under part, it has two yellow spots. It is found in the folded leaves of plants.

9. Aranea Labyrinthica, with a dusky oval belly, and a forked anus. The web of this species is horizontal, with a cylindrical well or tube in the middle.

10. Aranea Ocellata has three pair of eyes [illegible] its thighs. It is about the size of the tarantula, of a pale colour, with a black ring round the belly, and two black spots on the breast. It is a native of China.

11. Aranea Saccata lives in the ground, and carries a sack with its eggs, wherever it goes. This sack it glues to its belly, and will rather die than leave it behind.

12. Aranea Tarantula has the breast and belly of an ash colour; the legs are likewise ash coloured, with blackish rings on the under part: two of its eyes are larger than the other, red, and placed in the front; four other eyes are placed in a transverse direction towards

the mouth. It is a native of Italy, Cyprus, Barbary, and the East Indies. The tarantula is the largest of all the European spiders; but the extraordinary symptoms of sickness difficulty of breathing, faintness, &c. which are supposed to ensue from the bite of this insect, as well as their supposed cure by the power of music alone are now exploded, as fabulous.

There is one particular in the history of spiders that deserves attention, viz. their power of flight. In the autumnal season they ascend the air, and fill it with that infinity of floating silky threads which are so conspicuous at that season of the year. When inclined to make these excursions, the spider ascends some eminence, as the top of a wall, or the branch of a tree; and turning itself with its head towards the wind, ejaculates several threads, and rising from its station, commits itself to the gale, and is thus carried far beyond the height of the loftiest towers. When satisfied with their journey and their prey, they suffer themselves to fall by contracting their limbs, and gradually disengaging themselves from the thread that supports them.

ARBITER, in civil law, is a judge appointed by the magistrate, or chosen by the parties at variance, to decide their differences according to law. There is a difference between an arbiter and an arbitrator; the former must judge according to the usages of the law, but the latter is allowed a discretionary power.

ARBITRATION, a power given by two or more contending parties to some person, or persons to determine the dispute between them: if the two do not agree, it is usual to add that another person be called as umpire, to whose sole judgment it is then referred. The submission to arbitration is the authority given by the parties in controversy to the arbitrators, to determine and end their grievances; and this being a contract or agreement, must not be strictly taken, but largely, according to the intent of the parties submitted.

ARBITRATOR, a private extraordinary judge, chosen by the mutual consent of parties, to determine controversies between them. Arbitrators are to award what is equal between both parties, and the performance must be lawful and possible. An action of debt may be brought for money adjudged to be paid by arbitrators.

ARBUTUS, the strawberry-tree, in botany, a genus of the decandria monogynia class of plants. The essential character is, calyx five parted; corolla ovate, diaphanous at the base: capsule five celled. The fruit is a roundish berry, containing five cells, and is edible. There are ten species.

ARC, in geometry, part of the circumference of a circle lying between two points, by which the quantity of the whole circle, or line, or something else sought may be found.

ARCH *of equilibration* is that which is in equilibrium in all its parts, having no tendency to break in one part more than in another, and which is therefore safer and stronger than any other figure. Every particular figure of the extrados, or upper side of the wall above an arch, requires a peculiar curve for the under side of the arch itself, to form an arch of equilibration, so that the incumbent pressure on every part may be proportional to the strength or resistance there. When the arch is equally thick throughout, a case that can hardly ever happen, then the catenarian curve is the arch of equilibration; but in no other case; and therefore it is a great mistake in some authors to suppose that this curve is the best figure for arches in all cases; when in reality it is commonly the worst. This subject is fully treated in Dr. Hutton's Principles of Bridges, prob. 5.

ARCS, *equal*, those which contain the same number of degrees, and whose radii are equal.

ARC, *diurnal*, that part of a circle described by a heavenly body, between its rising and setting; as the nocturnal arch is that described between its setting and rising; both these t[illegible]r are always equal.

[illegible]c *of progression* or *direction*, an arch [illegible]he zodiac, which a planet seems to pass [illegible]r, when its motion is according to the [illegible]ns.

ARCHERY, the art of shooting with a bow and arrow; an art of which the English have always been reckoned fond, and in which they have excelled. Many of the ancient kings greatly encouraged the practice of archery. Hence Edward III. ordered a complaint to be lodged against the sheriff of London, for permitting other useless games to be pursued, when the leisure time of his people upon holidays ought to be spent in the recreations of archery. In the reign of Edward IV. an act was made that every Englishman should have a bow of his own height to be made of yew, hazel, ash, &c.: and mounds of earth were ordered to be made in every township, and the inhabitants to practise archery, under certain penalties.

The Artillery Company of London are the remains of the ancient fraternity of bow men, or archers. There are several companies of archers in England, as the Woodmen of Arden; and in Scotland there is the Royal Company of Archers, which consists of upwards of 1000 members, among whom are most of the Scottish nobility.

ARCHIL, a moss of a grey colour, which grows on the rocks in many parts of the Archipelago, and on the western coast of England. It yields a purple tincture, fugitive indeed, but very beautiful, which is the best chemical test for acids and alkalis, and is known by the name of tincture of litmus. By the addition of tin it is rendered durable as a dye, and it then approaches to scarlet. Archil however is most commonly used to give a bloom to pinks and other colours. It readily gives out its colouring matter to water or any spirit.

ARCHITECT, a person skilled in architecture, or the art of building; who forms plans and designs for edifices, conducts the work, and directs the artificers employed in it. A thorough knowledge of mathematics, is an indispensable qualification in an architect; he should also be expert in perspective drawing.

ARCHITECTURE, is the art of building, or the science which teaches the method of erecting buildings, either for habitation, defence, or ornament. It is an art of the first necessity, and almost coeval with the human species. Man, from seeking shade and shelter under the trees of the forest, soon felt the necessity and saw the utility of bending them to more commodious forms than those in which

he found them disposed by nature. To huts made of trees and branches leaning together at top, and forming a conical figure plastered with mud, succeeded more convenient, square, roofed habitations; the sides of these habitations, and the inner supports of the cross beams of the roofs, being trunks of trees; from them were derived those beautiful, symmetrical columns, *the Orders of Architecture.*

Although this art was cultivated by the ancient Egyptians, Assyrians, and Persians, yet the Greeks justly claim the honour of having raised the first structures in which elegance and symmetry were combined with comfort and convenience in the plan.

The established five orders of architecture, the Tuscan, the Doric, the Ionic, the Corinthian, and the Composite, were brought to perfection under the Greeks and Romans. Modern efforts have added little or nothing to the beauty and symmetry of these columns, and the parts dependent on them; but much has been done in the internal improvement of mansions and houses.

OF THE FIVE ORDERS.

The Tuscan Order.

Although there are no ancient remains of it, this order is generally placed first on account of its plainness; and Vitruvius only mentions in an indistinct manner the general proportions of it. The Trajan and Antonine columns at Rome are commonly called Tuscan, though they have eight diameters for their height, and the torus and capitals do not exhibit Tuscan plainness. It is probable the Tuscan is only a simplification of the Doric, of which there are so many ancient remains; but to Tuscany it evidently owes its name.

Its proportions are, fourteen modules or seven diameters for the height of the column; three modules and a half for the whole entablature, which divided into ten equal parts, three are for the height of the architrave, three for the frize, and four for the cornice: the capital is in height one module. The base, including the lower cincture of the shaft, is one module; and the shaft, is twelve modules. For interior use the height of the column may be fourteen modules and a half, or fifteen modules, and the increase may be in the column only.

The Doric Order.

The origin of this order is ascribed to Dorus, who built a temple to Juno, in the ancient city of Argos. But afterwards, Ion, who built a temple to Apollo in Asia, fixed the proportions of it; and being guided by the example of nature in the structure of man, gave six times the length of the foot, or diameter of its base, for the height.

The practice of the moderns allows eight diameters, with a base; an addition no less useful than elegant. Some of the most ancient columns of this order are fluted, and some squared off.

The place and form of the triglyph, an ornament peculiar to this order, are both evidently derived from the ends of projecting joints, laid from the inner to the outer walls of buildings. When as much of the timber as appeared unhandsome was cut off, tablets like the triglyphs now in use, were fastened on the ed ends, and produced a pleasing effect. The triglyphs, interjoists, and metope, in Doric work, had their origin from the disposition of the timbers in the roof: afterwards, in other works, some made the rafters that were perpendicular over the triglyphs to project outward, and carved their projecture; hence as the triglyphs arose from the disposition of the joists, so the mutules under the corona were derived from the projecture of the rafters; wherefore, in stone or marble structures, the mutules are represented declining, in imitation of the rafters; and also on account of the droppings from the eaves, it is proper they should have such declination. The skull of the ox is peculiar to the Doric order.

According to the modern proportions of this order, the height of the column, including its capital and base, is sixteen modules, the height of the entablature four modules, which being divided into eight parts, two are for the architrave, three for the frize, and three for the cornice · the base will be one module in height, the capital thirty-two minutes, or little more.

The Ionic Order.

Vitruvius ascribes this order to Ion mentioned above, but it is more probable that it had its origin from the people of Ionia. The Ionic column is more slender than the Doric, but more graceful. Its ornaments are elegant, and in a style between the richness of the Corinthian, and the plainness of the Tuscan. The general appearance of it is simple, yet graceful and majestic, whence figuratively it has been compared to a female, rather decently than richly clad, whose locks of hair decorated with flowers, are represented by the volutes of the capital, ornamented with festoons. When Hermogenes built the celebrated temple of Bacchus, at Teos, he rejected the Doric, after the marbles had been prepared, and adopted the Ionic in its stead. And, indeed, the difficulties of adjusting the mutules, metope, and triglyphs in Doric buildings, together with the heavy appearance of that order, naturally would cause the Ionic to be preferred. Denteles, which are peculiar to this order, represent the assers, or small rafters that support the tiles: on the ancient Ionic columns, and volutes are usually placed parallel. and to Michael Angelo is ascribed the executing them on an angular plan, though it is certain that some remains of antiquity furnish similar examples. The modern proportions are: eighteen modules for the height of the column, and four modules, or four and a half, for the entablature. The capital is twenty-one minutes, and the base thirty minutes in height; the shaft may be plain, or fluted with twenty, or twenty-four flutings, whose plan should be a little more than a semi-circle, and the breadth of the fillet between them, one third of the flute. The ornaments of the capital are to correspond with the flutings of the shaft, and there must be an ove above the middle of each fluting. The entablature being divided into ten equal parts, three are for the architrave, three for the frize, and four for the cornice. In interior work, where delicacy is required, the height of the entablature may be reduced to one fifth of the height of the column.

The Corinthian Order.

The Corinthian order, which is the finest of

all the orders, has evidently arisen from the two former, having nothing peculiar to itself except the capital, the origin of which is given under the word Abacus. Scamozzi calls it the virginal order, from the delicacy, tenderness, and beauty of the whole composition. The most correct specimens of this order that remain in existence are to be collected from the Stoa, the arch of Adrian, the monument of Lysicratus at Athens, the Pantheon of Agrippa and the three columns of the Campo Vaccino at Rome, particularly the last.

The modern proportions of this order are the following: twenty modules for the height of the column; the entablature, five modules; the base one module, and may be either Attic or Corinthian. The capital is seventy minutes in height; the proportion in the entablature, is the same as in the Tuscan and Ionic orders. If the entablature is enriched, the shaft of the column may be fluted, and the flutings may be fitted to one third part of their height with cabling; and in rich decorations, the cabling may be composed of reeds, husks, ribbons, flowers, &c.

The capital is enriched with olive-leaves, as are almost all the antiques of this order at Rome; the acanthus being seldom employed, but in the Composite. The entablature may be reduced to two-ninths or one-fifth of the height of the column: in which case it is best to use the Ionic entablature, or reduce the denteles of the cornice.

The Composite Order.

In a successful attempt at pleasing variety and novelty, the Romans produced the composite order, by combining the proportions and enrichments of Corinthian, with the angular volute of the Ionic.

The omission of the upper row of leaves in the capital, and the addition of the Ionic volute, give it a bolder aspect than the Corinthian; uniting elegance and a very pleasing projection. In the triumphal arches of Rome, erected at the height of its splendour, it was used with a happy effect, as well as in many other examples in that city.

The height of the column is twenty modules, according to modern proportions; that of the entablature five modules; the capital is seventy minutes in height. The base measures the same as in the Doric and Ionic orders; and as the module is less, all its parts will be more delicate. The shaft may be enriched with twenty or twenty-four flutings, and the principal members of the entablature may have the same proportions as in the two former orders.

Different Parts of an entire Order.

Every order consists of three divisions; the pedestal, the column, and the entablature. The *pedestal* consists of a base or plinth, the dado, and the cornice. The pedestal is used to elevate the column to a necessary height. The *column* includes a base, a shaft, and a capital. The *entablature* consists of an architrave, a frize, and a cornice. The *plinth* is so called from a brick or flat square stone, on which columns, in the early state of architecture, were originally placed. The *dado*, or *die*, is so called from being of the form of a cube. The *cornice* is from corona a top, or summit. The *base* of the column is its foundation. The *shaft* is that straight part of a column, comprehended between the base and capital, resembling a pillar The *capital* is so denominated from caput, the head; the *abacus* is the upper member of the column, and serves as a covering. The *architrave* is so called from two Greek words, signifying, "principal beam," on account of the architrave being the principal support to the entablature. The *frize* is a large flat face, which was sometimes enriched with the figures of animals, and is so called from a Greek word signifying a fringe or border.

Some of the smaller members are, (1.) The *torus*, which is the swell above the plinth. (2.) The *astragal*, a small round member in the form of a ring, which terminates the extremities of the column. (3.) The *scotia* is a hollow moulding used in bases, and receives its name from the strong shadow produced by the concavity. Each column has its particular *base*; the Tuscan base is the most simple, having only a torus and a plinth: the Doric has an astragal more than the Tuscan. To the Ionic base the torus is larger on a double scotia, with two astragals intervening. The Corinthian base has two toruses, two scotias, and two astragals. In the Composite base, there is one astragal less than in the Corinthian. *Corona* is a large flat member in a cornice used to screen the under parts, and to prevent the rain from running down the column. The name of *soffit* is given to the under part of the corona.

The diminution of Columns.

Columns are generally diminished one-sixth part of their lower diameter, which diminution begins at one third part of their height. Some architects allow a small swell in the lower part of the middle division of the pillar.

But in columns from fifteen to twenty feet high, the lower diameter being divided into six parts and a half, take five parts and a half for the diameter at the top. Columns from twenty to thirty feet high are diminished one-seventh. From thirty to forty feet, the lower diameter being divided into seven parts and a half, six and a half may be taken for the upper diameter; and from forty to fifty feet high, they may be diminished one-eighth part, and so on in proportion.

Pedestals, Pilasters, &c.

Pedestals consist of three principal parts, the base, the die, and the cornice. No particular proportions can be assigned for them; but it is common to give them from one-third to one quarter of the height of the column and entablature, which being divided into nine parts, two are for the base, one for the cornice, and six for the die, which is of equal dimensions with the plinth of the column. One pedestal is sufficient for two columns placed together, and a continued pedestal with projections in the cornice, under each column, must be used for a colonnade or peristyle.

Pilasters follow in their parts the orders of columns, and admit of a like diminution, but are square instead of round in their plan.

Pilasters are employed in internal decorations to save room, and seldom project beyond the solid wall, above one quarter of their diameter; and sometimes they are seen on the external part of buildings alone, and also with columns. When placed behind, and very

near columns they need not project above one eight part of their diameter.

Attics.—In Athens, where it was for many ages a rule to conceal the roofs of buildings, attics had their origin. A line of low columns and pedestals, or of columns and balusters, may be employed for this purpose. They should be less in height than one-third of the order in which they are placed, but not lower than one-quarter. If the attic is composed of a low order, the base and cornice may have the same mouldings as the pedestals of the columns, and with the die, bear the same proportion to each other; and when they form pilasters over the columns of the building, the breadth of the bases must not exceed the upper diameter of the columns which they surmount.

Caryatides.—Representations of the human figure, the male called Persians, and the female Carians, or Caryatides, have been employed to support the entablatures of buildings. These were invented and used in memory of the captivity of the Persians and Carians by the Anthenians. The Persians may be of any size, with a Doric entablature, bearing the same proportion to the figure as to columns of the same height; but the Caryatides, or female figures, ought to have Ionic or Corinthian entablatures, and not to be larger than life.

Gothic Architecture.

Gothic is a general term for that architecture which was formerly used in England and on the continent. But the ancient buildings in this country are more accurately divided into *Saxon, Norman,* and *Saracenic.* When the Romans invaded Britain, they found no places corresponding with our ideas of a city, or town. Dwellings, like those of the ancient Germans, were scattered over the country, and generally situated on the brink of a rivulet, for the sake of water, or on the skirt of a wood or forest, for the purpose of hunting and providing for their cattle. These inviting circumstances being more conspicuous in some parts of the country than in others, the princes and chiefs selected the most agreeable spots for their residence.

When the Romans began to form settlements and colonies in this island, a sudden and remarkable change took place in the style of architecture. They not only built a considerable number of solid, convenient, and magnificent edifices for their own accommodation but also exhorted and instructed the Britons to follow their example. Soon after this, however, architecture, and the arts connected with it, began sensibly to decline in Britain. This arose, perhaps, partly from the building of Constantinople, which attracted the most celebrated architects to the east; but the almost total ruin and neglect of architecture in this island, may doubtless be attributed to the final departure of the Romans. The natives, and the descendants of Roman and British parents, having neither skill nor courage to defend their numerous towns, forts, and cities, suffered them to be plundered and destroyed by their ferocious invaders, the Scots, Picts, and Saxons; who, having no taste for the arts, committed the most wanton and extensive devastations.

The *Saxon* architecture was the Roman architecture in a decayed state. The Saxons having the Roman buildings continually before their eyes, employed workmen to build their edifices in a similar manner.

The characteristics of Saxon architecture, are, the semi-circular arch, and short, thick, massive columns. It has no pinnacles or pointed ornaments, no delineations of arms, nor statues, except in relief. The best specimen of this style is the north transept of Winchester Cathedral.

The *Norman* architecture differs from the Saxon chiefly in its increased proportion, and in the magnitude and massiveness of its buildings. arches highly ornamented with figures of angels, fruit, animals, &c.—Subjects serious and ludicrous promiscuously blended together walls without buttresses, arches supported by solid, clumsy pillars, with a regular base and capital; the capitals adorned with carvings of foliage and animals; the columns with small half columns joined to them, the surfaces ornamented with spirals, squares, network, and figures in relievo.

Saracenic or *Gothic Architecture,* the marks of which are its numerous and prominent buttresses, its lofty spires and pinnacles, its large and ramified windows, its ornamented niches and canopies, the sculptured saints and angels, the delicate lace-work of its fretted roofs, and an indiscriminate profusion of ornaments. But its most distinguishing characteristics are the small clustered pillars; and pointed arches, formed by the segments of two intersecting circles.

Florid Gothic. On the death of Eleanor, wife of Edward I. in 1290, this monarch, to show respect to the memory of his queen, caused a magnificent cross to be erected at every spot, where her body and the funeral procession halted. Most of these crosses have since been destroyed;—they were profusely decorated with sculptured ornaments. Those at Northampton, Geddington, and Waltham, are the most perfect which yet remain. This kind of workmanship was particularly adapted, by its richness, for screens and altar-pieces, and the lesser parts of the Gothic structure. Elaborate canopies, ornamented pinnacles, and octagonal niches and stalls were introduced, with the crocket ornament stealing up the angle, till the pyramidal point was crowned with a larger flower, or pine-apple,—while pendant decorations of fruits, flowers, and emblazonry were seen in all parts. Sculptures of small imageries were introduced in the fretted roofs of the principal aisles and chancel.

Modern Architecture.

Gothic architecture began to decline from the time of Henry VIII. A style in which the Grecian and Gothic were mixed together then prevailed, but in the sixteenth and seventeenth centuries the chaste architecture of the Greeks and Romans was revived. The first improvements took place in Italy, whence they passed into other parts of Europe; and though the Italians were long accounted the first architects, England produced Inigo Jones and Sir Christopher Wren, who hold the most exalted station.

The banqueting-house at Whitehall queen Katherine's chapel at St. James's; the piazza of Covent Garden, and many other public

buildings are monuments of the taste and skill of Inigo Jones.

The churches, royal courts, stately halls, magazines, palaces, and public structures designed by Sir Christopher Wren, are proud trophies of British talent. If the whole art of building were lost, it might be again recovered in the cathedral of *St. Paul*, and in that grand historical pillar called the *Monument*. To these we superadd *Greenwich Hospital, Chelsea Hospital, the Theatre at Oxford, Trinity College Library, and Emmanuel College, Cambridge;* the churches of *St. Stephen in Walbrook, St. Mary-le-bow, and* FIFTY-TWO *others in London*, serve to immortalize his memory. While we contemplate these, and many other public edifices erected and repaired under his direction, we are at a loss which most to admire—the fertile ingenuity, or the persevering industry of the artist.

The architectural history of the eighteenth century differs from that of preceding ages in two essential circumstances.

1. The *public* buildings, erected during this period, are, in general, not so grand and massive as those of some former periods. But while they fall short of splendour and magnificence, they are superior to most ancient structures in simplicity, convenience, neatness, and elegance.

2. *Private Dwellings* have been made more spacious, convenient, and agreeable to a correct taste, than in any preceding period. The liberal use of *glass*, in modern buildings, contributes greatly to their beauty and comfort, and is a point in which the ancients were totally deficient. In descending to the various minute details of human dwellings, especially those which have reference to elegance and enjoyment, it is obvious the artists of the eighteenth century exceed all others.

ARCTIC, in astronomy, an epithet given to the north pole; and likewise to a circle of the sphere, parallel to the equator, and 23 degrees 28 minutes distant from the north pole.

ARCTIUM, the *burdock*, in botany, a genus of the syngenesia polygamia æqualis class of plants; the common calyx of which is globose and imbricated; the compound flower is tubulated and uniform, with equal hermaphrodite corollulæ: the proper flower is monopetalous and tubulous, with a slender and very long tube; there is no pericarpium; the cup is connivent, and the seed single, vertically pyramidical, and crowned with a simple down shorter than the seed. There are two species; *viz.* the Laffa and Bardana.

ARCTOMYS, the *marmot*, a genus of quadrupeds differing very little from that of mus. The generic character is; front teeth two in each jaw, strong, sharp, and cuneated; grinders in the upper jaw, five on each side; in the lower jaw four; clavicles or collar bones perfect. They are diurnal animals; feed on roots, grain, and fruits, which they often collect in heaps. They reside in subterraneous holes, and become torpid in the winter. The head is gibbous, or rounded, with short ears, or none; body thick; tail short; hairy; fore feet four-toed, with a very short thumb; hind feet five-toed; cœcum large. There are eleven species, of which the following are the most remarkable. 1. Arctomys marmota, or Alpine marmot: ears short, round; body brown, beneath reddish. It inhabits dry open places, on the summits of the Alps and Pyrenees; feeds naturally on roots, herbs, and insects; when tamed it will eat any thing that is offered; drinks little; basks in the sun; lives among small tribes, with a centinel placed to give notice of danger, which is done with a hiss; forms a burrow with many chambers and entrances, for the summer; another lined with soft grass, in which it remains torpid during winter; it eats with its fore paws; walks on its heels, often erect; is easily caught when out of his burrow; in a tame state very destructive of food, clothes, furniture, &c.; and in winter kept awake with difficulty, even in warm rooms. 2. Marmot Quebec, is rather larger than a rabbit, with short ears and a round head. It inhabits Hudson's Bay and Canada. 3. Monax, or Maryland marmot, is found in various parts of North America, and in its habits and manners resembles that already noticed. The marmot when taken young may be easily domesticated, and is often taught to play numerous monkey-like tricks. 4. Arctomys Bobac, or grey marmot, this species is of the size of the Alpine marmot, and is found in Poland, Russia, and among the Carpathian hills. 5. Citillus, or variegated marmot, is the most beautiful of all the species. It inhabits Bohemia and other parts of Germany, from the banks of the Wolga to India and Persia, through Siberia and Great Tartary to Kamschatka, and even the continent of America. It is not certain that these sleep in the winter, like others of the Arctomys genus. They breed in the spring, and produce from five to eight at a time. They are said to be irascible and quarrelsome among themselves, and their bite is very severe. They feed not only on animal food, but on small birds and other animals, which they will kill. They are easily tamed, and will grow familiar in a few days. They [illegible] extremely clean, and after feeding, generally wash their faces, and clean their fur.

ARCTOPUS, in botany, a genus of the polygamia diœcia class of plants, the general umbel of which is long and unequal; the partial umbel is shorter; the involucra consist of five leaves; the corolla of five petals; the fruit is single and bilocular, and stands under the receptacle of the floscule; the seed is single, cordated, and acuminated. There is but one species.

ARCTOTIS, in botany, a genus of the polygamia necessaria order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ discoites. The receptacle is bristly; the coror of the pappus is pentaphyllous; and the caly is imbricated with scales loose at the top There are 11 species; natives of Ethiopia, o the Cape of Good Hope.

ARCTURUS, a star of the first magnitud in the skirt of Bootes, so called from its bein near the tail of the bear. It is supposed to be the nearest fixed star to our system visible in the northern hemisphere.

ARDEA, the HERON, a genus of the order of grallæ. The general characters of this order are: the bill is straight, sharp, long, and compressed, with a furrow from the nostrils to the point; the nostrils are linear, and the feet have four toes. Under this genus Lin

næus comprehends the grus or crane, the ciconia or stork, and the ardea or heron. There are 79 species, of which the following are the most remarkable.

1. Ardea Americana, or hooping crane of Edwards, is a native of America. The crown of the head and temples are naked and papillous; the forehead, nape of the neck, and prime wing feathers, are black, but the body is white. They lay two white eggs, and sit 20 days.

2. Ardea argil, or hurgil, of Ives, is a very large species; from tip to tip of the wings, measuring 14 feet 10 inches, and from the tip of the bill to the claws 7 feet and a half; the bill is 16 inches round at the base, of different colours, and of a triangular shape; the feathers of the back and wings are of an iron colour, those of the breast long; over the belly a great deal of down, of a dirty white; the legs and half the thighs are naked; the naked parts full three feet in length. This monster inhabits Bengal. On opening one of these, a terapin, or land-tortoise, 10 inches long, was found in its craw, and a large male black cat was found entire in its stomach.

3. Ardea ciconea, or white stork of Ray, has naked eye-balls, and black prime winged feathers. The skin below the feathers, as also the beak, feet, and claws are of a blood-colour. It is a native of Europe, Asia, and Africa, and feeds upon amphibious animals. It is such an enemy to serpents, that it is reckoned almost a crime to kill a stork. From this favourable treatment, they are seen in Holland and the Low Countries walking unconcerned in the middle of the streets.

4. Ardea garzetta, or egret, is crested behind; the body is white, the beak black, and the feet greenish. It is a most elegant bird. It weighs about one pound, and the length is 24 inches, to the end of the legs 32. It is a native of the East; but was once common in Britain.

5. Ardea grus, or common crane, has a naked papillous crown; the prime feathers of the wings are black; the body is ash-coloured. This species is met with in great flocks throughout northern Europe and Asia. They feed on reptiles of all kinds, as well as on green corn.

6. Ardea herodias, or cristata maxima of Catesby, is crested behind, has a dusky-coloured back, reddish thighs, and the breast speckled with black. It is four feet and a half when erect: is a native of Virginia, and feeds upon fish, frogs, lizards, &c.

7. Ardea leucogeranos of Pallas, or the Siberian crane of Pennant, is four feet and a half when erect. The bill is red, the irides are white; the plumage is white as snow, except the ten first greater quills, with the coverts of them which are black; the legs are long and red. This species inhabits the marshes and lakes in Siberia. It makes its nest among the reeds, and lays two ash-coloured eggs, spotted with brown.

8. Ardea major, or common heron, has a black crest depending from the back part of the head, an ash-coloured body, and a black line on the neck and breast. It is a native of Europe. It builds in trees, and sometimes in high cliffs near the sea, commonly in company with others, like rooks. It was formerly in this island game; heron-hawking being a favourite diversion of our ancestors.

9. Ardea pavonia, or the crowned crane, has an erect bristly crest, with the temples and two wattles naked. It is a native of the coast of Guinea, and remarkably tame.

10. Ardea stellaris, or the bittern, has a smooth head, and is varigated through the body with dark coloured spots of different sizes. It is a native of Europe and inhabits the fen countries. It flies principally about the dusk of the evening, and rises by a spiral ascent, till it is quite out of sight. The food of the bittern is chiefly frogs. Its flesh has the flavour of the hare, and nothing of the fishiness of that of the heron.

11. Ardea violacea, or crested bittern of Catesby, has a white crest; the body is variegated with black and white, and bluish below. These birds are found in Carolina during the rainy seasons, and are called crab-catchers.

12. Ardea virgo has a straight greenish bill and crimson irides. The crown of the head is ash-coloured; the rest of the head, the upper and all the under parts, to the breast, black: the back, and all the under part from the breast, of a bluish ash-colour; behind each eye springs a tuft of long white feathers, which decline downwards. It is found in many parts of Asia and Africa.

ARECA, in botany a genus of plants, the characters of which are not perfectly ascertained; the calyx of the male flower is a bivalve spatha, the spadix is ramose; the corolla consists of three acuminated petals; the stamina are nine filaments, of which the three exterior ones are the longest; the female flowers are in the same spadix and spatha; the corolla is like the male corolla; the fruit is a sub-oval fibrose drupe surrounded at the base with an imbricated calyx, and containing an oval seed.

There are three species, of which the oryzæformis is the cabbage-tree of the East Indies. The oleracea is found in the West Indies, the green tops of which are cut and eaten as a cabbage.

ARENA, among the Romans, was a place where the gladiators fought; and was so called from being strewed with sand, for the purpose of concealing from the view of the spectators, the blood spilt in the combats.

ARENARIA, *sand-wort*, in botany, a genus of the decandria trigynia. Calyx five-leaved, spreading; petals five, entire; capsule superior, one-celled, many seeded. There are 36 species.

ARENARIUS, the name of a book of Archimedes, in which is demonstrated, that not only the sands of the earth, but even a greater quantity of particles, than could be obtained in the immense sphere of the fixed stars, might be expressed by numbers, in a way invented and described by himself.

AREOPAGUS, or ARÆOPAGUS, in Grecian antiquity, a sovereign court at Athens, so famous for the justice and impartiality of its decrees, that the gods themselves are said to have submitted their quarrels to its determination.

ARETHUSA, in botany, a genus of the gynandria diandria class; and in the natural method ranking under the seventh order, orchideæ. The generic character is taken from the nectarium, which is tabular, situated at the bottom of the corolla, and the inferior labium

fixed to the stylus. There are seven species, all natives of America.

ARETIA, in botany, a genus of the pentandria monogynia class; and in the natural method ranking under the 21st order, preciæ. The corolla is divided into five parts; the tube of the corolla is ovated; and the capsule is globular, and consists but of one cell. There are three species.

ARGENT, in heraldry, the white colour in the coats of gentlemen, knights, and baronets; the white in the arms of the sovereign princes is called luna, and that in the arms of the nobility, pearl: this is expressed in engraving, by the parts being left plain, without any strokes from the graver. See HERALDRY.

ARGONAUTA, in natural history, a genus of worms, of the order testacea. Animal a sepia or clio; shell univalve, spiral, involute membranaceous, one-celled. There are five species. A. argo has the keel, or ridge of the shell slightly toothed on each side; it inhabits the Mediterranean and Indian oceans, and is the famous nautilus, supposed in the early ages of society to have first taught men the use of sails. When it means to sail it discharges a quantity of water, by which it is made lighter than the sea, and rising to the surface, erects its arms and throws out a membrane between them, by which means it is driven forward like a vessel under sail; two of the arms it hangs over the shell, to serve as oars or a rudder. The shell is white or yellowish, with smooth or knotty striæ, or ribs, which are sometimes forked; the keel is generally brownish.

ARGUMENT, ARGUMENTUM, in rhetoric and logic, an inference drawn from premises, the truth of which is indisputable, or at least highly probable.

ARGUMENT, in astronomy, denotes a known arch, by means of which we seek another one unknown.

The argument of the moon's latitude is her distance from the node; and the argument of inclination is an arch of a planet's orbit, intercepted between the ascending node and the place of the planet from the sun, numbered according to the succession of the signs of the zodiac.

ARGUS-SHELL, a species of porcelain-shell, beautifully variegated with spots resembling, in some measure, those in a peacock's tail.

ARGYTHAMNIA, in botany, a genus of the class and order monoecia tetrandria; the essential character is, male cal. four-leaved; cor. four-petalled; fem. cal. five leaved, cor. none, styles dichotomous, caps. nicoceous, solitary seeds. There is one shrubby species, a native of Jamaica.

ARIES, in astronomy, a constellation of fixed stars, drawn on the globe in the figure of a ram. It is the first of the twelve signs of the zodiac, from which a twelfth part of the ecliptic takes its denomination. It is marked thus ♈, and consists of sixty-six stars.

ARISTA, among botanists, a long needle-like beard, which stands out from the husk of a grain of corn, grass, &c.

ARISTOLOCHIA, BIRTHWORT, a genus of the hexandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. It has no calyx; the corolla consists of one entire petal; and the capsule, which is below the flower, has six cells. There are 27 species, mostly foreign.

ARITHMETIC, *theoretical*, is the science of the properties, relations, &c. of numbers, considered abstractedly, with the reasons and demonstrations of the several rules. Euclid furnishes a theoretical arithmetic, in the seventh, eight, and ninth books of his Elements.

ARITHMETIC, *practical*, is the art of numbering or computing; that is, from certain numbers given, of finding certain others, whose relation to the former is known. As, if two numbers, 10 and 5, are given, and we are to find their sum, which is 15, their difference 5, their product 50, their quotient 2.

A treatise on arithmetic without numerous examples for practice under each rule, could be of little or no use in a work of this description. And as the limits to which we are necessarily confined expressly forbid the introduction of such an article, we shall confine our observations to a few particulars that will, we doubt not, be found of essential service to those who are employed in teaching, as well as to those who are studying this important branch of mathematical science.

And first, let it be observed, that as no person can ever rise to eminence, either in science or in the various departments of commerce, without being an expert practical arithmetician, it is of the utmost consequence that a broad and solid foundation be laid in the introductory parts of this branch of knowledge. Before the pupil proceeds to the simplest operations in addition he ought to practise numeration until he can, without difficulty, read lines of figures of considerable length. These the teacher ought to vary according to the progress of the scholars. The most effectual method of conducting this process is to write the lines of figures with chalk, on a board painted black, which ought to be suspended on the wall at a convenient height, and the pupils, being ranged in order before it, should, in succession, read the whole. At first, the lines should be divided into the proper periods by pointing; but after a little practice this will be found to be unnecessary. When the pupils have become expert in notation, let them proceed to simple addition, which may be taught with the most effect, and in the least time, by a similar process. It will be found of great advantage for each of the scholars to copy from the board, on his own slate, the examples exhibited for practice, which should consist of as many figures as can be conveniently and distinctly arranged on one side of a common sized slate. In writing down these examples for the exercise of his pupils, the teacher will find it of importance so to place the figures that those which are the most difficult to be added may come together. After the same manner the rules of subtraction, multiplication, and division, may be taught, but the pupil ought, on no account, to leave any rule until he can with ease perform the most difficult examples that can be proposed to him under it. When the four rules above mentioned have been acquired in their simple form, the pupils should be taught the use of the arithmetical signs, and, for some time, exercised in promiscuous examples which involve their application to the extent of the progress they have made in these rules.

Proceeding thus through the first four rules in their application to compound quantities, the young arithmetician will find himself fully prepared to enter on the rules of proportion, practice, interest, &c.: and, understanding what he is engaged in, will be delighted with the results of his own operations; and what is of still greater consequence, will speedily become qualified to transact the business of the counting-house with accuracy and dispatch.

Various expedients have been devised for preventing youth in schools from the too frequent practice of employing their school-fellows, for a trifling reward, to perform their arithmetical calculations for them; but the plan here recommended has been found by experience to be the most effectual. It is, indeed, attended with more personal labour, on the part of the master, than either rewards or punishments; but for this he is amply repaid by the pleasure of witnessing the progress of even the dullest and the idlest of his pupils.

With respect to the most suitable works on arithmetic to be put into the hands of young persons, it may be observed, that almost any one of those now in general use will, with the assistance of a good teacher, answer the end proposed. Perhaps, for common purposes, the late editions of Walkinghame's "Tutor's Assistant," which are much improved, will be found sufficient. Dr. Hutton's, and Mr. Bonnycastle's works on this subject are entitled to high commendation, and may be perused with great advantage by those who desire to obtain a knowledge of the more difficult operations in arithmetic; but in this respect Keith's "Complete Practical Arithmetician" stand's unrivalled.

If the student is desirous of prosecuting vulgar and decimal arithmetic to their utmost extent, and in their application to annuities, mensuration, gauging, &c. he will find ample satisfaction from the excellent work of Mair: and if an historical and philosophical acquaintance with the subject be required, Professor Leslie's "Philosophy of Arithmetic," will be found to yield much curious and valuable information.

There is an excellent work on arithmetic for the use of schools, by the late Rev. J. Joyce, who recommends the teaching of fractions and logarithms along with the simpler parts of vulgar arithmetic; and certainly no good reason can be shewn why this plan should not to be adopted, since with proper explanation, they may be rendered perfectly simple. But whatever treatise may be adopted, it is recommended as an indispensable requisite to general success, that the pupils be frequently exercised in promiscuous examples, and at stated periods, examined on the arithmetical tables, which they ought to commit to memory.

ARITHMETICAL *complement of a logarithm*, the sum or number which a logarithm wants of 10,000000: thus the arithmetical complement of the logarithm 8.154032 is 1.845968.

ARMORY is a branch of the science of heraldry, consisting in the knowledge of coats of arms, as to their blazons and various intendments.

ARMOUR denotes all such habiliments as serve to defend the body from wounds, especially of darts, a sword, a lance, &c. A complete suit of armour formerly consisted of a helmet, a shield, a cuirass, a coat of mail, a gauntlet, &c. all now laid aside.

ARMS, in general, all kinds of weapons, whether used for offence or defence.

ARMY, a number of soldiers, consisting of horse and foot, provided with artillery, &c. under the command of a general, having lieutenant-generals, major-generals, brigadiers, and other officers under him. An army consists of squadrons and battalions, and is usually divided into three corps, and formed into three lines: the first line is called the van-guard, the second the main body, the third rear-guard, or body of reserve. The middle of each line is occupied by the foot: the cavalry forms the right and left wing of each line; and sometimes squadrons of horse are placed in the intervals between the battalions. When the army is drawn up in order of battle, the horse are placed at the distance of five feet from each other, and the foot at three. In each line the battalions are distant from each other about 180 feet, which is nearly equal to their length in front; and the same holds with regard to the squadrons, which are about 300 feet distant, the extent of their own front.

ARNOPOGON, a genus of the syngenesia æqualis class and order. Receptacle naked; down feathery, on a pedicel; calyx one-leafed, eight-parted, turbinate. There are four species.

AROMA, is that part of odorous bodies which affects the organs of smell, and is supposed by some to be a peculiar principle.

ARRAC, a spirituous liquor imported from the East Indies, and obtained by distillation from rice or sugar, fermented with the juice of cocoa-nuts.

ARRAIGNMENT, in law, the arraigning or setting a thing in order; as a person is said to arraign a writ of novel disseisin, who prepares and fits it for trial. It is most properly used to call a person to answer in form of law upon an indictment, &c. at the suit of the king.

ARREST, the apprehending and restraining a person, in order to oblige him to be obedient to the law; which in all cases, except treason, felony, or breach of the peace, must be done by virtue of a precept out of some court. Outer doors may be broken open to arrest a felon; but in civil cases it is otherwise, unless it is in pursuit of one before taken.

ARRONDE'E, in heraldry, a cross, the arms of which are composed of sections of a circle: not opposite to each other, so as to make the arms bulge out thicker in one part than another; but the sections of each arm lying the same way, so that the arm is everywhere of an equal thickness, and all of them terminating at the edge of the escutcheon like the plain cross.

ARSENAL, in military affairs, in a large and well fortified town, is a spacious building, in which are deposited all kinds of arms, and other warlike implements such as cannon, mortars, howitzers, small arms, and every other warlike kind of engines and instruments of death.

ARSENIC, is generally found in combination with sulphur, oxygen, and many of the metals. When reduced to its pure metallic

state, it is a friable, brilliant metal, of a bluish white colour, easily tarnishing, that is, oxydizing, by exposure to the air. In all its states it is poisonous. Arsenic is used to whiten copper, and it enters into most of the compositions for the specula of reflecting telescopes and for other optical purposes. Its oxyds are employed in many processes of the dyer, also as fluxes for glass, and in several of the arts. The sulphurets of arsenic form valuable pigments of different colours.

ART *and Part*, in the law of Scotland, is applied to an accomplice.

The facts inferring art and part need not be particularly laid in the libel or indictment, for these general words, as terms of stated signification, are sufficient. Yet these facts may be set forth, and it is proper so to do, if the prosecutor chooses to confide in the court rather than in the jury. Also in the criminal letters, the persons of the accomplices must be described by proper names and designations.

ARTEDIA, a genus of the digynia order, and pentandria class of plants, in the natural method ranking under the 45th order, umbellatæ. The involucra are pinnatifid: the floscules of the disc masculine; and the fruit is hispid with scales. There is but one species.

ARTEMISIA, MUGWORT, SOUTHERNWOOD, and WORMWOOD, a genus of the polygamia superflua order, and syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ nucamentaceæ. The receptacle is either naked or a little downy; it has no papus; the calyx is imbricated with roundish scales; and the corolla has no radii. These are 44 species, of which the following are the most remarkable.

1. Artemisia abrotanum, or southernwood, which is kept in gardens for its agreeable scent.

2. Artemisia absinthium, or common wormwood, grows naturally in lanes and uncultivated places.

3. Artemisia arborescens, or tree-wormwood, grows naturally in Italy and the Levant, near the sea. It rises six or seven feet high, sending out many ligneous branches.

4. Artemisia dracunculus, or tarragon, is used in sallads, especially by the French, and is a hardy plant, spreading by creeping roots.

5. Artemisia maritima, or sea wormwood, grows on the sea-coasts where there are several varieties.

6. Artemisia Pontica, or Pontic wormwood, is a low herbaceous plant; the stalks die in autumn, and new ones appear in spring.

7. Artemisia santonicum, produces the semen santonicum, which is used for worms in children. It grows in Persia, whence the seeds are brought to Europe.

8. Artemisia vulgaris, or common mugwort, grows naturally on banks and by the sides of foot-paths in many parts of Britain.

ARTERY, in anatomy, a conical tube or canal, which conveys the blood from the heart to all parts of the body. See ANATOMY.

ARTICHOKE. See CYNARA.

ARTICLE, in grammar, a particle, in most languages, that serves to express the several cases and genders of nouns, when such languages have not different terminations to denote the different states and circumstances of nouns. The Latin language has no articles; but the Greek has the article ὁ; the English, the articles *a* and *the*; the French lanugage has three articles, viz. *le*, *la*, and *les*; the Italian, *il*, *lo*, and *la*; and the German, *der*, *das*, and *dat*.

ARTICULATION, in anatomy, denotes the juncture of two bones intended for motion: there are two kinds, one called diarthrosis, the other synarthrosis, the former has a manifest, the latter only an obscure motion.

ARTIFICERS, are persons employed to work with the hands, and to manufacture any kind of commodity in iron, brass, wood, &c. Artificers are the same with what we term handicrafts and mechanics.

ARTILLERY, in the most appropriate application of the word, means the cannon, mortars, howitzers, and other large pieces, for discharging shot and shells by the expansive force of inflamed gunpowder, as used in the land service. In a more enlarged sense the word denotes engines of war of all sorts, ancient and modern, by which darts, stones, bullets, &c. were shot forth in battle.

By artillery is also meant, the science which all officers of artillery ought to possess. This science teaches the knowledge of the materials and ingredients that enter into the composition and structure of whatever relates to the artillery; the construction, &c. of the different engines of war; the arrangement, movement and management of cannon, in the field, or in sieges; and the best method of operation with the whole train taken together.

ARTILLERY, *flying*, a species of it, called so from the celerity with which it is moved from station to station.

Seats are contrived in the carriage and limbers of guns of this sort for the men who work it, and a sufficient number of horses are added to carry the whole at a gallop, when the ground will admit of this pace. Each horse is in general rode by a separate driver, and the men are all trained either to drive or work the gun, as occasion may require.

Flying artillery were first used by the French, shortly after their revolution, and materially assisted them in some of their most signal victories. Their use has now become general in Europe.

ARTOCARPUS, (from *αρτος*, bread and *καρπος*, fruit,) the BREAD-FRUIT TREE, a genus of the monandria order, belonging to the monœcia class of plants. It has a cylindric amentum or catkin, which thickens gradually, and is covered with flowers: the male and female in a different amentum. In the male, the calyx is two-valved, and the corolla is wanting. In the female, there is no calyx or corolla: the stylus is one, and the drupa is many-celled. This remarkable tree, according to the statements of Cook, Anson, and others, seems to supply the inhabitants of the places where it is cultivated with their principal article of food. It abounds in the South Sea Islands, and grows to about the size of our largest apple trees. The fruit hangs on the branches like apples, and is larger than a cocoa-nut, with a thick tough rind, and when ripe it turns yellow. It is gathered before it becomes quite ripe, and baked till the crust be-

comes quite black; when this is rasped off, there remains a loaf of bread, and the crumb is as soft and sweet as a new-baked roll. The bread-fruit tree was introduced into the West Indian Islands in the year 1793, by order of the British Government. This tree not only supplies food, but also clothing, for the bark is stripped off the suckers, and formed into a kind of cloth. To procure the fruit for food costs the Otaheiteans no trouble or labour but climbing a tree; which though it should not indeed shoot up spontaneously, yet, as Captain Cook observes, if a man plant ten trees in his life time, he will as completely fulfil his duty to his own and future generations, as the native of our less temperate climate can do by ploughing in the cold winter, and reaping in the summer's heat, as often as these seasons return; even if after he has procured bread for his present household, he should convert a surplus into money, and lay it up for his children.

ARTS, are usually divided into liberal and mechanical; the former comprehend poetry, painting, sculpture, architecture, &c.: the latter take in carpentry, masonry, &c. The *fine arts* seem to be a term adopted from what the French call *beaux arts*, which are, painting, engraving, sculpture, music, &c.

ARUM, WAKEROBIN, or CUCKOW-PINT, in botany, a genus of the polyandria order, belonging to the gynandria class of plants, and in the natural method ranking under the 2d order, piperitæ. The spatha is monophyllous, and cowl-shaped: the spadix is naked above, female below, and stamineous in the middle. There are 32 species, of which the most remarkable are the following:

1. Arum arborescens, or dumb cane, a native of the Sugar Islands and America. It has an acid juice. 2. Arum arisarium, as well as the arum proboscidium and arum tenuifolium, are all denominated friar's-cowl, from the shape of the flowers, which appear in April. 3. Arum colocasia; this, with the arum divaricatum, esculentum, peregrinum, and sagittifolium, has mild roots, which are eaten in hot countries. The leaves of the esculentum called Indian kale, are also made use of where English vegetables are not to be had. 4. Arum divaricatum has spear-shaped leaves. 5. Arum dracunculus or common dragon, grows naturally in the southern parts of Europe. The stalk is straight, and about four feet in height, and spotted like a snake, the flower, which grows at the top of the stalk, has a long spathe of a dark purple colour. 6. Arum Italicum is a native of Italy, Spain, and Portugal: the leaves are above a foot long, very large, and veined with white, interspersed with black spots. 7. Arum maculatum, or common wake robin, grows in woods, and on shady banks, in most parts of Britain. The leaves are halbert-shaped, entire, and spotted; the berries numerous. It flowers in April. The receptacle is long and club-shaped, with the seed-buds surrounding the base. The chives are fixed to the receptacle among the seed-buds, between two rows of tendrils. 8. Arum trilobalum, or Arum of Ceylon, is a native of India. It is a low plant, and the flower which rises from the root, is of a fine scarlet colour. The roots of the maculatum and dracunculus are used in medicine as stimulants and attenuants. The latter is most powerful, and is of particular benefit in rheumatic complaints.

ARUNDELIAN *marbles*, called also the Parian Chronicle, are ancient stones, on which is incribed a chronicle of the city of Athens, supposed to have been engraven in capital letters, in the island of Paros, 264 years before Christ. They take their name from the earl of Arundel, who procured them from the East, or from his grandson, who presented them to the University of Oxford.

ARUNDO, in botany, the REED, a genus of the digynia order, and triandria class of plants, and in the natural method ranking under the fourth order, gramina. The calyx consists of two valves, and the floscules are thick and downy. There are 14 species; the most remarkable are:

1. Arundo bambos, or the bamboo, a native of the East Indies and some parts of America; where it frequently attains the height of 60 feet. The main root is thick, jointed, and sends out many fibres, of a whitish colour, and many feet long. The flowers resemble those of the common reed. The young shoots are covered with a dark green bark; these when very tender afford a pickle which is esteemed a valuable condiment in the Indies. The stalks in their young state are almost solid, and contain a milky juice: but as they advance in age they become hollow, except at the joints, where they are stopped by a woody membrane, upon which this liquor concretes into a substance called tabaxir, or sugar of Mombu; which was held in much esteem by the ancients. The old stalks grow to five or six inches diameter, and are then of a yellow colour; and are so hard and durable, that they are used in buildings, and for making all sorts of household furniture; and when bored through the membranes of their joints, are converted into water-pipes. The smaller stalks are used for walking sticks; and the inhabitants of Otaheite make flutes of them.

2. Arundo donax, or cultivated reed, is a native of warm countries, but will bear the cold of our moderate winters in the open air. The stalks of these are used by weavers, as also for making fishing-rods.

3. Arundo orientalis is what the Turks use as writing pens; it grows in a valley near mount Athos, as also on the banks of the river Jordan.

4. Arundo phragmitis, or the common marsh-reed, grows by the sides of our rivers, and in standing waters.

5. The arundo versicolor, or Indian variegated reed, is supposed to be a variety of the donax, differing from it only in having variegated leaves.

AS, in antiquity, a particular weight, consisting of twelve ounces; being the same with libra, or the Roman pound.

As, was also the name of a Roman coin, which was of different matter and weight according to the different ages of the commonwealth.

It is also used to signify an integer, divisible into twelve parts, from which last acceptation it signified a whole inheritance.

ASAFŒTIDA, in chemistry, a gum resin obtained from ferula asafœtida, a perennial plant, which is a native of Persia. When the plant is about four years old, its roots are dug

up and cleaned, and from their extremity, when cut, a milky juice exudes, which soon hardens and constitutes asafœtida. It comes into this, and other countries in Europe, in small grains of different colours, hard and brittle. Its taste is acrid and bitter; its smell is strongly alliaceous and fetid. Alcohol dissolves three-fourths of this substance, and water takes up about one-fourth, if applied before the spirit. It yields an oil when distilled with water and alcohol. The specific gravity is 1.32.

ASARUM, Asarabacca, a genus of the monogynia order, belonging to the dodecandria class of plants. The calyx is trifid or quadrifid, and rests on the germen; there is no corolla; the capsule is leathery and crowned. There are three species, viz.

1. Asarum Canadense, a native of Canada. 2. Asarum Europæum, grows naturally in some parts of England. Asarum Virginicum, a native of America, has no remarkable properties.

The principal use of this plant among us is as a sternutatory.

ASBESTOS, a mineral substance of which there are five varieties, all more or less flexible.

1. *Amianthus,* occurs in fine, long, flexible, elastic fibres, of a white, greenish, or reddish colour. It is somewhat unctuous to the touch, and is slightly translucent. It melts with difficulty before the blowpipe into a white enamel. The ancients manufactured cloth from the fibres of asbestos, for the purpose, it is said, of wrapping up the bodies of the dead when exposed on the funeral pile. 2. Common asbestos occurs in masses of fibres of a dull greenish colour, and of a pearly lustre. 3. *Mountain Leather,* consists of fibres interwoven and interlaced so as to become tough; its colour is yellowish white. 4. *Mountain Cork,* or *elastic* asbestos, is opaque, has a meagre feel and appearance, not unlike cork, and is somewhat elastic. It swims on water; colours—white, grey, and yellowish brown. 5. *Mountain Wood,* Ligniform asbestos. It is usually brown, and has the appearance of wood. Although the cloth of asbestos, when soiled, is restored to its primitive whiteness by heating in the fire, yet it is found to lose a little of its weight by such treatment. Asbestos is found in Crete, Cyprus, Tartary, Egypt, the Island of Anglesea, and in some parts of Scotland.

ASCARINA, in botany, a genus of the diœcia monandria class and order. Ament filiform; no corolla. Male, anthera worm-shaped, four-grooved: female, stigmata three-lobed: drupe. One species, in the Society Isles.

ASCENSION, in astronomy, the rising of the sun or a star, or any part of the equinoctial with it, above the horizon: is either right or oblique.

Right ascension is that degree of the equator, reckoned from the beginning of Aries, which rises with the sun or a star, in a right sphere.

Oblique ascension is that degree and minute of the equinoctial, counting from the beginning of Aries, which rises with the centre of the sun or a star, or which comes to the horizon at the same time as the sun or star, in an oblique sphere.

ASCENSIONAL *difference,* the difference between the right and oblique ascension in any point of the heavens; or it is the space of time that the sun rises or sets before or after six o'clock.

ASCIDIA, in natural history, a genus of worms, of the order mollusca. Body fixed, roundish, and apparently issuing from a sheath: two apertures, generally placed near the upper end, one beneath the other. There are more than 40 species found in the sea, adhering by their base to rocks, shells, and other submarine substances. They are more or less gelatinous, and have the power of squirting out the water which they take in.

ASCII, among geographers, an appellation given to those inhabitants of the earth, who, at certain seasons of the year have no shadow: such are all the inhabitants of the torrid zone, when the sun is vertical to them.

ASCLEPIAS, *swallow-wort,* in botany, a genus of the pentandria digynia class of plants, the calyx of which is a permanent perianthium, divided into five acute and small segments; the corolla consists of a single petal, divided into five deep segments at the mouth; and its fruit consists of two follicles or vaginæ, containing a great number of imbricated seeds, winged with down. There are about 40 species.

ASCYRUM, *Peter's wort,* in botany, a genus of the polyandria order, and polyadelphia class of plants: in the natural method ranking under the twentieth order, rotaceæ. Calyx four-leaved, corolla four-petalled; filaments numerous, and having four boundaries. There are three species, 1. Ascyrum crux Andreæ. 2. Ascyrum hypericoides. 3. Ascyrum villosum: they are natives of the West Indies.

ASH. See Fraxinus.

ASHES, the earthly part of wood and other combustibles after being consumed by fire. All kinds of ashes contain an alkaline salt, and are excellent manure for cold wet grounds. They are also of use in making lixiviums or lyes for bleaching, &c.

ASPALATHUS, *African Broom:* a genus of the decandria order, and diadelphia class of plants; in the natural method ranking under the 32d order, papilionaceæ. The calyx consists of 5 divisions; the pod is oval, and contains 2 seeds. Of this genus there are 37 species; all natives of warm climates, and must be preserved in stoves by those who would cultivate them here. The rose wood, whence the oleum Rhodii is obtained, is one of the species.

ASPARAGUS, a genus of the monogynia order and hexandria class of plants; in the natural method ranking under the 11th order sarmentaceæ. The calyx is quinquepartite; the three inferior petals are bent outwards; the berry has three cells, and contains two seeds. There are 13 species; but the only one cultivated in the gardens is the common asparagus, with an upright herbaceous stalk, bristly leaves, and equal stipula. The other species are kept only for the sake of variety. The plants being raised from seed, after having acquired a period of three or four years' growth, produce proper sized asparagus, of which the same roots furnish an annual supply for many years, continuing to rise in perfection for six or eight weeks in the summer season, the shoots afterwards run up to stalks and flowers, and perfect seeds in autumn. But besides the crop raised in the summer season, it may also be obtained in perfection during the winter, and early in the spring, by the aid of hot-beds.

Asparagus is always three years at least,

from the time of sowing the seed, before the plants obtain strength enough to produce shoots of due size for the table; that is, one year in the seed-bed, and two after being transplanted, though it is sometimes three or four years after planting before they produce good full-sized shoots. But the same bed or plantation will continue producing good asparagus ten or twelve years, and even endure fifteen or twenty years. However, at that age the shoots are generally small, and the whole annual produce inconsiderable.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus (῾), and importing that the letters over which it is placed ought to be strongly aspirated, or pronounced as if an *h* was joined with them.

ASPERUGO, in botany, a genus of the pentandria monogynia class of plants, the flower of which consists of one rotated petal, divided into several segments at the limb; and its calyx, which is divided like the flower-petal, contains the seeds, which are four in number, and of a roundish compressed figure. There are two species.

ASPERULA, *woodruffe*, in botany, a genus of the tetrandria monogynia class of plants, the flower of which consists of one petal, divided into four segments at the limb; and its fruit is composed of two roundish, dry berries, adhering together, in each of which is a single seed of the same roundish shape. There are eleven species. The common sweet-scented woodruffe is a native of many parts of Europe, in woods and shady places. The scent is pleasant, and when dried, diffuses an odour like that of vernal grass.

ASPHALTUM. This substance, likewise called bitumen Judaicum, or Jew's pitch, is a smooth, hard, brittle, black or brown substance, which breaks with a polish, melts easily when heated, and when pure burns without leaving any ashes. It is found in a soft or liquid state on the surface of the Dead Sea, but by age grows dry and hard. The same kind of bitumen is likewise found in the earth in other parts of the world; in China; America, particularly in the island of Trinidad; and some parts of Europe, as the Carpathian hills, France, Neufchattel, &c. Its specific gravity, according to Boyle, is 1.400, to Kirwan, from 1.07 to 1.65. A specimen from Albania, of the specific gravity of 1.205, examined by M. Klaproth, was found to be soluble only in oils and in ether.

The Egyptians used asphaltum in embalming, under the name of mumia mineralis, for which it is well adapted. It was used for mortar at Babylon.

ASPHODEL, in botany, a genus of the hexandria monogynia class of plants, the flower of which is liliaceous, consisting of a single petal, divided into six segments; and its fruit is a globose-trilocular capsule, containing a number of triangular seeds, gibbous on one side. According to Martyn there are three species.

ASPLENIUM, *milt-waste*, or *spleen-wort*, in botany, a genus of cryptogamia filices plants, the fructification of which is arranged in clusters, and disposed in form of straight lines, under the disk of the leaf. This genus comprehends 47 species.

ASSAY. There are two kinds of assaying; the one before metals are melted, the other after they are struck; the first is to bring them to their proper fineness, and the last to see that they are standard. For the first the assayers used to take 14 or 15 grains of gold and half a dram of silver, if it be for money, and 18 grains of the one and a dram of the other, if for other uses. The second assay is made of one of the pieces of money, which is cut into four parts. The quantity of gold for an assay is here six grains. Assaying is also the particular mode of examining every ore or mixed metal according to its nature with the proper fluxes, in order to discover not only what metals and the proportions of them, are contained in ores, but also the quantity of sulphur, vitriol, alum, arsenic, and other matters. *Gold* is obtained pure by dissolving it in nitro-muriatic acid, and precipitating the metal by dropping in a diluted solution of sulphate of iron; the powder which precipitates is pure gold. *Silver* is obtained pure by dissolving it in nitric acid, and precipitating it with a diluted solution of sulphate of iron. With metallurgists, the interior or mass is supposed to consist of twenty-four imaginary parts, called *carats*. Gold of twenty-four carats, means *pure* gold; the number of carats mentioned specifies the parts of pure gold, and what that number *wants* of twenty-four carats, indicates the quantity of base metal in the alloy. Gold of twelve carats, means twelve parts of gold, and twelve of another metal. Gold coins of Great Britain are of twenty-two carats *fine*; they contain therefore eleven parts of gold and one of copper. *Parting* is the separation of gold from silver when both are contained in an alloy, and is founded on the *insolubility* of gold, and solubility of silver in nitric acid.

ASSIGN, in common law, a person to whom a thing is assigned or made over.

ASSIGNEE, in law, a person appointed by another to do an act, transact some business, or enjoy a particular commodity. Assignees may be by deed or by law; by deed, where the lessee of a farm assigns the same to another; by law, where the law makes an assignee, without any appointment of the person entitled, as an executor is assignee in law to the testator, and an administrator to an intestate. But when there is assignee by deed, the assignee in law is not allowed.

ASSIGNING, in a general sense, is the setting over a right to another; and in a special sense is used to set forth and point at, as to assign an error, to assign false judgment, to assign waste; in which cases it must be shewn wherein the error is committed, where and how the judgment is unjust, and where the waste is committed.

ASSIGNMENT, is a transfer, or making over to another, of the right one has in any estate; but it is usually applied to an estate for life or years. And it differs in a lease only in this; that by a lease one grants an interest less than his own, reserving to himself a reversion; in assignment he parts with the whole property, and the assignee stands in all respects in the room of the assignor.

ASSIMILATION, in physics, is that motion by which bodies convert other bodies related to them, or at least such as are prepared to be converted, into their own substance and nature.

ASSIZE, in old law books, is defined to be 'an assembly of knights and other substantial men, with the justice, in a certain place, and at a certain time: but the word in its present acceptation is used for the court, place, or time when and where the writs and processes, whether civil or criminal, are decided by judges and jury.

ASSOCIATION *of ideas* is where two or more ideas constantly and immediately follow one another, so that the one shall almost infallibly produce the other, whether there is any natural relation between them or not.

ASSONIA, in botany, a genus of plants of the class and order monadelphia dodecandria. The essential character is, calyx double, outer one three-leaved, inner one-leafed; corolla five-petalled; filament connected in form of a pitcher, with petal-shaped straps between; style one or five; capsule five-celled; seeds not winged. There are eleven species, the principal of which is a tree growing in the Isle of Bourbon.

ASSUMPSIT, a voluntary or verbal promise, whereby a person assumes, or takes upon him, to perform or pay any thing to another.

ASSURANCE, or INSURANCE, in commerce, is a contract or engagement, by which one person becomes bound, for a specified sum, to insure, for a limited time, the property of another against certain risks to which it is exposed. The party who engages to indemnify for the loss that may be sustained, is called the insurer, or underwriter; the compensation paid for the risk, the *premium;* and the document containing the obligation, the *policy*.

Assurances are distinguished by the offices in the following manner. 1. Common assurances, which include all manner of buildings, having the walls of brick, or stone, and covered with tile, slate, or metal, wherein no hazardous trades are carried on, nor any hazardous goods deposited. 2. Hazardous assurances, or assurances on timber or plaster buildings, in which hazardous trades are carried on, and hazardous goods deposited. 3. Doubly hazardous assurances, or assurances on any of the hazardous trades carried on, or on any hazardous goods deposited in buildings of timber or plaster, &c.

Dr. A. Smith, in 1775, supposed, that taking the whole kingdom at an average, 19 houses in 20, or perhaps 99 in 100, were not insured from fire. But the case is now very different, as there is scarcely any considerable town in England which has not in it either an office of its own, or agents from the London offices for effecting assurances.

ASTER, in botany, STAR-WORT, a genus of the polygamia superflua order and syngenesia class of plants, and in the natural method ranking under the 49th order, compositi radiati. The receptacle is naked, the pappus simple, the rays of the corolla more than ten, and the calyx is imbricated. There are 60 species. All of them may be raised from seed; but the greatest part of them being perennial plants, they are generally propagated by parting their roots early in the spring. They grow best in the shade.

ASTERIA, in natural history, a beautiful pellucid gem, of variable colours as viewed in different lights: called also *oculus cati, or cat's eye.*

ASTERIA is also the name of an extraneous fossil, called, in English, the star-stone.

ASTERIAS, in natural history, *star-fish,* a genus of worms, of the order Mollusca. Body depressed, covered with a coriaceous crust, muricate, with tentacula, and grooved beneath; mouth central, five-rayed. There are more than 40 species, all inhabitants of the sea, and are marked with a rough, white, stony spot above: they easily renew parts which have been lost by violence, and fix themselves to the bottom by swimming on the back and bending the rays.

ASTEROIDS, in astronomy, a name given by Dr. Herschell to the new planets, Ceres, Juno, Pallas, and Vesta, lately discovered; and which he defines as celestial bodies, which move in orbits either of little or of considerable eccentricity round the sun, the plane of which may be inclined to the ecliptic in any angle whatsoever.

ASTHMA, in medicine, a painful, difficult, and laborious respiration, occasioned by intolerable straitness of the lungs, which, as it disturbs the free circulation of the blood through the lungs, endangers a suffocation.

This disorder is attended with violent motions of the diaphragm, abdominal and intercostal muscles, to the very scapula and pinnæ of the nostrils. It is usually divided into pneumonic and convulsive: and is also either continual, or intermitting and periodical, and returns commonly when a sober regimen is not observed.

ASTRAGAL, in architecture, a little round moulding, in form of a ring serving as an ornament at the tops and bottoms of columns. See ARCHITECTURE.

ASTRAGAL, in gunnery a round moulding encompassing a cannon, about half a foot from its mouth.

ASTRAGALUS, *milk-vetch*, in botany, a genus of the diadelphia decandria class of plants, with a papilionaceous flower, and bilocular-podded fruit, containing kidney-like seeds. There are upwards of 60 species; all of which may be raised from seeds.

ASTRANTIA, *masterwort*, a genus of the digynia order and pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The involucrum is lanceolated, open, equal, and coloured. The species are five, but possess no remarkable properties.

ASTROLABE, an instrument for taking the altitude of the sun or stars at sea, being a large brass ring, the limb of which, or a convenient part thereof, is divided into degrees and minutes, with a moveable index, which turns upon the centre, and turns two sights: at the zenith is a ring to hang it by in time of observation, when you need only turn the index to the sun, that the rays may pass freely through both sights; and the edge of the index cuts the altitude upon the divided limb.

ASTROLOGY, a conjectural and truly absurd science, which teaches to judge of the effects and influences of the stars, and to foretel future events by the situation and different aspects of the heavenly bodies.

ASTRONIUM, in botany, a genus of plants of the pentandria order and diœcia class

The male calyx is five-leaved, and corolla quinquepetalous. The female calyx and corolla are the same as the male; the styli are three, and seed one. There is only one species, which is a native of Jamaica.

ASTRONOMY, the most sublime, useful, and interesting of all the sciences cultivated by mankind, treats of the heavenly bodies and their various phenomena. By some the term is extended to the theory of the universe, with the primary laws of nature; but, properly speaking, astronomy is a mixed mathematical science, by which we become acquainted with the magnitudes, motions, periods, distances, eclipses, &c. of the celestial luminaries.

Astronomy is unquestionably a science of very great antiquity, and, indeed, must have been coeval with the human race, since we cannot suppose that the exhibition of the Divine glory, which is afforded by the heavenly bodies, could fail to attract the attention, and excite the curiosity of those who first beheld it. It is, however, quite uncertain, in what age or country the united observations of many were so far methodized as to raise astronomy to the dignity of a science, and conjectures on the subject would be vain.

Those who have written on the history of astronomy seem agreed that the foundation for a regular system of this science was laid by Hipparchus, who flourished at Alexandria about 162 years before Christ. This philosopher, who was a native of Bithynia, determined the length of the tropical year with unprecedented accuracy; his result not varying more than 4½ minutes from the truth.

In the sixteenth century astronomy began to assume a more rational appearance from the introduction of the system of Copernicus, published at Nuremberg, and afterwards perfected by Kepler and Galileo.

The ancient philosophers, Pythagoras excepted, entertained the idea of the immobility of the earth. This system, called the Ptolemaic system, from Ptolemy, an Egyptian astronomer, places the earth in the centre, and the other planets round about her in the following order: viz. the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn, beyond which were situated the fixed stars.

This system, which is replete with difficulties, gave way to that which is commonly known by the name of the Copernican system, from the inventor Nicholas Copernicus. This philosopher, with the view of obviating the difficulties of preceding systems, admitted the motion of the earth on her own axis, and also her motion in the ecliptic round the sun. This system met with much opposition; and for maintaining it, Galileo was thrown into the prison of the Inquisition, and purchased his liberty by a recantation of the alleged heresy.

But however accordant with the principles of reason and common sense the system of Copernicus was, it met with a powerful opposition for a time from Tycho Brahe.

From observing that a stone thrown from the top of a lofty tower fell at its base, Tycho supposed that the earth must be without motion; not being aware that the same thing would happen on board a ship sailing at a swift rate, where, if a stone be dropped from the mast head, it will fall at the foot of the mast, provided the motion of the vessel be neither accelerated nor retarded during the time of falling.

This new system, which exceeded the Ptolemaic in confusion and difficulty, died with its projector, and the Copernican system is now universally received.

OF THE APPARENT MOTION OF THE HEAVENLY BODIES.

The circle which terminates our view on all sides, by the apparent meeting of the heavens and earth is called the horizon; which is a great circle of the sphere dividing the concave heavens into two parts, the visible above and the invisible below. The general appearance, therefore, of the starry heavens, is that of a vast concave sphere turning round two fixed points, opposite each other; the one in the northern hemisphere, called the zenith, and that in the southern, called nadir. The fixed points, round which this sphere is supposed to turn, are the poles, and a line drawn from one to another is called the axis of this sphere.

We shall endeavour to illustrate this by means of a diagram. Let HO plate VI. fig. 1, represent the circle of the horizon seen edgeways, when it appears as a straight line; let HPFORQ be the complete sphere of the heavens, of which let HPEO be the visible hemisphere; and HQRO the invisible; then will P be the pole of the former, and R the pole of the latter, and the line PR the axis of the sphere. Draw the line QE through the centre of the sphere C, and it will represent the edge of a great circle equally distant from both poles, and at right angles to the axis; this is called the *equator*, because it divides the heavens into two equal parts. If HO be the horizon, the highest point, or that over our heads, as M, is called the zenith; and the opposite one N, the nadir.

The sun rises in the east, ascends to the highest point in the arch, which he describes, and descends in the west. The highest point to which he ascends is called the mid-day point; through which, and the zenith, if a great circle is drawn, it is called the meridian of the place; and all the stars cross this circle or meridian twice in twenty-four hours, but those which go below the horizon are seen only to cross it once. The three great circles in the heavens are, the horizon, the equator, and the meridian. The first determines the rising and setting of the heavenly bodies; and also their altitude, for which last purpose we must suppose another great circle to pass through the star and the zenith, called a vertical circle, upon which we reckon the number of degrees the star is from the horizon. The quadrant is an instrument used to ascertain this altitude. The three great circles above mentioned form the basis of all observations on the heavenly bodies; and, therefore, it is necessary to determine their relative situations. Had the polar star been exactly at the pole nothing more need be done than to obtain the altitude of this star for that of the pole; but as it is two degrees from the pole, that number must be added to this altitude to find that of the pole.

The elevation of the pole being found it is easy to find that of the equator: thus HMO, or the visible part of the heavens contains 180

deg.; but it is 90 deg. from the pole P to E the equator: now if PE be taken from the semicircle HMO, there remain 90 deg. for the other two arcs; or, the elevation of the pole and equator are together equal to 90 deg.; so that the one being known and subtracted from 90 deg. it will give the other, consequently, the elevation of the pole, at any place, is the complement of the elevation of the equator, and the elevation of the equator is equal to the distance from the pole to the zenith.

The sun does not always rise at the same point; for in the beginning of March he appears to rise more to the north every day, to continue longer above the horizon, and to be higher at mid-day. Thus he continues till towards the end of June, when he retrogrades in the same order till near the end of December, when he begins to move forward as before. This change in the sun's place occasions the difference in the length of the days and nights, and the vicissitudes of the seasons.

The ecliptic is that path or great circle which the sun is supposed to complete in a year. It differs in situation from the equator; for the sun rises above the equator in summer, and not so high in winter. The points of the ecliptic where the sun is when at the greatest distance from the equator are called solstitial points; and the distance between the equator and ecliptic, at those points, is named the obliquity of the ecliptic, which is nearly 23 deg. 30 min.

The equinoctial colure is the great circle which passes at right angles to the equator, through the two points of it intersected by the ecliptic, and called the equinoctial points. The solstitial colure is the other great circle at right angles to the equator, and passes through the poles of the ecliptic.

Lesser circles of the sphere, touching the solstitial points, and at right angles to the axis, as AC, BD are called tropics: that on the north side of the equator is denominated the tropic of Cancer; and that on the south, the tropic of Capricorn. The two polar circles FG, IK are 23 deg. 30 min. distant from the poles.

The zodiac is a broad portion of the heavens, extending about eight degrees on each side of the ecliptic; it is divided into twelve parts, called signs; and each sign into thirty parts or degrees. Circles of celestial longitude are great circles of the sphere, standing at right angles to the plane of the ecliptic, dividing the same into equal parts. Upon the ecliptic is reckoned the longitude of any fixed star, from the point where the ecliptic and equator intersect each other in the vernal equinox, called the first point of Aries, and the arch of any of these circles intercepted between a star and the ecliptic, is the latitude of that star. The equator is divided into degrees, called degrees of right ascension, and from the equator to the poles the degrees of declination are counted on the meridian of the place.

OF THE SOLAR SYSTEM.

If we examine the heavens in a clear night we shall find that the greater of the stars keep the same place with respect to each other, that is, if we observe two stars having a certain apparent distance from one another one night, they will be found to maintain the same distance every succeeding night; these are therefore denominated fixed stars.

But there are others which change their places with regard to the fixed stars, and also to one another. These were formerly five; but Dr. Herschell has discovered a sixth, which he has named Georgium Sidus, though foreign astronomers give it the name of the person who discovered it. Four others have been since discovered by Piazzi, Olbers, and Harding are admitted into the system under the names of Ceres, Pallas, Juno, and Vesta. All these are denominated planets from the word *plano* to err or wander. Besides these there are secondary planets, called satellites or moons, which revolve round certain of the primary ones. Of these our earth has one, Jupiter four, Saturn seven, and the Georgium Sidus six. All the planets move round the sun, from east to west, and in the same direction do the moons revolve round their primaries; excepting those of the Herschell, which seem to move in an opposite direction. The paths in which they move round the sun, are called their orbits, which are ellipses approaching very near to circles. Their revolutions are performed in different periods of time; each of which is the year of the respective planet. See the Table at the end of this article.

The planets are opaque bodies, and shine by reflecting the light which they receive from the sun. Venus and Mercury being nearer to the sun than to our earth are called inferior planets, and the rest, which are without the earth's orbit, are denominated superior planets. We have already said that the planets move round the sun in elliptical orbits; that in which the sun is situated is called the lower focus. If we suppose the plane of the earth's orbit which passes through the centre of the sun, to be extended in every direction as far as the fixed stars, it will describe a great circle, or the ecliptic, with which the situations of the orbits of the other planets are compared.

The planes of the orbits of all the other planets must pass through the centre of the sun; but if extended as far as the fixed stars they form different circles from each other and from the ecliptic; one part of each orbit being on the north, and the other on the south side of the ecliptic. Therefore the orbit of each planet cuts the ecliptic in two opposite points called *the nodes of the planet*. That where the planet passes from the south to the north of the ecliptic is called the ascending node, and the other *the descending node*. The angle which the plane of a planet's orbit makes with the plane of the ecliptic is called the inclination of the planet's orbit.

The two points in a planet's orbit farthest from, and nearest to, the body round which it moves, are called the apsides, the former of which is usually named the aphelion, and the lower, the perihelion; the diamater joining these points is called the line of apsides. When the sun and moon are nearest the earth, they are said to be in perigee, and when farthest from it to be in apogee.

When a planet is between the sun and the earth, or the sun is between it and the earth, then the planet is said to be in conjunction with the sun; and when the earth is between a planet and the sun, that planet is said to be in opposition. When a planet comes between

the earth and the sun, it appears to pass over the disc, or surface of the latter, and this is called the transit of the planet.

When a planet moves from west to east, it is said to have direct motion, or to be in consequentia; and when from east to west, to have retrograde motion, or in antecedentia. The heliocentric place of a planet, is the place which it appears to be in if viewed from the sun; and the place it occupies when viewed from the earth is termed its geocentric place.

The planets do not move with equal velocity in all parts of their orbits, but move faster when nearest to the sun, and slower in the remotest parts; and if a straight line is drawn from the planet to the sun, and this line is supposed to be carried along by the periodical motion of the planet, then the areas described by this line, and the path of the planet, are proportioned to the times of the planet's motion.

The planets perform their periodical revolutions in different times, but the cubes of their mean distances are as the squares of their periodical times.

The sun forms the centre of attraction round which all the planets move. These have also the property of attracting each other, which occasions some irregularity in their motions. This mutual attraction between the planets and the sun keeps them from flying off from their orbits by the centrifugal force, which is generated by their revolving in a curve; and this force again keeps them from falling into the sun, which would be the case, if it were not for the motion impressed upon them. Thus these two powers balance each other, and preserve the order of the system.

This doctrine, which is founded on the demonstrations of Sir Isaac Newton, may be thus illustrated:

If a planet at B (fig. 2. plate VI.) gravitates, or is attracted towards the sun, S, so as to fall from B to *y*, in the time that the projectile force would have carried it from B to X, it will describe the curve BY by the combined action of these two forces, in the same time that the projectile force, singly, would have carried it from B to X, or the gravitating power, singly, have caused it to descend from B to *y*; and these two forces being duly proportioned, the planet obeying them both will move in the circle BYTV. But if, whilst the projectile force would carry the planet from B to *b*, the sun's attraction should bring it down from B to I, the gravitating power would then be too strong for the projectile force, and would cause the planet to describe the curve BC. When the planet comes to C, the gravitating power (which always increases as the square of the distance from the sun, S, diminishes) will be yet stronger for the projectile force, and by conspiring, in some degree, therewith, will accelerate the planet's motion all the way from C to K, causing it to describe the arcs BC, CD, DE, EF, &c. all in equal times. Having its motion thus accelerated, it thereby acquires so much centrifugal force, or tendency to fly off at K, in the line K *k*, as overcomes the sun's attraction; and the centrifugal force being too great to allow the planet to be brought nearer to the sun, or even to move round him in the circle *k l m n*, &c. it goes off, and ascends in the curve KLMN, &c. its motion decreasing as gradually from K to B as it increased from B to K, because the sun's attraction now acts against the planet's projectile motion just as much as it acted with it before. When the planet has got round to B, its projectile force is as much diminished from its mean state as it was augmented at K; and so the sun's attraction being more than sufficient to keep the planet from going off at B, it describes the same orbit over again by virtue of the same forces or powers. A double projectile force will always balance a quadruple power of gravity. Let the planet at B have twice as great an impulse from thence towards X as it had before; that is, the same length of time that it was projected from B to *b*, as in the last example; let it now be projected from B to *c*, and it will require 4 times as much gravity to retain it in its orbit; that is, it must fall as far from B to 4 in the time that the projectile force would carry it from B to C, otherwise it would not describe the curve BD, as is evident from the figure. But in as much time as the planet moves from B to C, in the higher part of its orbit, it moves from I to K, or from K to L, in the lower part thereof; because from the joint action of these two forces, it must always describe equal areas in equal times throughout its annual course. These areas are represented by the triangles BSC, CSD, DSE, ESF, &c. whose contents are equal to one another from the properties of the ellipses.

OF THE SUN.

From the motion of the spots which appear on the face of the sun, it has been found that this great luminary revolves on its axis in twenty-five days. This axis is inclined to the ecliptic, in an angle of about 82° 30′.

The following are Sir Isaac Newton's observations on the sun. 1. That its heat is seven times greater in Mercury, than with us, and that water there would be all carried off in steam. 2. That the quantity of matter in the sun is to that of Jupiter, as 1100 to 1, and that the distance of Jupiter from the sun is in the same ratio to the sun's diameter; consequently the centre of gravity of the sun and Jupiter, is nearly in the superficies of the former. 3. That the quantity of matter in the sun, is to that of Saturn, as 2360 to 1, and the distance of Saturn from the sun is in a ratio little less than that of the sun's semi-diameter, whence the common centre of gravity of Saturn, and the sun is a little within the latter. 4. Therefore the common centre of gravity of all the planets cannot be more than the length of the solar diameter from the centre of the sun. 5. The sun's diameter is equal to 100 diameters of the earth, and the whole body exceeds that of the earth a million of times. 6. If 360 degrees are divided by the quantity of the solar year, it gives 59′ 1″, and the horary motion is 2′ 27′.

OF THE INFERIOR PLANETS.

Mercury being nearest the sun, is seldom visible, and never appears more than a few degrees from the sun's disc. The period of its revolution on its axis is unknown. It is sometimes seen passing over the solar disc, and this is called its transit. Venus is the brightest of the planets, and is termed the morning or

evening star, as it precedes or follows the apparent course of the sun. The time of its rotation on its axis is not known. Venus appears with phases like the moon, and passes sometimes over the sun's disc.

The *elongation* of a planet is its apparent distance from the sun.

An inferior planet is at its greatest elongation when a line drawn from the earth, through the planet, is a tangent to the planet's orbit.

OF THE EARTH.

That our planet is a globular body, is easily proved. Mariners, when they leave land, first begin to lose sight of the lower parts, and so on gradually of the higher: and persons on shore, first see the tops of the masts, before the ships themselves appear. Now, if the earth were a perfect plane, all parts would be seen at once. The earth is not, however, a perfect sphere, but a spheroid, having its equatorial diameter longer than the polar, or the axis, The diameter, at the equator, is 7977 miles. and that at the poles 7940 miles. The earth has two motions; a diurnal, on its own axis in twenty-four hours, and an annual motion round the sun in 365 days 6 hours 56m. 4s. The first motion occasions light and darkness, day and night.

The natural days are not equal; for a natural day is the time wherein the earth performs one revolution round its axis, and such a portion of the second revolution as is equal to the space which the sun has apparently gone that day; but these spaces are unequal, therefore the additional portion of the second revolution will be at times greater or less, consequently the natural days must be unequal. Hence arises the difference between a sun-dial and a time-piece, the former measuring the length of a natural day, and the latter dividing time into equal portions of twelve hours each; the clock will be before the dial when the natural day is more than twenty-four hours, and after it when less.

The *equation* of time is the difference between the mean length of the natural day, and that of a day measured by the sun's apparent motion, or between *mean* and *apparent* time. The hour by apparent time being known, to find what is the true time, add the equation to apparent time, if the day, by the clock, is shorter than by the dial; and subtract it when longer.

The causes of the difference between mean and apparent time, are, 1. The obliquity of the ecliptic with regard to the equator. 2. The unequal motion of the earth in an elliptical orbit.

The heavenly bodies appear higher than they really are, owing to the refraction of the rays of light by our atmosphere; so that to bring the apparent to the true altitudes, the quantity of refraction must be subtracted according to a table which may be found in all books of elemental astronomy.

The twilight is also owing to this refraction of the rays, which, being bent by the atmosphere, visit the earth before the sun actually rises, and keep him in view after he is set.

OF THE SEASONS.

These are occasioned by the annual motion of the earth. The better to understand this, it must be considered that the axis of the earth is inclined to the plane of its orbit, about 23d 30m. and it always keeps parallel to itself, or is directed constantly to the same point of the heavens.

Let fig 4, Plate VI. represent the earth in different parts of its elliptic orbit. In the spring, the circle which separates the light from the dark side of the globe called the terminator, passes through the poles *n*, *s*, as appears in the position A. The earth then, in its diurnal rotation about its axis, has every part of its surface as long in light as in shade; therefore the days are equal to the nights all over the world; the sun being at that time vertical to the equatorial parts of the earth. As the earth proceeds in its orbit, and comes into the position B, the sun becomes vertical to those parts of the earth under the tropic, and the inhabitants of the northern hemisphere will enjoy summer on account of the solar rays falling more perpendicularly upon them; they will also have their days longer than their nights, in proportion as they are more distant from the equator; and those within the polar circle, as will be perceived by the figure, will have constant day-light. At the same time the inhabitants of the southern hemisphere have winter, their days being shorter than their nights, in proportion as they are farther from the equator; and the inhabitants of the polar regions will have constant night. The earth then continues its course to the position C, when the terminator again passes through the poles, and the days and nights are equal. After this the earth advances to the position D, at which time the inhabitants of the northern hemisphere have winter, and their days are shorter than their nights. The positions B and D are the solstitial points, and A and C the equinoctial points; they are not equidistant from each other, because the sun is not in the centre, but in the focus of the ellipsis. In summer, when the earth is at B, the sun is farther from it than in winter, when the earth is at D; and, in fact, the diameter of the sun appears longer in the winter than in summer. The difference of heat is not owing to the sun's being nearer to us, or more remote, but to the degree of obliquity with which its rays strike any part of the earth

OF THE MOON.

The moon is a spherical body, and revolves round the earth in an elliptical orbit, and is carried with it round the sun. The moon always has the same side towards us, and its periodical time is equal to that of its revolution in its orbit round the earth. Though the year to the earth and moon is of the same length, the number of their days is different: the former having 365 natural days, and the latter only about 12, every day and night in the moon being equal to 29 days 30 hours on the earth. The face of the moon, as seen through a telescope, appears diversified with mountains and valleys. The height of the lunar mountains has been accurately ascertained by Dr. Herschel, who concludes, that with few exceptions they do not exceed half a mile. The same astronomer also discovered several volcanoes in the moon.

The phases of the moon, as they appear at eight different points of her orbit are represented in plate VII, where S represents the sun.

T the earth, and ABCD, &c. the moon's orbit. When the moon is at A, in conjunction with the sun S, her dark side being entirely towards the earth, she will be invisible, as at *a*, and is then called the new moon. When she comes to her first octant at B, a quarter of her enlightened hemisphere will be turned towards the earth, and she will then appear horned, as at *b*. When she has run through the quarter of her orbit, and arrived at C, she shews us the half of her enlightened hemisphere as at *c*, when it is said she is one half full. At D she is in her second octant, and, by shewing us more of her enlightened hemisphere than at C, she appears gibbous as at *d*. At her opposition at E, her whole enlightened side is turned towards the earth, when she appears round, as at *e*, and she [illegible] said to be full; having increased all the way round from A to E. On the other side she decreases again all the way from E to A; thus, in her third octant at F, part of her dark side being turned towards the earth, she again appears gibbous, as at *f*. At G she appears still farther decreased, shewing again exactly one half of her illuminated side, as at *g*. But when she comes to her fourth octant at H, she presents only a quarter of her enlightened hemisphere, and again appears horned, as at *h*. And at A, having now completed her course, she again disappears, and becomes a new moon again, as at first.

OF THE SUPERIOR PLANETS.

Mars is of a reddish colour, and from some spots on its surface, it appears that the inclination of the axis of this planet to the ecliptic is 59d. 42m. the node of the axis is in 17d. 47m. of Pisces, the obliquity of the ecliptic thereon, 28d. 42m.

The figure of Mars is that of an oblique spheroid, the equatorial diameter of which is to the polar, as 16 to 15.

Ceres Ferdinandea, is the name of a small planet situated next beyond Mars, and was discovered on the first day of the present century, by Piazzi, an Italian astronomer.

Pallas is another small planet, discovered by Dr. Olbers, of Bremen, in 1802. Juno is another small planet, discovered by M. Harding, in 1804, and Vesta, another, was first seen by Dr. Olbers, March 29th, 1807.

These four planets Dr. Herschel calls asteroids. Jupiter is the brightest of the planets, except Venus. Several belts are observed across its surface, and parallel to its equator. These are supposed to be large ranges of clouds in the atmosphere of the planet, as they are sometimes of different breadths. Large spots have also been seen in these belts. Jupiter has four moons of different magnitudes, which are occasionally eclipsed by the shadow of the planet falling on them. These are of considerable use in astronomy and navigation, for the purpose of determining the longitudes of places.

Saturn is seldom seen by the naked eye. Viewed through a telescope, it presents a remarkable appearance, being surrounded by a luminous ring. This ring, which casts a strong shadow upon the planet, appears to be divided into two by a line in the middle of its breadth. Besides, the ring Saturn has seven moons of different sizes; and on its body it has belts like those of Jupiter.

The Georgium Sidus, or Herschel planet, with its six satellites, was the discovery of Dr. Herschel, in 1781. It cannot be seen but by a telescope.

It is evident, from the principles of optics, that the determination of the real diameters of the celestial bodies, depends on the knowledge of their apparent diameters, and their actual distances from the earth.

The sun's vertical, or perpendicular diameter, may be had by two observers taking, at the same time, one the height of the upper edge of the disc, the other the lower. This will be best done when the sun is at the meridian. The height of each edge must be corrected by allowing for parallax and refraction; and the apparent diameter will be equal to the difference of the corrected altitudes of the upper and lower edge. Another method is, to observe by a good clock, the time in which the sun's disc passes over the plane of the meridian, or some other hour circle. At, or near one of the equinoxes, when the sun's apparent diurnal motion is in the equator, or a parallel near it, say, at the time between the sun's leaving the meridian and return to it : 360d. : : the time in which he passes over the meridian : his apparent semi-diameter. At any other time of the year, when the sun is in a parallel at a greater distance from the equator, say, as radius : the sine of the sun's declination : : the time in which the sun passes the meridian, converted into motion at the rate of four minutes in time to 1d. : the arc of the great circle which measures the sun's apparent horizontal diameter.

OF THE SATELLITES.

As the satellites uniformly describe orbits nearly with their respective primaries, at the centre or focus, they are most probably moved by a similar force to that which moves the planets round the sun, consequently they must describe the areas of their orbits proportional to the times: and their mean distances from the centres of the primaries must be the cube-roots of the squares of the times of their revolutions.

The time of a synodic revolution of a satellite may be thus found: observe when the primary planet is in opposition to the passage of the satellite over its body, and mark the time when it is half-way between the two opposite edges of the planet's disc, for then it will be nearly in conjunction with the centre of the planet, and also in conjunction with the sun. After some time, observe when the primary is in opposition, and the satellite in conjunction with its centre, and divide the intervening period between the two observations, by the number of conjunctions of the sun, in that space, which will give the time of a synodic revolution. Another method is by means of the eclipses of the satellites; observe when the satellite enters the shadow of its primary, called its immersion, or when it comes out of the shadow, called its emersion; and after some time repeat the same observation when an eclipse again occurs, and from the interval of these times, and the number of eclipses in that interval, the mean time of a synodic revolution will be had by division.

The distance of a satellite from its primary, may be found by means of its greatest elonga-

tion, as seen from the earth. Another method is, by measuring with a micrometer at the time of the satellite's elongation, its distance from the centre of the planet, also the semi-diameter of the planet, the distance being in the same terms as the semi-diameter. Or when the periodic times of all the satellites are known, and the mean distance of one of them; the mean distances of the others may be found from the proportion between the squares of the periodic times and the cubes of the distances

OF COMETS.

These are opaque bodies, with long tails, or trains, on the side remote from the sun, round which they revolve in eccentric ellipses; Sir Isaac Newton computed the heat of the comet which appeared in 1680 to be, when nearest to the sun, 2000 times hotter than red hot iron. In their motions round the sun, the comets are subject to the same irregularities as the planets, only their variations are more considerable. When they are near the sun, their motion is very rapid, and in the remoter parts of their orbits extremely slow. Dr. Halley has calculated tables for determining the orbits of the comets, which, in general, have been found very exact. The number of comets belonging to our system is unknown; but, from the accounts of the ancients, and the observations of the moderns, it appears that about 450 had been seen previous to 1771, and since that time, several others have occasionally been discovered.

OF THE FIXED STARS.

Th[illegible] called, on account of their not changing their places as the planets do. They appear of various magnitudes; but, for convenience, astronomers class them into six or seven divisions. To the naked eye they seem to be innumerable, but this is a deception occasioned, probably, by the refraction of our atmosphere.

The ancients divided the stars into several constellations, or systems; to distinguish which, they gave them names according to their fancies To these have been added several others by modern observers.

Those stars which are not included in any constellation, are denominated unformed. Besides the names of the constellations, the ancient Greeks gave particular appellations to some single stars, or small groupes of them; thus, those in the neck of the Bull were called Pleiades; five in the Bull's face, Hyades; a bright star in the breast of Leo, the Lion's Heart; and one between the knees of Bootes. Arcturus.

Greek letters have been added by Bayera to stars in the several constellations of his catalogue, (α being affixed to the largest star) by means of which, any star may be easily found.

Twelve of the constellations lie upon the ecliptic, including a space about 16 degrees in breadth, called the zodiac, within which all the planets move. The constellations as far as the triangle, with Coma Berenices, are northern, those after Pisces, southern. The distances of the fixed stars from us cannot be ascertained, therefore they must shine by their own light as our sun does, whence it is inferred, that they are suns to systems similar to ours. Some of the larger stars have not the same situations observed by ancient astronomers; and new stars have appeared, while others, formerly described, are no longer seen. Some stars have a periodical increase and decrease: and many of the fixed stars, upon examination by the telescope, are found to consist of two.

The *via lactea* or milky way, is a broad belt or zone, of a whitish appearance, which consists of an infinite number of small stars not to be discerned but by a very powerful telescope. Dr. Herschell is of opinion, that the universe is full of these nebulæ or systems of stars, and that the milky way is the nebula in which our system is situated.

OF ECLIPSES.

When any of the heavenly bodies is obscured, or darkened by the shadow of another falling upon it, or by the interposition of any body, it said to be eclipsed. Eclipses were formerly viewed as ominous, but the improvements of science have clearly proved that they have no connection with future events; but that they depend entirely upon regular and invariable causes, and may be calculated and foretold with the greatest certainty. As the earth is an opaque body, enlightened only by the sun, it will cast a shadow towards that side which is farthest from the sun. As the sun is much larger than the earth, the shadow of the latter must be conical, or end in a point. See plate VI. fig. 5.

On the sides of this conical shadow, there is a diverging shadow, the density of which decreases in proportion as it recedes from the sides of the former conical shadow: this is called the penumbra. As the moon revolves round the earth sufficiently near to pass through the shadow of the earth, an eclipse must always take place when these three are all in one straight line. An eclipse of the moon can never happen but at the time of full moon; but on account of the inclination of the moon's orbit to that of the earth, an eclipse cannot take place every full moon. When the moon passes entirely through the earth's shadow, the eclipse is total; but when only part of it passes through the shadow, the eclipse is partial. The quantity of the moon's disc which is eclipsed, (and the same thing is to be understood of that of the sun in a solar eclipse,) is expressed by twelve parts, called digits, that is, the disc is supposed to be divided by twelve parallel lines; then if half the disc is eclipsed, the quantity of the eclipse is said to be six digits. When the diameter of the shadow, through which the moon must pass, is greater than the diameter of the moon, the quantity of the eclipse is said to be more than twelve digits; thus, the diameter of the moon is to that of the shadow as four to five, then the eclipse is said to be fifteen digits. The duration of a lunar eclipse is various, it sometimes lasts two or three hours. The eclipses of the sun are owing to a different cause than those of the moon. They are occasioned by the moon's coming directly between us and the sun, and therefore obstructing our view of it. When the moon happens to be in conjunction with the sun, or between the sun and the earth, *viz.* at the time of the new moons, the shadow of the moon falls upon the surface of the earth; hence, properly speaking, such

eclipses should be called *eclipses of the earth.* But the whole disc of the earth cannot be involved in the shadow of the moon, because the moon is much smaller than the earth, and the shadow of the moon is conical. Thus, in plate VI. fig. 6, the rays of the sun, S, being intercepted by the moon, L, form the conical shadow CDG, which, falling upon the surface of the earth, entirely deprives that portion of it, upon which it falls, of the sun's light, and of course the inhabitants of that part of the earth will have a total eclipse of the sun. Beyond the dense conical shadow CDG there is a diverging half shadow, or penumbra CDEF, which is occasioned by the moon's intercepting only a part of the sun's rays from those places which fall within this penumbral cone, and are out of the dense shadow. Thus from the part of the earth Z, the portion YYB of the sun only can be seen; consequently the inhabitants of that part will have a partial eclipse.

As the moon is not always at the same distance from the earth, it sometimes happens that the conical dense shadow does not reach the earth, as in fig. 7, and only the penumbral shadow falls upon it, the eclipse consequently is partial to every part of the earth. Those who are at the centre of the penumbra will lose sight of the centre of the sun, by the interposition of the moon's body, which subtending a smaller angle than the sun, will not entirely [illegible] 'll be a ring of light all around. The eclipse is then said to be annular.

OF THE TIDES.

The ocean covers more than half the globe; and this large body of water is in continual motion, ebbing and flowing alternately; that is, if the tide is now at high water mark, it will presently subside and flow back for about six hours, when it will be at low water mark: the time of high water, however, is not always the same, but is about three quarters of an hour later every day, for near thirty days, when it begins as before.

For example: suppose at a certain place, it is high water at three o'clock in the afternoon on the day of new moon; the next day it will be high water at three quarters of an hour after three, the day following at half-past four, and so on till the next new moon, when it will be again high water at three. This answers to the motion of the moon; for she rises every day about three quarters of an hour later than the preceding one; and thus completes her revolution round the earth in about thirty days.

According to the Newtonian principle of attraction, these phænomena are thus explained. The waters at Z on the side of the earth, *next the moon M, (figure 3.) are more attracted than the central parts O by the moon,* and these again more than the waters on the opposite side at N; therefore the distance between the earth's centre and the waters on its surface under and opposite the moon will be increased. To explain this more particularly, though the earth's diameter bears a considerable proportion to its distance from the moon, yet this diameter is nothing when compared to the earth's distance from the sun, consequently the difference of the sun's attraction on the sides of the earth opposite to him, will be far less than the difference of the moon's attraction on the sides opposite to her; therefore the moon must raise the tides higher than they could be by the sun. Sir Isaac Newton has determined that the influence of the sun in this case is three times less than that of the moon. The tides, then, are properly the joint production of the sun and moon; or, in fact, there are two tides, a solar and a lunar, whose effects are joint or opposite according to the situation of the bodies by which they are effected. When the sun and moon act together, as at new and full moon, the flux and reflux become considerable; and are called spring tides. But when one tends to elevate the waters, and the other to depress them, as at the moon's first and third quarters, then the flux and reflux will be diminished; these are called neap tides.

The sun being farther from our hemisphere in March and September, than in February and October, is the cause why the greatest tides happen a little before the vernal, and a little after the autumnal equinox.

When the moon is in the equator, the tides are equally high in both parts of the lunar day, which is 24 hours 50 minutes; but as she declines towards either pole the tides are alternately higher or lower in northern or southern latitudes. The tides are so retarded in their passage through channels, and so affected by capes, and head-lands, as to happen variously at different places. The tide raised in the German Ocean, when the moon is three hours past the meridian, takes three hours to arrive at London Bridge. Lakes have no tides because every part is attracted alike. The Mediterranean and Baltic seas have but small elevations, on account of the narrowness of the inlets by which they communicate with the ocean.

For more ample information on the subject of astronomy, the reader is referred to the works of Ferguson, Gregory, Bonnycastle, Vince, Squire, and others.

The following Tabular view of the Solar System is taken from Ferguson's Astronomy by Dr. Brewster. Second edition.

TABULAR VIEW OF THE SOLAR SYSTEM.

Names of the Planets.	Mean diameters in English miles.	Mean diameters from the sun, in round numbers of miles.	The correct mean distances, that of the earth being 100000.	Mean apparent diameters as seen from the earth.	Mean diameters as seen from the sun.	Densities, that of water being 1.	Proportional quantities of matter.	Diurnal rotations round their own axis.	Inclination of axis to orbits.	Inclination of orbits to the ecliptic in 1780.

ASTROSCOPE, an instrument composed of two cones, having the constellations delineated on their surfaces, whereby the stars may be easily known.

ASYMMETRY, in a general sense, the want of proportion between the parts of any thing, being the contrary of symmetry.

In mathematics it is used for what is more commonly called incommensurability, or the relation of two quantities which have no common measure, as between one and the square root of two, or as $1 : \sqrt{2}$, or the side and diagonal of a square.

ASYMPTOTE, in geometry, a line which approaches nearer to another continually, and never meets it. Properly, the term is appropriated to right lines, which continue to approach nearer to curve.

ASYNDETON, in grammar, a figure which omits the conjunctions in a sentence, as in that verse of Virgil:

Ferte citi flammas, date vela, impellite remos.

ATCHIEVEMENT, vulgarly *hatchment*, in heraldry, the arms of a person or family with all the ornaments appended to it.

ATHAMANTA, in botany, a genus of the pentandria digynia class and order, in the natural method ranking under the forty-fifth order, umbellatæ. There are nine species, the principal of which is, the athamanta cretensis, or daucus creticus, which grows wild in the Levant. It rises about two feet in height, and the branches bear white flowers.

ATHANASIA, *goldilocks*, a genus of the polygamia æqualis order, and syngenesia class of plants, ranking in the natural method under the forty-ninth order, compositæ discoides. There are twenty species, but none remarkable.

ATHENÆA, a genus of plants, of the class and order octandria monogynia. There is only one species, which is an aromatic shrub that grows in Africa.

ATHENÆUM, in antiquity, a public place wherein the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances.

ATHERINA, in ichthyology, a genus of abdominal fishes, distinguished by having the upper jaw rather flat, six rays in the gill membrane, and a silvery stripe on each side of the body. There are five species of this genus: the most remarkable are:

1. Atherina hepsetus, with about 12 rays in the fin next the anus. It is found in the Mediterranean. It is also very common in the sea near Southampton, where it is called a smelt.

2. Atherina menidea, has 24 rays in the fin next the anus. This is a very pellucid fish, with many black points interspersed; it has many teeth in the lips, but none in the tongue or jaws. It is found in the fresh waters of Carolina.

ATHWART, in naval affairs, across the line of the ship's course, as "We discovered a fleet standing athwart us," i. e. steering across our way.

ATHWART *hawse*, the situation of a ship when she is driven, by an accident, across the stem of another, whether they bear against, or at a small distance from each other: the transverse position being principally understood.

ATLAS, in matters of literature, denotes a book of universal geography, containing maps of all the known parts of the world.

ATLAS, in commerce, a sort of silk or satin manufactured in the East Indies, in which gold and silk are so wrought together, as no workman in Europe can imitate. In China they weave long slips of gilt paper into their silks. The same slips of paper are twisted about silk threads so artificially, as to look finer than gold thread, though of no great value.

ATMOSPHERE. See PNEUMATICS.

ATOM, from the Greek ατομος, compounded of a privative, and τεμνω, I cut. The word is used to signify such a small particle of matter as cannot be physically divided. Such particles are said to be the first rudiments, or component parts of all bodies. See DIVISIBILITY.

ATOMICAL *philosophy*, the philosophy of Epicurus, which ascribes to atoms the properties of gravity and motion. On this ground that philosopher accounted for the origin and formation of things.

ATOMIC *theory*, a species of philosophy recently introduced into chemistry, the nature of which may be understood from the following brief outline.

The progress which chemists have made in the investigation of the component parts of bodies, has led to the adoption of this axiom, viz. that, "*Chemical union consists in the combination of the atoms of bodies with each other.*" Thus when two bodies unite chemically, so as to form a third body, the two substances united are dispersed every where through the new compound.

Water, for example, is composed of oxygen and hydrogen. Now, how minute soever the portion of water may be which we examine, it will be found to contain both oxygen and hydrogen. Saltpetre is a compound of nitric acid and potash. If we examine the salt whether we take an ounce or the hundredth part of a grain, we shall always find it to be a compound of nitric acid and potash. If any portion of it were to want one of these constituents, it would no longer be saltpetre; it would be potash, or nitric acid, according to the constituent which is not present. Limestone is a compound of carbonic acid and lime. Now we may reduce it to an impalpable powder; but if we take one of the grains of this powder, however small, and throw it into nitric acid, we shall perceive an effervescence, indicating the presence of carbonic acid, and it will dissolve, indicating that lime was also one of its constituents. Mechanical trituration, however carefully made, is quite incapable of separating from each other, substances which are chemically combined. Thus all chemical compounds contain the same constant proportion of constituents with the most rigid accuracy, no variation whatever taking place. See the article in the Supplement to the Encyclopædia Britannica.

ATRACTYLIS, a genus of the syngenesia polygamia class of plants, of which there are eight species. 1. Atractylis cancellata, or small cnicus is an annual plant, rising about eight or nine inches high, with a slender stem; at the top of the branches are two or three slender stalks, each terminated by a head of purple flowers. 2. Atractylis gummifera, or prickly gum bearing cnicus, called also carline thistle. It is a perennial plant; and has many white

and yellow florets in a prickly empalement. 3. Atractyilis humilis, or purple prickly cnicus, grows to the height of a foot, with purple flowers. They are all natives of the southern parts of Europe.

ATRETI, in medicine, a term applied to persons who have the anus, vagina, urethra, &c. imperforate, whether naturally or occasioned by disease.

ATRIPLEX, *orach*, in botany, a genus of the polygamia monœcia class of plants, without any flower petals; the cup of the female flower is composed of two leaves, inclosing a single and compressed seed; whereas that of the hermaphrodite flower is composed of five leaves, and incloses a single roundish, and depressed seed. There are fourteen species.

ATROPA, DEADLY NIGHT-SHADE; a genus of the monogynia order, and pentandria class of plants; and in the natural method ranking under the 25th order, luridæ. The corolla is campanulated; the stamina are distant; the berry is globular, and consists of two cells. There are eight species; of which the following are the most remarkable. 1. Atropa belladonna, which has a perennial root, with stalks and leaves of a purplish colour. The flowers are large, bell-shaped, and of a dusky colour. When the flower is past, the germen turns to a round berry, which is first green, but, when ripe, turns black, and contains a purple juice, and is full of small seeds. This species is remarkable for its poisonous qualities. A glass of warm vinegar will counteract its bad effects. 2. Atropa frutescens is a native of Spain, and rises to the height of 6 or 8 feet. The flowers are of a yellow colour, but are not succeeded by berries. 3. Atropa herbacea is a native of Campeachy, and grows to the height of two feet. The flowers are white. 4. Atropa mandragora, or the mandrake, which has been distinguished into the male and female. It is a native of the warm parts of Europe.

ATROPHY, in medicine, a disease wherein the body or some of its parts do not receive the necessary nutriment, but waste and decay incessantly.

ATTACHMENT, in law, is the taking or apprehending a person by a writ or precept: it is distinguished from arrest by its lying sometimes on goods only, and sometimes on goods and persons.

ATTAINDER, in law, is when a man has committed felony or treason, and sentence is passed upon him for the same. The children of a person attainted of treason, are, thereby, rendered incapable of being heirs to him, or to any other ancestor; and if he were noble before, his posterity are degraded and made base: nor can this corruption of blood be salved but by an act of parliament, unless the sentence be reversed by a writ of error.

Attainder, *bill of*, a bill brought into parliament for attainting, condemning, and executing a person for high-treason.

ATTIC, in architecture, a sort of building wherein the roof or covering is not to be seen; thus named, because the buildings at Athens were generally of this form.

ATTITUDE, in painting and sculpture, the gesture of a figure, or statue; or it is such a disposition of their parts, as serves to express the action and sentiments of the person represented.

ATTORNEY *General*, is a great officer under the king, created by letters patent, whose office it is to exhibit informations, and prosecute for the crown in criminal causes, and to file the bills in the exchequer, for any thing concerning the king in inheritance or profits. To him come warrants for making of grants, pardons, &c.

ATTORNIES *at law*, are such persons as take upon them the business of other men, by whom they are retained. No man can lawfully act in this capacity unless he has been bound, by contract in writing, for the space of five years to a regular attorney, and has, at the expiration of that period, been examined, sworn, admitted, and enrolled.

ATTRACTION, a general term used to denote the power or principle by which bodies mutually tend towards each other, without investigating the cause or action by which such effect is prodced.

There are commonly reckoned five kinds of attraction, viz. the attraction of *cohesion*, of *gravitation*, of *electricity*, of *magnetism*, and *chemical attraction*.

The attraction of *cohesion* is that by which the minute particles of matter are held together; and is only exerted at very small distances. The strength of this attraction being so different in different substances, is supposed by some to be the cause of their relative hardness or softness. This species of attraction may be observed in almost all the common operations of nature, and may be exemplified by many easily performed experiments.

Two leaden balls, having each a smooth surface, if strongly compressed together, will cohere almost as strongly as if united by fusion; and even two plates of glass, if the surfaces are even and dry, will require some force to separate them. By the same law of nature the particles of even fluid bodies, in which the attraction is necessarily weaker than in solid substances, indicate a disposition to unite. To this also may be referred what is called capillary attraction. The attraction of *gravitation* is one of the most universal principles in nature. It is that force by which distant bodies tend towards each other. By gravity, a stone dropped from a height falls to the earth; by it the heavenly bodies are kept in their orbits; and hereby all terrestrial bodies tend towards the centre of the earth. By it, the planets tend towards the sun, and towards each other, as well as the sun does to them. From this attraction arises all the motion, and consequently all the changes that take place, in the grander portions of the universe. By this heavy bodies descend, and light ones ascend; by this, projectiles are directed, and rains fall; rivers glide, the ocean swells, and the air presses upon different bodies.

The attraction of *electricity* is analogous to that of gravity in the property of acting upon bodies at a certain distance; but it differs from it in its operation being confined to a particular state of those bodies, that is, when excited by friction.

The attraction of *magnetism* only differs from that of gravity in its operations being limited to particular substances. The magnet is an ore of iron, and its property of attracting certain portions of that metal at moderate distances is well known.

The attraction of *combination*, or chemical elective attraction, is, in many respects, like that of cohesion; for it seems to depend on the minute particles of bodies being brought nearly into contact with each other. Chemical attraction may be, in fact, only the attraction of cohesion acting in an unresisting medium, since its distinguishing characteristic is, the disposition which bodies, in solution, indicate to unite with some substances, in preference to others.

ATTRIBUTES, in logic, are the predicates of any subject, or what may be affirmed or denied of any thing.

Attributes, in painting and sculpture, are symbols added to several figures, to intimate their particular office and character. Thus the eagle is an attribute of Jupiter; a peacock, of Juno; a caduce, of Mercury; a club, of Hercules; and a palm, of Victory.

ATTRITION, the rubbing or striking of bodies one against another, so as to throw off some of their superficial particles.

The grinding or polishing of bodies is performed by attrition, the effects of which are heat, light, fire, and electricity.

AVALANCHES, a name given in Switzerland and Savoy, to those prodigious masses of snow, which are precipitated with a noise like thunder from the mountains, destroying every thing in their course. They sometimes overwhelm whole villages.

AVAST, in the sea language a term requiring to stop, to hold, or to stay.

AUBLETIA, in botany, so named from M. Aublet, the author of the history of plants in Guiana a genus of the polyandria monogynia class and order.

AVENA, oats, a genus of the digynia order, belonging to the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calyx has a double valve, and the awn on the back is contorted. There are 25 species, six of which are natives of England. The original native place of the avena sativa, or common oats, cultivated in our fields, is almost totally unknown.

AVERAGE, in commerce, signifies the accidents and misfortunes which happen to ships and their cargoes, from the time of their loading and sailing to their return and unloading; and is divided into three kinds: viz. 1. The simple or particular average, which consists in the extraordinary expenses incurred for the ship alone, or for the merchandizes alone, such as the loss of cables, anchors, &c. 2. The large and common average, or those expenses incurred for the security of the merchandizes and vessels, and consequently borne by the ship and cargo. 3. The small averages, or the expenses of piloting a ship, a third of which must be charged to the ship, and two thirds to the cargo.

AVERRHOA, a genus of the decandria order, and pentagynia class of plants, in the natural method, ranking under the 14th order, gruinales. There are two species: the principal is the averrhoa carambola, called in Bengal the camrue, or camrenga, grows to the height of 14 feet, and its leaves, on being touched, move perceptibly. After sunset the leaves go to sleep, first moving down so as to touch each other by their under sides.

AUGITE, a mineral of the chrysolite family, found in basalt, sometimes in grains, but most commonly in crystals, mostly small and complete. Colour, blackish green, sometimes passing into leek green, and rarely to liver brown. Specific gravity 3.22 to 3.47. Before the blow-pipe it is, with difficulty, converted into a black enamel.

AVES, *birds*, among naturalists, the second class of animals, a race of creatures sufficiently distinguished from others in having the body covered with feathers, two feet, and two wings formed for flight. Birds have the mandible protracted and naked; and are destitute of external ears, lips, teeth, scrotum, womb, urinary vessel, or bladder, epiglottis, corpus callosum, or its fornix, and diaphragm. In the Linnæan system, birds are divided into six orders, viz. accipitres, or falcon kind; picæ, or pies; anseres, or geese and duck kind; grallæ, cranes, or waders; gallinæ, the poultry kind; and passeres, sparrows, or small birds.

AVIARY, a place set apart for feeding and propagating birds. It should be so large, as to give the birds some freedom of flight; and turfed, to avoid the appearance of foulness on the floor.

AVICENNA, a genus of plants, of the tetrandria monogynia class, the flower of which consists of a single petal; the fruit is a coriaceous capsule of one cell, containing one seed of an elliptic figure. There are three species, all natives of the West Indies.

AVOIRDUPOISE *weight*, a sort of weight used in England, of which the pound consists of sixteen ounces. The proportion of a pound avoirdupoise to a pound troy is as 17 to 14.

AURICLE, in anatomy, that part of the ear which is prominent from the head, called by many authors *auris externa*.

AURICLES *of the heart*. These are a kind of appendages of the heart at its base, and are distinguished by the names of the right and left. The right auricle is much larger than the left, and this is placed in the hinder, that in the anterior part. They are intended as diverticula for the blood, during the systole. Their substance is muscular, being composed of strong fibres, and their motion is not synchronous, but achronous with that of the heart. See Anatomy.

AURICULAR *medicines*, such as are used in the cure of distempers in the ear.

AURIGA, the *Waggoner*, in astronomy, a constellation of the northern hemisphere, consisting of 23 stars, according to Tycho; 40 according to Hevelius; and 66 in the Britannic Catalogue. This constellation is represented by the figure of an old man, in a posture somewhat like sitting, with a goat and her kids in his left hand, and a bridle in his right.

AURORA *borealis*, or Aurora *septentrionalis*, in physiology, the northern dawn or light, sometimes called streamers, is an extraordinary meteor, or luminous appearance, shewing itself in the night-time in the northern part of the heavens: and most usually in frosty weather. It is usually of a reddish colour, inclining to yellow, and sends out frequent coruscations of pale light, which seem to rise from the horizon in a pyramidal undulating form, and shoot with great velocity up to the zenith. The aurora borealis appears frequently in form of an arch, chiefly in the spring and autumn, after a dry year. The arch is partly bright, partly dark, but generally transparent

and the matter of which it consists is also found to have no effect on the rays of light which pass through it.

This kind of meteor, which is more uncommon as we approach towards the equator, is almost constant during the long winter, and appears with the greatest lustre in the polar regions. In the Shetland Isles, the "merry dancers," as the northern lights are there called, are the constant attendants of clear evenings, and afford great relief amidst the gloom of the long winter nights.

Various theories have been offered at different times for explaining the cause of this phenomenon, but the most correct of these appears to be that which refers it to electricity, which see.

AURUM. See GOLD.

AURUM MUSIVUM, or MOSAICUM, is a combination of tin and sulphur, which is thus made: Twelve ounces of tin are first melted; to this three ounces of mercury are then added: this amalgam is then triturated with seven ounces of sulphur, and three of muriate of ammonia. The powder is then put into a matrass bedded in sand, and kept for several hours in a gentle heat, after which, the heat must be increased. If the heat have been properly regulated, the golden-coloured scaly porous mass, called aurum musivum, will be found at the bottom of the vessel. This substance is used as a pigment for giving a golden colour to small statues or plaster figures. It is sometimes used also with melted glass to imitate lapis lazuli.

AUTOMATUM, or AUTOMATON, an instrument, or rather machine; which, by means of springs, weights, &c. seems to move itself as a watch, clock, &c. Such also were Archytus's flying dove, Regiomontanus's wooden-eagle, &c.

AUTUMN, the third season of the year, which begins on the day when the sun enters Libra. Autumnal signs in astronomy are Libra, Scorpio, and Sagittarius. Autumnal point is that part of the equinox from which the sun begins to descend towards the south pole.

AWL, or AUL, among shoemakers, an instrument wherewith holes are bored through the leather, to faciliate the stitching or sewing the same. The blade of the awl is usually a little flat and bended, and the point ground to an acute angle.

AUXILIARY *verbs*, in grammar, are such as help to form or conjugate others; that is, are prefixed to them, to form or denote the moods or tenses thereof: as *to have* and *to be*.

In the English language the auxiliary verb *am* supplies the want of passive verbs.

AXILLA, in anatomy, the arm-pit, or the cavity under the upper part of the arm. *Axilla*, in botany, is the space between the stems and leaves of plants.

AXIOM, in philosophy, is such a plain, self-evident, and received notion, that it cannot be made more plain and evident by demonstration, because it is itself better known than any thing that can be brought to prove it.

AXIS, in geometry, the straight line in a plane figure, about which it revolves, to produce or generate a solid: thus, if a semicircle be moved round its diameter at rest, it will generate a sphere, the axis of which is the diameter

AXIS, in astronomy. Axis of the world, an imaginary right line conceived to pass through the centre of the earth from one pole to the other, about which the sphere of the world, revolves in its diurnal rotation.

AXIS, in conic sections, a right line dividing the section into two equal parts, and cutting all its ordinates at right angles. See CONIC SECTIONS.

AXIS, in mechanics. The axis of a balance is that line about which it moves, or rather turns about. Axis of oscillation is a right line parallel to the horizon, passing through the centre about which a pendulum vibrates.

AXIS *in peritrochio*, one of the five mechanical powers, consisting of a peritrochium or wheel, and moveable together with it about its axis.

AXIS, in optics, is that ray, among all others that are sent to the eye, which falls perpendicularly upon it, and which consequently passes through the centre of the eye.

AXIS of a glass or lens, is a right line joining the middle points of the two opposite surfaces of the glass.

AXIS of incidence, in dioptrics, is a right line perpendicular in the point of incidence, to the refracting superficies, drawn in the same medium that the ray of incidence comes from.

AXIS of refraction is a right line drawn through the refracting medium, from the point of refraction, perpendicular to the refracting superficies.

AXYRIS, in botany, a genus of the triandria order, belonging to the monœcia class of plants, and in the natural method ranking under the twelfth order, holoraceæ. There are three species, all annual, and natives of Siberia.

AYE-AYE, the name given to a singular quadruped discovered in the island of Madagascar, ranked by Gmelin under the genus "Sciurus." This animal is remarkably gentle but slothful, living chiefly underground, and scarcely able to distinguish objects by the light of day. Its food consists of worms and insects.

AYENIA, *in botany*, a genus of the pentandria order and gynandria class of plants, in the natural method ranking under the 37th order columniferæ. There are four species all natives of the West Indies.

AZELIA, in botany, the American upright honey suckle, a genus of the monogynia order, and pentandria class of plants: in the natural method ranking under the eighteenth order, bicornes. There are seven species, the principal of which are, 1. Azalea undiflora, or red American upright honey suckle, which grows to the height of twelve feet. The flowers are red. 2. Azalea viscosa bears a white flower. It is a shrub. 3. Azalea Pontica is a native of Pontus, and bears beautiful fragrant yellow flowers.

AZIMUTH, in astronomy, an arch of the horizon, intercepted between the meridian of the place, and the azimuth, or vertical circle passing through the circle of the object, which is equal to the angle of the zenith formed by the meridian and vertical circle.

AZIMUTH, *magnetial*, an arch of the horizon intercepted between the vertical circle

passing through the centre of any heavenly body, and the magnetical meridian.

Azimuth *compass*, an instrument adapted to find, in a more accurate manner than by the common sea-compass, the magnetical amplitude, or azimuth of the sun or stars.

Azimuth *dial*, one whose style or gnomon is at right angles to the plane of the horizon.

Azimuth *circles*, called azimuths, or vertical circles, are great circles of the sphere, intersecting each other in the zenith and nadir, and cutting the horizon at right angles.

AZOTE, or **Nitrogen**, in chemistry, a substance hitherto considered as elementary, existing abundantly in nature, forming full three-fourths of the atmosphere. It is a peculiar and almost characteristic ingredient of animal matter, the basis of nitric acid, and one of the constituents of volatile alkali. *Pure azote is known only in the form of gas; it is then synonymous with the phlogisticated air of Scheele and Priestley, the atmospherical mephitis of Lavoisier, and the nitrogen gas of Chaptal.*

AZURE, among painters, the beautiful blue colour, with a greenish cast, prepared from the lapis lazuli, generally called ultramarine.

Azure, in heraldry, the blue colour in the arms of any person below the rank of a baron. In the escutcheon of a nobleman, it is called saphire; and in that of a sovereign prince, Jupiter.

AZYGOS, a vein rising within the left side of the thorax, but having none like it on the other side; whence its name.

B.

B, the second letter of the alphabet, the first consonant, and the first mute; this letter is formed in the voice by a strong and quick expression of the breath, and opening of the lips, and is therefore one of the labials; as a mute it has a middle power between the smooth sound of P, and the rougher sound of F and V.

B is often used as an abbreviation: thus in music B stands for the tone above A, as $B^{\flat}$, or $^{\flat}B$, does for B flat, or the semi-tone major above A: B also stands for bass, and B. C. for *basso continuo*, or thorough bass. As a numeral, B was used by the Greeks and Hebrews to denote 2; but among the Romans, for 300, and with a dash over it (thus $\bar{B}$) for 3000. B.A. signifies Bachelor of Arts; B.L. Bachelor of Laws; and B.D. Bachelor of Divinity.

BABOON, the name of that tribe of apes which have short tails. See **Simia**.

BACCHARIS, in botany, *ploughman's spikenard*, a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ discoides. There are nine species, all natives of warm climates; the two following are the principal. viz. Baccharis halimifolia, or Virginia groundsel tree. 2. Baccharis ivæfolia, or African groundsel tree.

BACHELOR, or **Batchelor**, a man who still continues in the state of celibacy, or who was never married, and who, in certain cases, is subject to a double tax.

Bachelors, in a university sense, are persons that have attained to the bacca-laureat; or who have taken the first degree in the liberal arts and sciences. Before a person can be admitted to this degree at Oxford, it is necessary that he study there four years; three years more may entitle him to the degree of Master of Arts; and in seven years more he may commence Bachelor of Divinity.

BACK, in brewing a large flat vessel in which the wort is put to stand and cool before boiling. The ingredients of beer pass through three kinds of vessels; they are mashed in one, worked in another, and cooled in a third, called backs or coolers.

BACOPA, in botany, a genus of the pentandria monogynia class and order. There is but one species, an aquatic plant of Cayenne, celebrated by the inhabitants for its efficacy in curing burns.

BACTRIS, in botany, a genus of the class and order monœcia hexandria. This genus is classed among the palms: there are two species, the majus and minus, both natives of Carthagena, where the fruit is eaten.

BADGE, in naval architecture, an ornament placed on the outside of small ships, very near the stern, containing either a window or the representation of one.

BÆCKIA, in botany, so named in honour of Abraham Bæck, the intimate friend of Linnæus, who received this plant from him; of the octandia monogynia class and order. Natural order, calycanthemæ; Onagreæ Jussieu. Essential character: calyx, funnel form, five-toothed; corolla, five-petalled; capsule globular, four-celled, crowned. It is a native of China, and called there tiongina.

BAGGAGE, in military affairs, denotes the clothes, tents, utensils of divers sorts, provisions, and other necessaries belonging to an army.

BAGPIPE, a musical instrument of the wind kind, used in country places, in the north: it consists of two parts; the first a leathern bag, which blows up like a foot-ball by means of a port-vent or tube fitted to it, and stopped by a valve: the other part consists of three pipes, the first called the drone, and the second the little pipe, which pass the wind out only at the bottom; the third has a reed, and is played on by compressing the bag under the arm, when full, and opening or stopping the holes, which are eight, with the fingers. The little pipe is ordinarily a foot long; that played on thirteen inches; and the port-vent six.

BAIL, in law, the setting at liberty one arrested, upon an action either civil or criminal, upon sureties taken for his appearance at a day and place assigned. Common bail is a matter of course, being nothing but a mere form upon appearance, after personal service of the writ, and notice to appear upon the defendant.

Special bail, are two or more persons, who, after the arrest, undertake, in a certain sum, to insure the defendant's appearance at the return of the writ; this obligation is called the bail-bond.

BAILIFF, a keeper, or protector. Hence the sheriff is considered as bailiff to the crown: and the county of which he has the care, and in which he is to execute the king's writ, is called his bailiwick; so also his officers who execute writs, warrants, &c. are called bailiffs.

BAILIWICK, that liberty which is exempted from the sheriff of the county, over which liberty the lord thereof appoints his own bailiff, with the like power within his precinct as an under-sheriff exercises under the sheriff of the county.

BALÆNA, the whale, a genus of the mammalia class, and of the order of ceti. The balæna instead of teeth has a horny plate on the upper jaw, and a double fistula or pipe for throwing out water. There are four species, viz. 1. Balæna bo-ops, the pike-headed whale, which has a double pike in its snout, three fins, and a horny ridge on its back. It frequents the northern seas, and takes its name from the shape of the nose which is more narrow and sharp-pointed than on other whales. 2. Balæna musculus has a double pipe in its front, and three fins; and the under jaw is wider than the upper. It frequents the shores of Scotland, and feeds on herrings. 3. Balæna mysticetus, the great Greenland whale, has no fin on the back. It is sometimes above ninety feet in length. The head is one-third of the size of the fish: and the under lip is much broader than the upper. The tongue is composed of a soft spongy fat, which will yield above five barrels of oil. The gullet does not exceed four inches. In the middle of the head are two orifices through which it spouts water to a considerable height and with great noise. The eyes are towards the back of the head. The sense of hearing in the whale is very acute, though the external ear is not perceptible. What is termed whalebone adheres to the upper jaw, and consists of thin parallel laminæ, some of which are four yards long. The real bones of the whale are hard, porous, and full of marrow. The tail is broad, and with it the animal gives a terrible blow. The colour of the whale is various, the back of some being red, the belly white, some are black, some mottled, and others brown or white. The scarf skin is smooth, but that which covers the blubber is an inch thick. The teats of the female are on the lower part of the belly: they breed only once in two years; the whale never produces above two young ones at a time, and generally but one. The young continues a year at the breast, during which time the sailors call them *short heads*. At the age of two years they are name *stunts*, and from that time they are called *skull fish*. To what age they live is unknown. The food of the great whale is a sea insect, called the medusa, or sea blubber. 4. Balæna physalus, or fin-fish, is distinguished from the common whale by a fin on the back, near the tail. It is about the length of the former, but more slender. Its bone is of little value, and the blubber is inconsiderable. It is a fierce and swift fish, on which account the seamen neglect it; but the Greenlanders hold it in estimation for the flesh. It blows water with more violence, and to a greater height than the common whale. It feeds on herrings, and other small fish. The whale has a terrible enemy in the sword fish, which wounds it in various places, while the enormous animal endeavours to strike it with its tail, but generally without effect. There is also a shell fish which attaches itself to the body of the whale, and feeds on the fat, whence it is called the whale louse. But the most powerful enemy of the whale except man, is the orien or killer. A number of these surround the animal as dogs attack a bull. While some tear it with their teeth before, others get behind it, till the whale is torn down, when they seize upon its tongue, which is the only part they devour.

BALANCE, in mechanics, one of the simple powers which serves to find out the equality or difference of weight in heavy bodies.

BALANCE *of trade*, in commerce, the equality between the value of the commodities bought of foreigners, and the value of the native productions transported into other nations.

BALE, in commerce, is said of merchandizes packed up in cloth, and corded round very tight, in order to keep them from breaking, or preserve them from the weather.

A bale of cotton yarn is from three to four hundred weight; of raw silk, it is from one to four hundred; of dowlas, three, three and a half, or four pieces.

BALISTER, a genus of fishes of the order cartilaginei. There are twenty-four species, all remarkable for the splendour of their colours.

BALL, in the military art, comprehends all sorts of bullets for fire-arms, from the cannon to the pistol.

Cannon-balls are made of iron; musket-balls, pistol-balls, &c. are of lead. The experiment has been tried of iron balls for pistols and fusees, but they are justly rejected, not only on account of their lightness, which prevents them from flying straight, but because they are apt to furrow the barrel of the pistol, &c.

BALL *and socket*, is an instrument made of brass, with a perpetual screw, so as to move horizontally, vertically, and obliquely; and is generally used for the managing of surveying instruments, and astronomical instruments.

BALLAST, a quantity of stones, gravel, or sand, laid in a ship's hold, to make her sink to a certain depth into the water and sail upright, rendering her of a prodigious weight.

BALLET, in music, a theatrical representation of some tale or fable told in dance, or metrical action, accompanied with music. The artist who invents and superintends the rehearsal and performance of the ballet is called the ballet-master.

BALLISTA, in antiquity, a military machine used by the ancients in besieging cities, to throw large stones, darts, and javelins. It resembled our cross-bows though much larger, and superior in force.

BALLOON, in a general sense, signifies any spherical hollow body, of whatever substance it may be made, or for whatever purpose it be employed. See AEROSTATION.

BALLOTA, in botany, a genus of the didynamia gymnospermia class and order. Natural order of the verticillatæ, or labiatæ. Essen-

tial character: calyx salver-shaped, five-toothed, ten-streaked; corolla, upper-lip crenate, concave. There are six species. The European sorts, being common weeds, are never introduced into gardens.

BALLS, or **Ballets**, in heraldry, a frequent bearing in coats of arms, usually denominated according to their colours, bezants, plates, hurts, &c.

BALM, or **Baum**, in botany. See Melissa.

BALNEUM, a term used by chemists to signify a vessel filled with some matter, as sand, water, or the like, in which another is placed that requires a more gentle heat than the naked fire.

BALSAM, or **Native Balsam**, an oily, resinous, liquid substance, flowing either spontaneously, or by means of incision, from certain plants of sovereign virtue in the cure of several disorders. The principal balsams are benzoin, storax, styrax, balsam of Peru, and balsam of Tolu.

BALSAMICS, in pharmacy, softening, restoring, healing, and cleansing medicines, of gentle attenuating principles.

BALTIMORA, in botany, a genus of the polygamia necessaria order, and syngenesia class of plants. There is but one species, a native of Maryland.

BAMBOE, or **Bambou**. See Arundo.

BAMBUSA, in botany. See Arundo.

BANANA, in botany. See Musa.

BAND, in architecture, a general name for any flat, low member, or moulding, that is broad, but not very deep.

BANDEROLL, a little flag in form of a guidon, extended more in length than breadth, used to be hung out on the masts of vessels, &c.

BANISHMENT is the quitting of the realm: there are two kinds of it, one voluntary, called abjuration, and the other upon compulsion for some offence.

BANK, in commerce, the name usually given to establishments which receive the money of private persons, to keep it in security or improve it at interest, till those to whom it belongs have occasion to draw it out again. They are generally formed by a number of monied persons, who, for carrying on the business of exchanging or dealing in bullion, money, and bills, advance a considerable sum as a joint capital, which also forms a security to those who deposit money with them. The convenience of such institutions in facilitating commercial transactions, has caused them to be erected in almost every considerable city of Europe. The bank of Venice was established bout the year 1157, the bank of Genoa in 1345, the bank of Amsterdam in 1609, the bank of Hamburgh in 1619, the bank of Rotterdam in 1635, the bank of England in 1694, the bank of Scotland in 1695, the bank of France in 1716.

BANKER, a person who traffics and negociates in money, who receives and remits money from place to place, by commission from correspondents, or by means of bills or letters of exchange.

BANKRUPT, a trader whom misfortune or extravagance has induced to commit an act of bankruptcy. The benefit of the bankrupt laws is allowed to none but actual traders, or such as buy and sell, and gain a livelihood by so doing.

BANKSIA, in botany, so called in honour of Sir Joseph Banks, who first discovered it in his voyage with Captain Cook; a genus of the tetrandria monogynia class and order. Natural order of aggregatæ.

BANNER denotes either a square flag, or the principal standard belonging to a prince.

BANNERET, an ancient order of knights, or feudal lords, who, possessing several large fees, led their vassals to battle under their own flag, when summoned thereto by the king.

This order is certainly most honourable, as it never was conferred but upon some heroic action performed in the field.

BANNISTERIA, in botany, a distinct genus of plants, according to Linnæus; but accounted only a species of clematis by other botanists.

It belongs to the decandria trigynia class; its flower consists of five very large, orbicular petals; and its fruit is composed of three unilocular capsules, running into long alæ.

BANTAM *work*, a kind of painted or carved work, resembling that of Japan, only more gaudy.

BAR, in courts of justice, an inclosure made with a strong partition of timber, where the council are placed to plead causes. It is also applied to the benches, where the lawyers or advocates are seated, because anciently there was a bar to separate the pleaders from the attornies and others. Hence our lawyers, who are called to the bar, or licensed to plead, are termed barristers, an appellation equivalent to licentiate in other countries.

BARALIPTON, among logicians, a term denoting the first indirect mode of the first figure of syllogism. A syllogism in baralipton, is when the two first propositions are general, and the third particular, the middle term being the subject in the first proposition, and the predicate in the second. Thus,

Ba Every evil ought to be feared:
Ra Every violent passion is an evil;
Lip Therefore something that ought to be feared is a violent passion.

BARBA, in botany, *a beard*, a species of down with which the surface of some plants is covered. The term was invented by Linnæus, without precise explanation; it seems however to signify a tuft of hairs terminating the leaves.

BARBACAN, or **Barbican**, an outer defence, or fortification to a city or castle, used especially as a fence to the city, or walls; also, an aperture made in the walls of a fortress, to fire through upon the enemy. It is also used as a watch-tower to descry the approach of the enemy; and it sometimes denotes a fort at the entrance of a bridge, or the outlet of a city having a double wall with towers.

BARBARA, among logicians, the first mode of the first figure of syllogisms.

A syllogism in barbara, is one of which all the propositions are universal, and affirmative; the middle term being the subject of the first proposition, and attribute in the second.

BARBED *and* **Crested**, in heraldry, an appellation given to the combs and gills of a cock, when particularized for being of a different tincture from the body.

BARBER, one who makes a trade of shaving the beards of other men, for money. Besides curling the hair, and shaving, the ancient barbers trimmed the nails. Formerly some musical instrument was part of a barber's stock

in trade; and it was customary for persons above the common rank to resort to his shop, either for surgical operations, or for shaving, &c. The music was for the amusement of the waiting customers, and answered the same purpose as a newspaper in modern times. Barbers were uniformly bleeders; and the *pole* now used as a sign, was a representation of the staff which was put into the hand of a person undergoing the operation of phlebotomy. The white band which surrounds it is designed to represent the fillet that binds up the arm.

BARILLA, a kind of Spanish alkaline salt used in the glass trade. It is procured by burning to ashes several plants of the kali kind. See Soda.

BARIUM, the name given by the discoverer, Sir H. Davy, to the metallic basis of the earth barytes. It is obtained by forming pure barytes into a paste with water, and placing the mass on a plate of platinum. A small cavity is then formed in the middle of the barytes, into which a globule of mercury is to be placed. This preparation is then subjected to the action of the voltaic battery, by touching the mercury with the negative wire, and the platinum with the positive wire. In a short time an amalgam is formed consisting of mercury and barium, which, on being distilled in a curved glass tube, free from lead, parts with the mercury, while the barium remains. This metal is of a dark grey colour, inferior in lustre to cast-iron, and fusible at a red heat.

BARK, in the anatomy of plants, the exterior part of trees, corresponding to the skin of an animal.

Bark, in navigation, a little vessel with two or three triangular sails; but, according to Guillet, it is a vessel with three masts, viz. a main-mast, fore-mast, and mizen-mast.

Bark, or *Jesuist's Bark*. See Cinchona.

BARLERIA, a genus of the angiospermia order, and didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There are eleven species, all natives of the warm parts of America.

BARLEY. See Hordeum.

Barley-corn, the least of our long measures, being the third of an inch.

BAROMETER, a philosophical instrument for measuring the weight of the atmosphere. The barometer may be said to be the invention of Torricelli, who, observing that a column of water of about 33 feet was equal in weight to one of air of the same base, concluded that a column of mercury of only 29½ inches would be so too, such a column of mercury being equal in weight to 33 feet of water.

The common barometer is a glass tube about two-tenths of an inch in diameter, and its length at least thirty-one inches. This tube is filled with mercury so as not to have any air over it, the maker placing his finger on the end, immerses it in a bason of quicksilver, and then takes his finger away. The quicksilver in the tube, by its own weight endeavours to descend into that of the bason: but the external air pressing on the surface of the quicksilver in the bason without, and no air being in the tube at top, the quicksilver will continue in the tube, being raised by the air on the surface in the bason below. The usual range of the barometer in this country is from twenty-eight to thirty-one inches; when the air is pure and heavy, it raises the mercury to nearly thirty-one, and when light and full of vapours, it falls to nearly twenty-eight. In fine, *dry* weather, the air is rendered pure, free from all light vapours, and is consequently extremely heavy, so that it presses up the quicksilver. In moist rainy weather the atmosphere being charged with vapours, clouds, and fogs, the air is then sensibly lighter, and presses upon the quicksilver with less force. When high winds blow, the atmosphere is light, and the quicksilver generally is low, and it rises higher in cold weather than in warm. During frost, the air is purest and heaviest, and the barometer rises to its highest points. This instrument is also serviceable in measuring the height of mountains. In ascending mountains, quicksilver is found to sink about a tenth of an inch in ninety feet; so that if the quicksilver fall an inch, we have ascended near nine hundred feet; but this is subject to variations, from change of temperature and other causes, which render various corrections necessary. The general method, however, of determining altitudes by the barometer and thermometer is extremely useful and convenient; and ingenious rules are given by Dr. Hutton, Dr. Gregory, Sir Henry Englefield, and others, to facilitate the computation.

BARON, a degree of nobility next below a viscount, and above a baronet.

Barons *of the cinque-ports* are members of the house of commons, elected by the five ports, two for each port.

Baron *and* **Feme**, in law, a term used for husband and wife, who are deemed but one person.

Baron *and* **Feme**, in heraldry, is when the coats of arms of a man and his wife are borne per pale in the same escutcheon, the man's being always on the dexter side, and the woman's on the sinister.

BARONET, a modern degree of honour which is hereditary, and has the precedence of all knights, except those of the garter, bannerets, and privy-counsellors.

BARONY, the honour and territory which gives title to a baron, whether he is a layman or a bishop.

Barony, in Ireland, the name of the divisions of the counties, answering to English hundreds.

BARRATRY, in a ship-master, is his cheating the owners. If goods delivered on shipboard are embezzled, all the mariners ought to contribute to the satisfaction of the party who lost his goods, by the maritime law; and the cause is to be tried in the admiralty.

BARREL, a measure of liquids. The English barrel, wine-measure, contains the eighth part of a tun, the fourth part of a pipe, and one-half of an hogshead; that is, it contains thirty-one gallons and a half: a barrel, beer-measure, contains thirty-six gallons. The barrel of beer, vinegar, or liquor preparing for vinegar, ought to contain thirty four gallons, according to the standard of the ale quart.

Barrel also denotes a certain weight of several merchandizes; thus a barrel of Essex butter weighs 106lbs, and of Suffolk butter 256lbs. The barrel of herrings ought to contain 32 gallons wine measure, containing about a thousand herrings. The barrel of salmon must contain 42 gallons. The barrel of eels the same. The barrel of soap must weigh 256lbs.

BARRERIA, in botany, a genus of the syngenesia monogamia class and order. The essential character is, calyx, five-toothed, very small; corolla, five-parted; style, short; stigma, trifid. There is but one species, a tree of Guiana, which rises to the height of 40 or 50 feet.

BARRICADE, or BARRICADO, a warlike defence, consisting of empty barrels and such like vessels filled with earth, stones, carts, trees cut down, against an enemy's shot, or assault; but generally trees cut with six faces, which are crossed with battoons as long as a half-pike, bound about with iron at the feet.

BARRIER, in fortification, a kind of fence made at a passage, retrenchment, &c. to prevent the entrance of either horse or foot.

BARINGTONIA, in botany, a genus of the polyandria order, and monadelphia class of plants, the characters of which are: female, the calyx diphyllous above, with a drupa, which it crowns; and the seed is a quadrilocular nut. There is is but one species, a native of China, and Otaheite.

BARRISTER, in common law, a person qualified and empowered to plead the cause of clients in courts of justice. Barristers are distinguished into outer and inner: outer barristers are those of five years' standing, and who plead without the bar: inner barristers are those who, being king's counsel, have the privilege of pleading within the bar.

BARROW, a name usually given to those hillocks or mounds of earth which were anciently raised over the bodies of deceased heroes, and persons of distinguished character. These are considered by some antiquarians as the most ancient sepulchral monuments in the world.

BARRULET, in heraldry, the fourth part of the bar, or the one half of the closset: an usual bearing in coat-armour.

BARRULY, in heraldry, is when the field is divided bar-ways, that is, across from side to side, into several parts.

BARRY, in heraldry, is when an escutcheon is divided bar-ways, that is, across from side to side, into an even number of partitions, consisting of two or more tinctures, interchangeably disposed.

BARRY-*bendy* is when an escutcheon is divided evenly, bar and bend-ways, by lines drawn transverse and diagonal, interchangeably varying the tinctures of which it consists.

BARRY-*pily* is when a coat is divided by several lines drawn obliquely from side to side, where they form acute angles.

BARTERING, in commerce, the exchanging of one commodity for another, or the trucking wares for wares, among merchants. Bartering was the original and natural way of commerce, there being no buying till money was invented, though in exchanging, both parties are buyers and sellers.

BARTSIA, in botany, so named from Dr. Bartsch, the intimate friend of Linnæus, a genus of the didynamia angiospermia class of plants, whose flower consists of one petal, having the upper lip longest; the seeds are numerous, small, angular, and inclosed in capsules. There are five species.

BARYTES, in mineralogy, an earth discovered by Scheele in 1774: he gave it the name of terra ponderosa, from its weight, and Kirwan that of barytes, by which it is now generally called. Its taste is harsh and caustic, and it is a powerful poison. It tinges vegetable blues green, and decomposes fixed bodies; it has no action on metals; but it readily combines with several metallic oxides.

BASALTES, in natural history, a kind of stone of a fine texture, resembling polished steel. It is never found in strata, but standing up in the form of regular angular columns composed of a number of joints, fitted to each other with the greatest exactness. The grandest specimen in the world, is that called the Giant's Causeway in Ireland, where it rises far up the country, runs into the sea, and rises again on the opposite shore. Basalt is used in building and paving, also as an ingredient in the manufacture of glass bottles; when calcined and pulverized it makes excellent mortar, which hardens under water.

BASE, in geometry, the lowest side of the perimeter of a figure; thus, the base of a triangle is properly the lowest, or that which is parallel to the horizon.

BASE *of a solid figure*, the lowest side, or that on which it stands.

BASE *of a conic section*, a right line in the hyperbola and parabola, arising from the common intersection of the secant plane, and the base of the cone.

BASE, in architecture, is the lower part of a column and pedestal.

The base of a column is that part between the shaft and the pedestal, if there be one; or, if there be none, between the shaft and the plinth.

BASE, in fortification, the exterior side of the polygon, or that imaginary line which is drawn from the flanked angle of a bastion to the opposite angle.

BASE, in gunnery, the least sort of ordnance, the diameter of whose bore is 1¼ inch, weight 200 pounds, length 4 feet, load 5 pound, shot 1½ pound weight, and diameter 1⅛ inch.

BASE *line*, in perspective, the common section of a picture, and the geometrical plane.

BASE, or **BASIS**. By this term modern chemists express either species or families of saline matters, which differ with regard to the acid, but agree as to the alkali, earth, or metallic oxide, which they contain.

BASE, in law. Base estate, such as base tenants possess. Base tenure, the holding by villenage or other customary service. Base fee, is to hold in fee at the will of the lord Base court, any court not of record.

BASELLA, CLIMBING NIGHTSHADE, from Malabar, a genus of the pentandria class, and trigynia order of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is wanting; the corolla is seven-cleft; there is one seed. There are four species, but the two following are the principal:

1. Basella alba, with oval leaves, and small flowers and fruit.

2. Basella rubra, with red leaves and simple footstalks, has thick, strong, succulent stalks and leaves, which are of a deep purple colour.

BASEMENT, in architecture, a base con-

tinued a considerable length, as round a house, room, &c.

BASKETS are made of rushes, splinters, or willows, which last, according to their manner of growth, are called osiers and sallows.

When the osiers are cut down, those that are intended for white work, such as baskets used in washing, are to be stripped of their bark or rinds while green, by a sharp instrument fixed into a block: before they are worked up, they must be soaked in water, which gives them flexibility.

Hampers and other coarse work are made of osiers without any previous preparation except soaking.

The ancient Britons were noted for their ingenuity in making baskets, which they exported in large quantities. They were of very elegant workmanship, and bore a high price.

BASS, in music, that part of a concert which is most heard, which consists of the gravest and deepest sounds, and which is played on the largest pipes or strings of a common instrument, as of an organ, lute, &c. or on instruments larger than ordinary, for that purpose, as bass-viols, bassoons, bass hautboys, &c. The bass is the principal part of a musical composition, and the foundation of harmony; for which reason it is a maxim among musicians, that when the bass is good, the harmony is seldom bad.

Bass, *counter*, is a second or double bass, where there are several in the same concert.

BASSIA, in botany, a genus of the dodecandria class of plants, and monogynia order, the characters of which are: calyx, quadriphyllous; corolla, octofid, and tube, inflated; stamina, 16; drupe, quinquespermous. There are three species, natives of Malabar.

BASSOON, a musical instrument of the wind sort, blown with a reed, furnished with eleven holes, and used as a bass in a concert of hautboys, flutes, &c.

BASSORIA, a genus of the penandria monogynia class and order: calyx, five-cleft, spreading, with a short tube; berry, ovate, knobbed, and many-seeded. There is but one species, an herbaceous plant of Guiana.

BASSO-*relievo*, or Bass-relief, a piece of sculpture, where the figures do not project far above the plane on which they are formed. Whatever figures are thus cut, are said to be done in relief, or relievo; and when the work is low, flat, and but a little raised, it is called low relief: when a piece of sculpture, or a medal, has its figure raised so as to be well distinguished, it is called bold, and we say its relief is strong.

BASTARD, a natural child, or one born out of wedlock, consequently illegitimate. The incapacity of a bastard consists in this, that he cannot be heir to any one; nor can he have heirs but of his own body. A bastard may, however, be made legitimate by an act of parliament.

BASTION, in the modern fortification, a mass of earth, faced usually with sods, sometimes with brick, and rarely with stone, standing out from a rampart. A bastion consists of two faces and two flanks; the faces include the angle of the bastion; and their union makes the saliant angle, called also the angle of the bastion; and the union of the two faces to the two flanks makes the side-angles, called also the shoulders, or epaules; and the union of the two other ends of the flanks to the two curtains makes the angles of the flanks. See Fortification.

BASTON, or Batoon, in heraldry, a kind of bend, having only one third of the usual breadth.

BAT. See Vespertilio.

BATIS, in botany, a genus of the tetrandria order, and diœcia class of plants; of the male, the amentum is four-ways imbricated, and both the calyx and corolla are wanting: of the female, the amentum is ovate; the involucrum diphyllous; calyx and corolla wanting; the stigma is bilobate and sessile; the berries condunate, and four-seeded. There is but one species, a native of Jamaica.

BATTALION, a body of infantry, ranged in form of battle, and ready to engage.

A battalion usually contains from 500 to 800 men; but the number it consists of is not determined.

BATTEN, a name that workmen give to a scantling of wood from two to four inches broad, and about one inch thick; the length is undetermined.

BATTERY, in military affairs, implies any place where cannon or mortars are mounted, either to attack the forces of the enemy, or to batter a fortification: hence batteries have various names, according to the purposes they are designed for.

Battery, in law, the striking, beating, or offering any violence to another person, for which damages may be recovered. But if the plaintiff made the first assault, the defendant shall be quit, and the plaintiff amerced to the king for his false suit.

BATTLE, in the military art, has ever been the last resource of good generals. A situation where chance and accident often baffle and overcome the most prudential and most able arrangements, and where superiority of numbers by no means ensures success, is such as is never entered into without a clear necessity for so doing.

Battle *array*, or line of *battle* is the form of drawing up the army for an engagement: this generally consists of three lines, viz. the front, the rear, and the reserve.

Battle, *naval*, the same with a sea-fight, or engagement between two fleets of men of war. Before a naval battle every squadron usually subdivides itself into three equal divisions, with a reserve of certain ships out of every squadron to bring up their rear.

BATTLEMENTS, in architecture, are indentures or notches in the top of a wall or other building, in the form of embrasures, for the sake of looking or firing through them.

BAUHINIA, *mountain ebony*, a genus of the monogynia order, and decandria class of plants, ranking in the natural method under the thirty-third order lomentaceæ. There are thirteen species, all trees and shrubs, propagated by seeds. The principal are, 1. Bauhinia aculeata with a prickly stalk. It is common in America and the West Indies, where it is called the savin tree. 2. Bauhinia acuminata, with oval leaves. It is a native of both the East and West Indies. The wood is hard with

black veins. 3. Bauhinia divaricata, with oval leaves, whose lobes spread different ways. It grows in Jamaica. 4. Bauhinia tomentosa, with heart-shaped leaves, is a native of Campeachy, and grows to the height of fourteen feet.

BAYONET, in the military art, a short dagger made to fit on the muzzle of a firelock, and so fixed that the soldier may discharge his piece while it is on, and be ready to charge.

BAYS, in commerce, a sort of open woollen stuff, having a long nap, sometimes frized, and sometimes not. It is chiefly manufactured in Essex.

BEACON, a public signal, to give warning against rocks, shelves, invasions, &c.

The corporation of the Trinity-house are empowered to set up beacons wherever they shall think necessary; and if any destroy or take them down, he shall forfeit 100*l.* or be *ipso facto*, out-lawed.

BEAD, in architecture, a round moulding on the edge of a piece of stuff in the Corinthian and Roman orders. Also an ornament made of glass, &c. for necklaces. *Bead proof*, among distillers, is a fallacious mode of determining the strength of spirits from the continuance of the bubbles or beads raised on the surface.

BEAGLE. See *Canis*.

BEAM, in architecture, the largest piece of wood in a building, which lies across the walls, and serves to support the principal rafters of the roof, and into which the feet of these rafters are framed. No building has less than two of these beams, viz. one at each end.

Beams *of a ship*, are the great main cross-timbers which hold the sides of the ship from falling together, and which also support the decks and orlops. The main beam is next the main-mast, and from it they are reckoned by first, second, third, beam, &c. The greatest beam of all is called the mid-ship beam.

Beam-*compass*, an instrument consisting of a square wooden or brass beam, having sliding sockets, that carry steel or pencil points: they are used for describing large circles, where the common compasses are useless.

Beam, in heraldry, the term used to express the main horn of a hart or buck.

BEAN. See Vicia, and Phaseolis.

BEAR. See Ursus.

Bear, in astronomy, a name given to two constellations, called the greater and lesser bear, or ursa major, and ursa minor.

Bear, a species of barley cultivated in Scotland and Ireland, and the northern parts of England. It is not esteemed so good for malting as the common barley.

Bear, in heraldry. He that has a coat of arms is said to bear in it the several charges or ordinaries that are in his escutcheon.

BEAR'S *breech*. See Acanthus.

BEARER, in architecture, a post, or brick wall, trimmed up between the two ends of a piece of timber, to shorten its bearing, or to prevent its bearing with the whole weight at the ends only.

BEARING, in navigation and geography, the situation of one place from another, with regard to the points of the compass.

Bearing, in the sea language: When a ship sails towards the shore, before the wind, she is said to bear in with the land or harbour. To let the ship sail more before the wind, is to bear up To put her right before the wind, is to bear round. A ship that keeps off from the land, is said to bear off. When a ship that was to windward comes under another ship's stern, she is said to bear under her lee, &c.

BEAT, in music, a transient grace note, struck immediately before the note it is intended to ornament. The beat always lies half a note beneath its principal, and should be heard so closely upon it, that they may almost seem to be struck together.

BEAVER. See Castor.

BECHERA, in botany, a genus of the pentandria digynia class and order. Calyx, five cleft, superior, with a globular tube; coral, five-petalled; capsule, two-celled, two-valved. One species.

BED, in masonry, a course or range of stones; and the joint of the bed is the mortar between two stones placed over each other.

BED-*chamber, lords of*, in the British customs, 14 lords who attend in their turns, each a week, during which time they lie in the king's bed-chamber, and wait on him when he dines in private.

BEDOUINS, tribes of Arabs, who live in tents, and are dispersed all over Arabia, Egypt, and the north of Africa.

BEE, in zoology. See Apis.

BEECH. See Fagus.

BEER. See Brewing.

BEESTINGS, a term used by country-people for the first milk taken from a cow after calving.

BEET. See Beta.

BEETLE. See Scarabæus.

Beetle also denotes a wooden instrument for driving piles, &c.

It is likewise called a stamper, and by paviors a rammer.

BEGONIA, a genus of plants of the monœcia polyandria class and order, whose characters are: the male flower has no calyx, but many petals; the female is of the rosaceous kind, and composed of several petals in a circular form, on a foliated cup, which becomes a trigonal alated capsule, containing small seeds. There are thirteen species, chiefly stove-plants.

BEJARIA, a genus of plants of the dodecandria monogynia class and order: calyx is seven cleft; petals, seven; stamina, fourteen; berry, seven-celled, and many seeded. The species are two, one a tree, and the other a shrub, natives of New Grenada.

BELL, a well-known machine, ranked by musicians among the musical instruments of percussion. The music of bells is altogether melody; but the pleasure arising from it consists in the variety of interchanges, and the various successions and general predominance of the consonances in the sounds produced. The metal of which a bell is made, is a composition of tin and copper, or pewter and copper; the proportion one to the other is almost 20 pounds of pewter, or 23 pounds of tin, to 100 weight of copper.

The sound of a bell consists in a vibratory motion of its parts, much like that of a musical chord. The stroke of the clapper must necessarily change the figure of the bell, and of a round make it oval; but the metal having a

great degree of elasticity, that part will return back again which the stroke drove farthest off from the centre, and that even some small matter nearer the centre than before; so that the two parts which before were extremes of the longest diameter, do then become those of the shortest; and thus the external surface of the bell undergoes alternate changes of figure, and by that means gives that tremulous motion to the air, in which the sound consists.

BELLA-*donna*. See AMARYLLIS and ATROPA.

BELLES *Lettres*, a word absurdly introduced from the French, and noted here only to reprobate the contemptible practice of debasing the simple majesty of our native language, by wretched Gallicisms. The French writers themselves have no determinate idea affixed to this phrase; some applying it to polite literature only, and some extending it to the whole scope of human learning, even to mathematics.

BELLIS, the daisy, a genus of the syngenesia class, and polygamia superflua order of plants; in the natural method ranking under the 49th order, compositæ discoidæ. There are two species, and many varieties. 1. Bellis annua is a low annual plant, which grows on the Alps, and the hilly parts of Italy. 2. Bellis perennis, or common daisy, grows naturally in pasture lands. The varieties of the garden daisy are the red and white; the double variegated; the childing, or hen and chicken daisy, and the cockscomb daisy.

BELLIUM, a genus of the syngenesia, polygamia superflua class and order. The essential character is; cal. with equal leaflets; seeds conic, with chaffy eight-leafed crown, and awned down; recept. naked. There are two species, natives of Italy and the Levant, in many respects resembling the daisy in habit and appearance.

BELLONIA, a genus of the monogynia order, and pentandria class of plants. Flower wheel-shaped; germen under the receptacle of the flower which afterwards becomes a turbinated seed-vessel ending in a point having one cell filled with round seeds. There are two species. 1. Bellonia aspera or shrubby bellonia, which is common in the West Indies. 2. Bellonia spinosa, a native of Hispaniola.

BELLOWS, a machine so contrived as to expire and respire the air alternately by enlarging and contracting its capacity. The action of bellows depends on this: that the air which enters is compressed when they are closed, and flows out of the pipe with a velocity proportioned to the force by which it is compressed. The bellows of smiths and founders are worked by means of a rocker. The bellows of a large organ are worked by a man called the blower; but in small organs by the foot of the player.

BELLY, in anatomy, the same with what is more usually called abdomen, or rather the cavity of the abdomen. See ANATOMY.

BENCH, FREE, signifies that estate in copybold lands, which the wife, being espoused a virgin, has, after the decease of her husband, for her dower, according to the custom of the manor.

BEND, in heraldry, one of the nine honourable ordinaries, containing a third part of the field when charged, and a fifth when plain

BENDING, in the sea language, the tying two ropes or cables together: thus they say, bend the cable; that is, make it fast to the ring of the anchor: bend the sail, make it fast to the yard.

BENDS, in a ship, the same with what are called wails, or wales; the outmost timbers of a ship's side, on which men set their feet in climbing up.

BENZOIN, a dry and solid resin, brought from the East Indies, particularly from the kingdom of Siam, and the islands of Java and Sumatra. It is brittle, and breaks vitreous. When rubbed, it emits a fragrant odour; and hen heated sufficiently, lets the benzoic acid escape. It is soluble in alcohol, but insoluble in water.

BERBERIS, the barberry, a genus of the monogynia order and hexandria class of plants. Calyx, six leaves; petals, six, with two glands at the ungues; stylus, none; the berry has two seeds. There are four species. 1. Berberis cretica, grows to the height of three or four feet. 2. Berberis illicifolia, having leaves like the holm oak. 3. Berberis Sibirica, a small low shrub. 4. Berberis vulgaris, the common barberry which grows wild in hedges in many parts of England. It is cultivated for its fruit which makes a pickle. Its height is from eight to ten feet, with many stalks. The flowers are yellow, and succeeded by an oval fruit, which are at first green, and when ripe become red. There are two or three varieties of this shrub.

BERGAMOT, the name of a fragrant essence extracted from a fruit which is produced by ingrafting a branch of a lemon-tree upon the stock of a bergamot-pear.

BERGESA, a genus of the class and order decandria monogynia. The essential character is, calyx, five-parted; petals, five; berry, subglobular, one-celled, with five seeds.

There is one species, a leafy tree, a native of the East Indies.

BERGIA, a genus of the class and order decandria pentagynia. The essential character is, calyx, five-parted; petals, five; capsule, one, globular, with swellings, five-celled, five-valved, valves resembling petals; seeds many.

There are two species, the B. capensis and glomerata, both natives of the Cape.

BERRY, a round fruit, for the most part soft, and covered with a thin skin, containing seeds in a pulpy substance; but if it is harder, or covered with a thicker skin, it is called pomum, apple.

BERYL, a pellucid gem of a bluish green colour; whence it has been denominated *aqua marina*. It is found in the East Indies, Peru, Siberia, and Tartary, where its crystals are sometimes a foot in length. There are two species of this stone: viz. the oriental or precious beryl, and occidental or schorlous beryl: the former contains silex, alumine, glucine, lime, and oxide of iron; and the latter silex, alumine, lime, and water.

BESANTS, in heraldry, round pieces of gold, without any stamp, frequently borne in coats of arms.

BESLERIA, a genus of the angiospermia order, and didynamia class of plants. There are six species; the principal of which are, 1. Besleria cristata, with stalks growing single and a five-leafed involucrum. The calyx is scarlet; and the corolla yellow. 2. Besleria

lutea, with simple footstalks growing in clusters, and spear-shaped leaves. The flowers are yellow. 3. Besleria melittifolia, with branching footstalks and oval leaves. They are all natives of America, and in this country are stove plants, but are not remarkable for beauty, or any other property.

Beta, the *beet*, a genus of the pentandria digynia class and order of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx has five leaves; there is no corolla; the seeds are kidney-shaped, and situated within the base of the calyx. There are four species. The root of the beet affords a considerable quantity of sugar, and has lately been cultivated for the purpose of extracting it to some extent in Germany. It is likewise said, that if beet roots be dried in the same manner as malt, after the greater part of their juice is pressed out, very good beer may be made from them.

BETEL, or **BETLE**, in botany, a kind of long pepper, found in Malabar, and other parts of the East Indies.

BETONICA, *betony*, a genus of the gymnospermia order, and didynamia class of plants; in the natural method ranking under the 42d order, verticillatæ. The calyx is awned, upper lip of the corolla ascending and flattish; and the tube cylindric. There are seven species; the chief of which are, 1. Betonica orientalis, the oriental betany. 2. Betonica stricta, the greater Danish betany. 3. Betonica incana, the hoary Italian betany, which has a flesh-coloured flower. 4. Betonica officinalis. This is a low plant, and grows in woods and shady places.

BETULA, the alder-tree or birch, a genus of the tetrandria order, and monœcia class of plants, ranking in the natural method under the 50th order, amentaceæ. The male calyx is monophyllous, trifid, and biflorus; the corolla parted into four segments: female calyx monophyllous, trifid and biflorus; seeds winged on both sides. Of the species, which are fifteen, the principal are, 1. Betula alba, or common birch tree. It grows to a considerable height and size, in a good soil and situation. 2. Betula alnus, or the alder tree, is of a straggling growth. It flourishes in swampy places, the roots poison the herbage, and rot the soil. 3. Betula lenta, the Canadian birch, grows to the height of above sixty feet. There are four varieties. 4. Betula nana, the dwarf birch, with roundish leaves, grows naturally in the northern parts of Europe, and on the Alps. 5. Betula nigra, or the black Virginian birch tree, which grows to the height of sixty feet and upwards. The leaves are broad, and the branches are spotted. There are several varieties.

BEVEL, among masons, carpenters, joiners, and bricklayers, a kind of square, one leg whereof is frequently crooked, according to the sweep of an arch or vault. It is moveable on a centre, and so may be set to any angle. The make and use of this instrument are pretty much the same as those of the common square and mitre, except that those are fixed, the first at an angle of ninety degrees, and the second at forty-five; whereas the bevel being moveable, it may in some measure supply the place of both, which it is chiefly intended for, serving to set off or transfer angles, either greater or less than ninety or forty-five degrees.

BEVILE, in heraldry, a thing broken or opening like a carpenter's rule.

BEZOAR, an antidote or medicine intended to expel poison. The *oriental bezoar* is a round stone, varying in size from a pea to a small walnut. It is of an olive or greenish brown colour, and smooth and glossy on the surface. When broken it is found to consist of many coats of stony matter, formed upon a piece of wood, or the seed of a fruit. This drug is of great price, but seems to possess a higher name than real value. It comes from Persia and other parts of the East, and one kind is found in Mexico. Bezoars are supposed to be concretions formed in the stomach or intestines of different animals.

Three bezoars sent to Buonaparte by the king of Persia, were found by Berthollet to be nothing but woody fibre agglomerated.

BIBLE, *the book*, a name given by Christians, by way of eminence, to a collection of the sacred writings.

Various versions of the Sacred Volume are to be met with; some of them are reckoned valuable, in consequence of their antiquity: being made at different periods, by men whose theological sentiments were in some respects different; and rendered into the principal languages, and dialects in use in different parts of the world, it is naturally to be expected that those versions should, in some respect, vary from each other. But after all the laborious research of Biblical critics, it is allowed that even the most important of these differences do in no wise affect the leading object of divine revelation, which is to make known to man the character of God; to acquaint him with the reality of a future state of existence; and the inseparable connection between the nature of his actions here, and the felicity or misery of his state hereafter.

BICEPS, in anatomy, the name of several muscles. See ANATOMY.

BIDENS, a genus of the syngenesia polygamia, æqualis class and order, and in the natural method ranking under the 49th order, compositæ oppositifoliæ. The receptacle is paleaceous; the pappus has erect scabrous awns; and the calyx is imbricated. Of this genus there are fourteen species; but none of them appear to merit notice, except the bidens tripartita, frequently found by the sides of rivulets, ditches, and lakes in England.

BIENNIAL *plants*, are those that have two years' duration, or that are in their prime the first and second summers. They consist both of esculent and flowering plants.

BIGAMY, in law, is where a person marries a second wife, or husband, the first being alive, for which the punishment was formerly death, as in cases of felony; but it is now usually punished with a long imprisonment, or even transportation.

BIGNONIA, the *trumpet-flower*, in botany, a genus of the didynamia angiospermia class. The flower is monopetalous, with a mouth campanulated, and divided into five segments: the fruit is a pod with two cells and two valves, containing several imbricated, compressed, and winged seeds. There are twenty-seven species, mostly trees and shrubs, inhabitants of the hot climates of the East and West Indies, and eminently beautiful.

BILBOES, a punishment at sea, answering to the stocks at land. The offender is laid in irons, or stocks, which are more or less ponderous, according to the quality of the offence of which he is guilty.

BILDGE of a ship, the bottom of her floor, or the breadth of the place the ship rests on when she is aground. Therefore, bildge-water is that which lies on her floor.

BILE, a yellow, bitter juice, separated from the blood in the liver, collected in the porus biliarius and gall-bladder, and thence discharged by the common duct into the duodenum.

BILL, an instrument of iron, edged in the form of a crescent, and adapted to a handle. It is used by plumbers, to perform several parts of their work; by basket-makers, and by gardeners. When short, it is called a hand-bill; and when long a hedge-bill.

Bill, in law, is a declaration in writing, expressing the wrong the complainant had suffered, or some fault committed against some law or statute of the realm; and this bill is sometimes addressed to the lord chancellor, especially for unconscionable wrongs done to the complainant; and sometimes to others having jurisdiction. In criminal cases, when a grand jury upon presentment, or indictment, finds the same to be true, they indorse on it *billa vera*, and thereupon the offender is said to stand indicted.

Bill *of credit*, is that which a merchant or banker gives to a person empowering him to receive money from his correspondents in foreign countries.

Bill *in equity*, is a petition, addressed to the lord chancellor, or exchequer, with which a suit in chancery or the exchequer commences.

Bills *of exchange*. A bill of exchange is an order or request in writing, addressed by one person to another, to pay a certain sum of money on demand, or at a time specified, to a third person, or to his order; or it may be made payable to bearer.

If a bill is made payable to bearer, it is assignable by delivery only; but if it is payable to order, it must be transferred by indorsement and delivery. The person making or drawing the bill is called the *drawer*; the person to whom it is addressed the *drawee*; who, when he has undertaken to pay the amount, is termed the *acceptor*. The person in whose favour the bill is drawn is called the *payee*; but if he appoints some other person to receive the money, he is then termed the *indorser*, and the person so appointed the *indorsee*.

A promissory note, or note of hand, is an engagement in writing, to pay a sum specified at the time therein limited, to a person therein named, or sometimes to his order, or often to the bearer at large: this is also made assignable, and indorsable.

Bill *of entry*, an account of the goods entered at the custom-houses both inwards and outwards.

Bill *of lading*, an acknowledgment signed by the master of a ship, and given to a merchant, &c. containing an account of the goods which the master has received on board from that merchant &c. with a promise to deliver them at an intended place for a certain sum.

Bill *in parliament*, a paper containing propositions offered to the houses, to be passed by them, and then to be presented to the king to pass into an act or law.

Bill *of sale*, is when a person wanting a sum of money delivers goods as a security to the lender, to whom he gives this bill, impowering him to sell the goods in case the sum borrowed is not repaid, with interest, at the appointed time.

Bill *of store*, a licence granted at the custom-house to merchants, by which they have liberty to carry, custom-free, all such stores and provisions as they may have occasion for during their voyage.

Bill *of sufferance*, a licence granted to a merchant, at the custom-house, suffering him to trade from one English port to another without paying custom.

BILLET, in heraldry, a bearing in form of a long square. They are supposed to represent pieces of cloth, of gold, or silver: but Guilim thinks they represent a letter sealed up; and other authors take them for bricks.

BINARY *arithmetic*, a species of arithmetic, invented by Leibnitz, wherein unity, or 1 and 0, are only used. The cipher multiplies every thing by 2, as in common arithmetic Thus, 1 is one; 10, two; 11, three; 100, four, 101, five; 110, six; 111, seven; 1000, eight; 1001, nine; 1010, ten. The design of the inventor appears to have been to expedite the discovery of the properties of numbers, and the construction of tables; but he does n[illegible]mend this method for common use, because of the great number of figures requisite to express a number.

BINDWEED. See Convolvolus.

BINOMIAL, in algebra, a root consisting of two members connected by the sign + or —. Thus $a+b$ and 8—3 are binominals, consisting of the sum and difference of these quantities.

The powers of any binominal are found by a continual multiplication of it by itself. For example, the cube or third power of $a+b$ will be found by multiplication to be $a^3+3a^2b+3ab^2+b^3$; and if the powers of $a-b$ are required, they will be found the same as the preceding, only the terms in which the exponent of b is an odd number will be found negative. Thus, the cube of $a-b$ will be found to be $a^3+3a^2b+3ab^2-b^3$; where the second and fourth terms are negative, the exponent of b being an odd number of these terms. In general, the terms of any power of $a-b$ are positive and negative by turns. See Algebra.

BIPED, an animal with only two legs. Men and birds are bipeds.

The term is used for a genus of reptiles that belong to the lizard family. These have a very long body covered with scales, and the toes of the two little feet are armed with nails.

BIQUADRATIC *power*, in algebra, the fourth power or squared square of a number, as 16 is the biquadratic power of 2; for 2×2 is 4, and 4×4 is equal to 16.

Biquadratic *root of a number*, is the square root of its square root: thus the biquadratic root of 81 is 3; for the square root of 81 is 9, and the square root of 9 is 3.

Biquadratic *equation*, an equation where the unknown quantity of one of the terms has four dimensions.

Any biquadratic equation may be generated

by the multiplication of four simple equations; or it may be formed of two quadratic equations.

BIRCH. See ALDER.

BIRD. See AVES.

BIRD-CATCHING, is the art of taking birds, or wild-fowl, by bird-lime, nets, decoys, &c. The nets used by bird-catchers are about twelve yards long, and two and a half wide; which are spread on the ground at such a distance from each other, that when turned over, they shall coincide. The remaining apparatus consists of lines so fastened to the nets, that the bird-catcher is able by a sudden pull to draw the net over the birds that may alight between the parallel sides. These birds are enticed by others denominated call-birds, which are generally linnets, gold-finches, green-finches, wood-larks, yellow-hammers, tit-larks, and bul-finches. When these birds perceive the approach of the wild birds, the intelligence is announced from cage to cage with the utmost extacy. The note by which they invite them down, has so powerful an ascendancy over the wild birds, that the moment they hear it, they alight on a spot within twenty yards of the bird-catchers.

Birds are also caught in traps, and frequently by nooses of hair. In this way, great numbers of wheatears are annually taken on the various downs of England. Wild ducks are taken in vast numbers every winter on our coasts by means of decoys. Grouse and partridges are taken by means of nets, chiefly by night. Pheasants are sometimes taken by night, by holding flaming sulphur under the trees on which they are observed to perch, the suffocating effluvia of which make them fall senseless.

BIRDS, in heraldry, according to their several kinds, represent either the contemplative or active life. They are the emblems of liberty, expedition, readiness, swiftness, and fear.

BIRDLIME. The best birdlime is made of the middle bark of the holly, boiled seven or eight hours in water, till it is soft and tender; then laid in heaps in pits in the ground and covered with stones, the water being previously drained from it; and in this state left for two or three weeks to ferment, till it is reduced to a kind of mucilage. This being taken from the pit is pounded in a mortar to a paste, washed in river water, and kneaded, till it is freed from extraneous matters. In this state it is left four or five days in earthen vessels, to ferment and purify itself, when it is fit for use.

It may likewise be obtained from the mistletoe, the viburnum lantana, young shoots of elder, and other vegetable substances.

BIRTHWORT. See ARISTOLOCHIA.

BISCUIT, *sea*, is a sort of bread much dried, to make it keep for the service of the sea. It was formerly baked twice, or oftener, and prepared six months before the embarkation. It will keep good a whole year.

BISCUTELLA, *buckler mustard*, or bastard Mithridate mustard: a genus of the tetradynamia siliculosa class and order of plants; and in the natural method ranking under the 39th order, siliquosæ. The silicula is flat, compressed, rounded above, and below two-lobed. There are six species, all natives of France, Italy, Spain, and Germany.

BISECT, to divide into two parts. The rational horizon bisects the globe into two equal parts.

BISERRULA, a genus of the decandria order, and diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ: the legumen is bilocular and flat, and the partition contrary. Of this genus there is only one species known, viz. Biserrula pelecina, an annual plant, with purple flowers; a native of the south of Europe.

BISHOP, a prelate, or person who is set apart for the spiritual government of a diocese. Whether the terms *bishop* and *priest* are used indiscriminately in the New Testament, has long been a point of dispute among the sects into which the Christian world is divided. But whatever difficulties this subject may be attended with, certain it is that the common application is a gross perversion of the term bishop. Indeed the character of a bishop, as delineated in the New Testament, forms a perfect contrast with the character to which the epithet is commonly applied. The bishop of the New Testament is a man who superintends in the church of God from the *purest* and most *disinterested* motives; the very nature of his office implies that he is to teach truth so as to lead his charge to a good life; that he is not to claim to himself power over their souls; that he is to maintain his dignity solely on the ground of the holiness of his office; in one word, the man who holds the office must be blameless, and ready to the performance of every good work.

BISMUTH is a metal of a yellowish or reddish-white colour, little subject to change in the air. It is somewhat harder than lead, and is scarcely, if at all malleable; being easily broken, and even reduced to powder, by the hammer. The internal face, or place of fracture, exhibits large shining plates, disposed in a variety of positions; thin pieces are considerably sonorous. At a temperature of 480° Fahrenheit, it melts, and its surface becomes covered with a greenish-grey, or brown oxide. A stronger heat ignites it, and causes it to burn with a small blue flame; at the same time that a yellowish oxide, known by the name of flowers of bismuth, is driven up. This oxide appears to rise in consequence of the combustion; for it is very fixed, and runs into a greenish glass when exposed to heat alone.

BISSEXTILE, or *leap-year*, a year consisting of 366 days, and happening every fourth year, by the addition of a day in the month of February, which that year consists of 29 days. And this is done to recover the 6 hours which the sun takes up nearly in his course more than the 365 days commonly allowed for it in other years.

BISTOURY, in surgery, an instrument for making incisions, of which there are different sorts; some in the form of a lancet, others straight, and fixed in the handle like a knife, others crooked, with a sharp edge on the inside.

BISTRE. A brown pigment, consisting of the finer parts of wood soot, separated from the grosser by washing. The soot of the beech is said to make the best.

BIT, or **BITTS**, in ship-building, the name of two great timbers usually placed abaft the manger in the ship's loof, through which the cross-piece goes; the use of it is to belay the cable thereto while the ship is at anchor.

BIT, or **BITT**, an essential part of a bridle.

There are many kinds of bits; the most simple is a short rod of iron, made rather wider than the horse's mouth, and furnished with a hook or ring at each end, to which the reins are fastened. The snaffle bit has two cross pieces that rest against the lips or sides of the mouth. In the curb bit the mouth piece has usually an arch in the middle to prevent its resting on the tongue. *Bit* also denotes the iron part of a piercer, auger, or similar instruments. *Bit of a key* is the part containing the wards.

BITTER *principle*. The bitter taste of certain vegetables appears to be owing to the presence of a peculiar substance, differing from every other in its chemical properties. It may be extracted from the wood of quassia, the root of gentian, the leaves of the hop, and several other plants, by infusing them for some time in cold water.

BITUMEN, *See* ASPHALTUM.

BIVALVES, one of the three general classes of shell-fish, comprehending all those, the shells of which are composed of two pieces, joined together by a hinge. The Linnæan genera of bivalve shells are mya, solen, tellina, cardium, mactra, donax, venus, spondylus, chama, arca, astrea, anomia, mytillus, and pinna.

BIXA, the *roucou* or *anotto tree*, a genus of the monogynia order, and polyandria class of plants; and in the natural method ranking under the 37th order, columniferæ. The corolla is ten-petaled; the calyx quinquedented; the capsule hispid and bivalved. Of this genus there is but one species known, viz.

Bixa orellana, a native of America. It rises with an upright stem to the height of eight or ten feet, sending out many branches at the top forming a regular bed, with heart-shaped leaves ending in a point, and having long footstalks.

BLACK, something opake and porous, that imbibes the greatest part of the light that falls on it, reflects little or none, and therefore exhibits no colour. Bodies of a black colour are found more inflammable, because the rays of light falling on them are not reflected outwards, but enter the body and are often reflected and refracted within it, till they are stifled and lost.

Black substances are generally found to be lighter than white, being more porous; clothes dyed of this colour wear out faster than those of any other, from the quantity of vitriol necessary to strike the dye.

BLACK, *chalk*. This mineral has a bluish black colour; a slaty texture; soils the fingers, and is meagre to the touch. It contains about 64 silica, 11 allumina, 11 carbon, with a little iron and water. It is found in primitive mountains, and also sometimes near coal formations. It occurs in Caernarvonshire, and in the island of Isla.

BLACK, *Jack*. The miners distinguish blende, or mock lead, by this name. It is an ore of zinc.

BLACK, *German*, or Frankfort black, is produced from the lees of wine, washed in water, then ground with burned ivory, bones or peach stones. It is chiefly used by copper-plate printers for working off their engravings.

BLACK, *ivory*, a substance made from burned

in water, and made into troches for the use of painters, Jewelers, &c. In order to be good it must be tender, friable, and thoroughly ground.

BLACK, *lamp*, the finest kind of this article is produced by collecting the smoke from a lamp with a long wick, which supplies more oil than can be perfectly consumed, or by suffering the flame to play against a metaline cover, which impedes the combustion, not only by conducting off part of the heat, but by obstructing the current of air. Lampblack, however, is prepared in a much cheaper way, for the demands of trade. The dregs which remain after the eliquation of pitch, or else small pieces of fir wood, are burned in furnaces of a peculiar construction, the smoke of which is made to pass through a long horizontal flue, terminating in a close boarded chamber. The roof of this chamber is made of coarse cloth, through which the current of air escapes, while the soot remains behind.

BLACK, *lead*. *See* PLUMBAGO.

BLACKBURNIA, a genus of the tetrandria monogynia class and order. The essential character is, calyx four toothed; pet. 4; anther heart-shaped; germ. conic; stigma simple; berry one-seeded. There is but one species, a native of Norfolk-island.

BLADDER, a thin membranous substance found in several parts of an animal, serving as a receptacle of some juice, or of some liquid excrement, as the urinary bladder, gall bladder &c.

BLADHIA, a genus of the class and order pentandria monogynia. The essential character is, corolla wheel shaped, deciduous; berry containing one seed. There are three species, natives of Japan.

BLÆRIA, in botany, a genus of the tetrandria monogynia class and order of plants. Its characters are; calyx quadripartite, corolla quadrifid, stamina inserted in the receptacle; the fruit a capsule, with four cells, containing many seeds. There are six species.

BLAIN, among farriers, a distemper incident to beasts; being a certain bladder growing on the root of the tongue, against the windpipe, which swells to such a degree as to stop the breath. To cure it, cast the beast, take forth his tongue, and then slitting the bladder, wash it gently with vinegar and a little salt.

BLAKEA, in botany; a genus of the cla and order dodecandria monogynia: with calyx composed of six leaves below, and entire above; six petals, and a six-celled polyspermous capsule. There are two species, very beautiful shrubs, natives of America.

BLANCHING *of copper* is done various ways, so as to make it resemble silver. If it be done for sale, it is felony by 8 and 9 William III. ch. xxvi.

BLANCHING, in coinage, the operation performed on the planchets or pieces of silver, to give them the requisite lustre and brightness. They also blanch pieces of plate, when they would have them continue white, or have only some parts of them burnished.

Blanching, as it is now practised, is performed by heating the pieces on a kind of peel with a wood-fire, in the manner of a reverberatory: so that the flame passes over the peel. The pieces being sufficiently heated and

common salt, and tartar of Montpelier. When they have been well drained of this water in a copper sieve, they throw sand and fresh water over them; and when dry, they are well rubbed with towels.

Among gardeners, blanching signifies an operation by which certain sallads, roots, &c, are rendered whiter than they would otherwise be, which is effected by covering them, as they grow, with earth.

BLASIA, in botany, a genus of the cryptogamia hepaticæ class and order. Male solitary; imbedded in the frond: female no calyx; capsule imbedded in the frond, oblique, one-celled, with a tubular mouth: seeds numerous. There is one species, a native of England.

BLASPHEMY, a term signifying an indignity, or more properly an injury offered to the Supreme Being, by denying what is his due, or by attributing to the creature what is due only to the Creator. Writers on the subject of blasphemy, seem to have overlooked a most important point, viz. that the denial of the sacred writings to be a transcript of the divine mind amounts to blasphemy. Among the Jews blasphemy was punished by stoning the offender to death; this, like all the other parts of the conduct of that remarkable people, had, doubtless, a symbolical signification; and, perhaps, was intended to teach us that the most effectual method of dealing with blasphemers is, to bring to bear upon their ignorant and foolish objections the doctrines of HIM who is emphatically styled, "*the Stone which the builders rejected.*"

BLAST, in a general sense, denotes any violent explosion of air, whether occasioned by gunpowder, or by the action of a pair of bellows

BLAST, a disease in grain and trees, called also a blight: by some supposed to be owing to cold; and by others to the want of a due supply of sap; some attribute it to ascending fumes from the earth, others to sharp winds and frosts succeeding rain.

But what is termed the blight is frequently nothing more than a debility or distemper in the trees themselves.

BLATTA, a genus of hymenopterous insects, well known in England under the names of cockroaches and black beetles. The blatta most abundant in England, came from America or the East. The best method of clearing them is by a tame hedgehog. All the known species of this insect, whether in the larva, pupa, or perfect winged state secrete themselves in the day, and wander about in the night. Naturalists have enumerated no less than 43 species.

BLAZONING, in heraldry, the art of decyphering coats of arms. In blazoning always begin with the field, and next proceed to the charge; and if many things are borne, begin with that which lies immediately on the field. Such terms for the colours must be used as are suited to the rank of the bearer, and all superfluous expressions must be avoided.

BLEACHING, the art of freeing those articles of manufacture which have vegetable substances for their raw material, from the colouring matter with which such substances are naturally combined. Although the art of bleaching must have been known to the world at a very early period, yet it was not till towards the close of the 18th century that it made rapid progress even in Europe. Till about that time the old, tedious process of bleaching remained in use, which has now, almost universally, given way to the new method of bleaching by means of the oxymuriatic acid. This process, which is attended with immense advantage to the manufacturer, was the discovery of the celebrated Scheele, but the application of it to the art of Bleaching justly belongs to Mr. Berthollet. Various inconveniences were found to attend the process of bleaching cloth by subjecting it to the action of the oxygenated muriatic acid, notwithstanding its great superiority to the old method. These led to the addition of an alkali to the acid; but the use of potash or pearlash was attended with a great additional expense, besides having the effect of weakening the power of the acid. Hence it became an object of importance to the manufacturers of this country to substitute a cheaper substance which should have the same effect. Lime was tried at first in an imperfect manner, but at length with such improvements that it is now always used.

An improvement however of still greater importance has been made by Mr. Tennant of Glasgow, for which he obtained a patent. This improvement consists in combining chlorine with pulverulent lime. By this process a bleaching powder is produced, known in commerce by the name of oxymuriate of lime, which is portable to any distance at a small expense. For use, this powder is diffused in water by agitation; the insoluble matter contained in the lime is allowed to subside until the liquor becomes transparent. When drawn off for use it is further diluted with water, before the goods are immersed in it that are to be whitened. This chloride, well prepared and properly applied will not injure the most delicate muslins. It is also used with great effect in the manufacture of paper; in cleaning old books and prints: and in whitening wax. Silk and woollen stuffs being animal substances are bleached by a process peculiar to themselves thus briefly described by Dr. Ure.

"The colouring principle of silk is undoubtedly resinous. Hence Mr. Baume proposed the following process as the best mode of bleaching it. On six pounds of yellow raw silk, disposed in an earthern pot, 43 pounds of alcohol, sp. gr. 0.867 mixed with 12 oz. muriatic acid. sp. gr. 1.100 are to be poured.

After a day's digestion, the liquid passes from a fine green colour to a dusky brown. The silk is then to be drained, and washed with alcohol. A second infusion with the above acidulated alcohol is then made, for four or six days, after which the silk is drained and washed with alcohol. The spirit may be recovered by saturating the mingled acid with alkali or lime, and distilling. Mr. Baume says, that silk may thus be made to rival or surpass in whiteness and lustre, the finest specimens from Nankin. But the ordinary method of bleaching silk is the following: —The silk, being still raw, is put into a bag of thin linen, and thrown into a vessel of boiling river water, in which has been dissolved good Genoa or Toulon soap.

After the silk has boiled two or three hours in that water, the bag being frequently turned,

it is taken out to be beaten, and is then washed in cold water. When it has been thus thoroughly washed and beaten, they wring it slightly, and put it, for the second time, into the boiling vessel, filled with cold water, mixed with soap and a little indigo; which gives it that bluish cast commonly observed in white silk.

When the silk is taken out of this second water, they wring it hard with a wooden peg, to press out all the water and soap; after which they shake it, to untwist it, and separate the threads. Then they suspend it in a kind of stove constructed for that purpose, where they burn sulphur; the vapour of which gives the last degree of whiteness to the silk.

The method of bleaching woollen stuffs.—There are three ways of doing this. The first is with water and soap; the second with the vapour of sulphur; and the third with chalk, indigo, and the vapour of sulphur.

Bleaching with soap and water.—After the stuffs are taken out of the fuller's mill, they are put into soap and water, a little warm, in which they are again worked by the strength of the arms over a wooden bench: this finishes giving them the whitening which the fuller's mill had only begun. When they have been sufficiently worked with the hands, they are washed in clear water and put to dry.

This method of bleaching woollen stuffs is called the natural method.

Bleaching with sulphur.—They begin with washing and cleansing the stuffs thoroughly in river water; then they put them to dry upon poles or perches. When they are half dry, they stretch them out in a very close stove, in which they burn sulphur; the vapour of which diffusing itself, adheres by degrees to the whole stuff, and gives it a fine whitening: this is commonly called Bleaching by the flower, or bleaching of Paris, because they use this method in that city more than any where else.

BLECHNUM, in botany, a genus of plants of the class of the cryptogamia filices; the fructifications of which are disposed in two parallel lines, approaching to the rib of the frond. There are six species, all foreign plants.

BLENNIUS, the BLENNY, a genus of fishes belonging to the order of jugulares; the characters of which are: the head slants or declines to one side, there are six rays in the membrane of the gills; the body tapers towards the tail; the belly fins have only two blunt bones: and the tail fin is distinct.

BLIGHT. See BLAST.

BLINDNESS, signifies a total privation of sight, arising from some obstruction of the organs of sight, or from a total deprivation of them.

It is a very remarkable circumstance that persons who are either born blind, or who lose their sight at an early period, generally possess what amounts to a compensation for the loss of sight. Numerous proofs of this are on record: the case of Professor Saunderson is well know; and the names of Blacklock, Milton, Moyes, and others bear evidence to the fact. This is not the place to enter on a discussion of the subject; but we cannot help suggesting the idea that the cases above mentioned appear to furnish a powerful argument against the correctness of the system of some modern zoologists, who affirm that mind is no more than an effect of the organization of matter. Have we not here a satisfactory proof of the existence of an interior sight, after the organ, by disease, has ceased to be of service to it.

Various plans have been devised for the instruction of the blind, some of which have proved highly useful: the *Essay on the Education of the Blind* by Mr. Haüy does great honour to the author; it contains a detail of a great variety of expedients by which the blind may be successfully instructed in many of the mechanic arts, as well as in music, arithmetic, geography, &c., and may even be taught to read, write, and print.

BLINDS, in the art of war, a sort of defence made of oziers, or branches interwoven and laid across between two rows of stakes, used at the heads of trenches, to shelter the workmen, and prevent their being overlooked by the enemy.

BLISTER, in medicine, a thin bladder containing a watery humour, whether occasioned by burns, and the like accidents, or by vesicatories laid on different parts of the body for that purpose.

BLITUM, the blite, or *strawberry spinach*, a genus of the digynia order and monandria class of plants, and of the 12th natural holoraceæ. There are 4 species, 1. Blitum capitatum, which is a native of Spain and Portugal. It is an annual plant. The fruit is full of a purple juice, but not eatable, 2. Blitum Tartaricum, is a native of Tartary. It grows nearly three feet in height: but the flowers and fruit are smaller than those of the capitatum. 3. Blitum virgatum is a native of France and Italy. It is smaller than either of the preceding. 4. Blitum chenopodiodes is a low plant and a native of Tartary. All these species are propagated by seeds.

BLOCKS, on ship-board, is the usual name for what we call pulleys at land. They are thick pieces of wood, some with three, four, or five shivers in them, through which all the running ropes run. Blocks, whether single or double, are distinguished and called by the names of the ropes they carry, and the uses they serve for.

Blocks now used in the navy are made in the Portsmouth yard, by means of machinery, which has lately been erected for the purpose, and which performs the several operations from the rough timber to the perfect block in the completest manner possible.

BLOCKADE, in the art of war, the blocking up a place by posting troops at all the avenues leading to it, to keep supplies of men and provisions from getting into it; and by these means proposing to starve it out without making any regular attacks.

BLOOD, SANGUIS, a red liquor circulating through the arteries, veins, and other vessels of animal bodies; and serving for the support of life, and nourishment of all their parts. See ANATOMY, and PHYSIOLOGY.

BLOW-PIPE, a hollow tube, used by chemists, enamellers, glass-makers, jewellers, &c. It is a wind instrument for the purpose of increasing the heat of a candle or lamp.

Great and important improvements have recently been made in the construction of the blow-pipe. Instead of the simple tube of brass

through which the breath of the operator was impelled, we have now the self-acting blow-pipe, variously constructed; but without enumerating the varieties of this instrument it may be sufficient to state that, for the general purposes of the mineralogist, nothing can exceed the powers of that which is sold by the philosophical instrument makers, under the name of the oxy-hydrogen blow-pipe, charged with one part of oxygen, and two of hydrogen, by means of a condensing syringe; and which is capable of obtaining the highest temperatures; and of fusing the most refractory substances submitted to its action.

BLOWING *machine*, an engine for forcing air with great velocity into a furnace to increase the combustion; blowing-engines are now used in all the practical operations of metallurgy.

BLOWING *of glass*, one of the methods of forming the divers kinds of works in the glass manufacture.

It is performed by dipping the point of an iron blowing-pipe in the melted glass, and blowing through it with the mouth.

BLUE, otherwise called azure, is one of the primitive colours of the rays of light.

Blue, *painter's*, is made different according to the different kinds of painting.

In limning, fresco, and miniature, they use indifferently ultra-marine, blue ashes, and smalt: these are their natural blues, excepting the last, which is partly natural and partly artificial.

BLUING *of iron*, is a method of beautifying that metal, which is thus effected. When the surface is perfectly clean, the metal is subjected to the heat of a clear charcoal fire; and, as the heat increases, it becomes first of a light, then of a deep straw colour, and lastly of a fine blue.

BOA, a genus of serpents. See Serpent.

BOAR. See Sus.

BOARD, among seamen, signifies to go into the ship. Board and board, is when two ships come so near as to touch one another, or when they lie side by side. To make a board, is to turn to windward. To board it up, is to beat it up sometimes upon one tack, and sometimes upon another. The weather board is that side of the ship which is to windward.

BOAT, is a small open vessel worked by oars or sails. The construction and names of boats are different, according to the purposes for which they are intended. The boats or wherries plying on the Thames about London are either scullers, wrought by a single person with oars; or boats, wrought by two persons each with an oar.

Boat, *life*, a boat invented by Mr. Henry Greathead, of South Shields, for the purpose of preserving the lives of shipwrecked persons.

For this invention, Mr. Greathead received a gold medal and fifty guineas from the Society of Arts, in 1802; and a Parliamentary reward of 1200 pounds, besides further remuneration from the Trinity House, and from Lloyd's Coffee House. The boat is thirty feet in length, and ten in breadth, and its depth three feet. Captain Manby, of the Royal Navy, has suggested a plan by which, at a trifling expense, any boat may be easily converted into a life boat. This is done by connecting with the boat a number of empty casks, which give it such a degree of buoyancy, that when filled with water, it may be rowed with ease, and perform any service required.

BOATSWAIN, a ship-officer, to whom is committed the charge of all the tacklings, sails and rigging, ropes, cables, anchors, flags, pendants, &c. He is also to take care of the long-boat and its furniture, and to steer her either by himself or his mate. He calls out the several gangs and companies aboard, to the due execution of their watches, works, spells, &c.

BOBBIN, a small piece of wood turned in the form of a cylinder, with a little border jutting out at each end, bored through to receive a small iron pivot.

BOCCONIA, in botany, a genus of the monogynia order, and dodecandria class of plants, in the natural method belonging to the 27th order, rhœadeæ. The only species is the bocconia frutescens, which is a native of America and the West Indies. It grows to the height of twelve feet, and the trunk is covered with a white bark. At the top it divides into several branches on which the leaves are situated alternately. The plant abounds with an acrid juice, used by the inhabitants to remove warts and spots from the eyes.

BODY, in physics, an extended solid substance, of itself utterly passive and inactive, indifferent either to motion or rest; but capable of any sort of motion, and all figures and forms.

Body, in geometry. The regular bodies, or those which have all their angles and sides similar and equal, are five, viz. tetrahedron, octahedron, dodecahedron, icosahedron, and the cube. See Geometry.

Bodies, *descent of*, See Mechanics.

BOEHMERIA, a genus of the monœcia tetrandria class and order.

There are 5 species, natives of America and the West Indies.

BOERHAAVIA, a genus of the monogynia order, and monandria class of plants. There are 7 species, all natives of the Indies.

BOILING or *ebullition*, is the agitation of a fluid body, arising from the application of heat. All fluidity is the effect of a quantity of caloric, or the matter of heat, absorbed by a body in passing from a solid to a fluid state, and boiling is the act of a body from a fluid state, to that of vapour, by a further absorption of the caloric. If the heat is applied to the bottom of the vessel, after the whole liquid has acquired a certain temperature, those particles next the bottom become elastic, and ascend as they are formed through the liquid like air-bubbles, and throw the whole into violent agitation. The liquid is then said to boil. Every liquid has a fixed point, at which boiling commences, and this is called the boiling point. Thus water begins to boil when heated to 212 degrees. After a liquid has begun to boil, it will not become hotter, however much the fire may be increased.

It was observed, however, by Dr. Hooke, that a stronger heat makes all liquids boil more rapidly, though it does not increase their temperature.

BOLE. A massive mineral, having a perfectly conchoidal fracture a glimmering internal lustre, and a shining streak. Its colours are yellow-red, and brownish-black, whence it is called mountain soap. It is trans-

lucent or opaque. Soft, so as to be easily cut, and to yield to the nail. It adheres to the tongue, has a greasy feel, and falls to pieces in water. Sp. grav. 1. 4 to 2. It may be polished. If it be immersed in water after it is dried, it falls asunder with a crackling noise. It occurs in wacke and basalt, in Silesia, Hessia, and Sienna in Italy, and also in the cliffs of the Giant's Causeway in Ireland.

BOLETUS, in botany, so called from its globular form, characterised by Linnæus as a horizontal fungus; porous, with lobes underneath. In the fourteenth edition of the "Systema Naturæ, only twenty-one species are recited, eleven of which are parasitical and stemless, the rest are stipitated. From B. igniarius is prepared the amadou, commonly used on the Continent for tinder, to receive the spark struck from the steel by the flint, and the agaric for stopping hæmorrhages in amputations, &c.

BOLOGNIAN *Stone.* Lemery reports, than an Italian shoemaker, named Vincenzo Casciarolo, first discovered the phosphoric property of the Bolognian stone. It is the ponderous spar, or native sulphate of barytes.

If it be first heated to ignition, then finely powdered, and made into a paste with mucilage; and this paste divided into pieces a quarter of an inch thick, and dried in a moderate heat, be exposed to the heat of a wind furnace, by placing them loose in the midst of the charcoal; a pyrophorus will be obtained, which, after a few minutes' exposure to the sun's rays, will give light enough in the dark to render the figures on the dial-plate of a watch visible.

BOMB, in military affairs, a globe or shell of cast iron, having a vent to receive a wooden fuse. The shell being filled with powder the fuse is fastened with a cement within an inch of the head. The tube is filled with a combustible matter, which burns when the bomb is fired off, and at last communicating with the gunpowder, the bomb bursts with great violence.

BOMBARDMENT, the act of assaulting a fortified place, by throwing shells into it to destroy the houses, magazines, &c. The mortars for firing bombs are usually fixed at an elevation of forty-five degrees, by which means the shell describes a curve called the military projectile; but the elevation must necessarily vary according to distance and other circumstances.

BOMBAX, in botany, the silk cotton-tree; a genus of the polyandria order, and monodelphia class of plants; and in the natural method ranking under the 37th order, columniferæ. The species are:

1. Bombax ceiba, with a prickly stalk.

2. Bombax heptaphyllum, with leaves cut into seven parts. The cotton is of a fine purple colour, but the size of the tree is not particularly mentioned by botanical writers.

3 Bombax pentandrum, with a smooth stalk. This and the ceiba grow naturally in both the Indies, where they arrive at a great magnitude being some of the largest trees in those parts. Bosman says, he has seen in Guinea trees of this kind so widely diffused, that 20,000 armed men might stand under the branches of one. They generally grow with straight stems.

BOMB *ketch*, a small vessel built and strengthened with large beams for the use of mortars at sea.

A bomb ketch is generally from 60 to 70 feet long, and draws eight or nine feet of water.

BOMBIC *acid*, in chemistry, an acid found in a cavity near the anus of the silk-worm. It is of a yellowish colour.

BOMBAX. See PHALÆNA.

BOND. A bond is a deed whereby the person bound, binds himself, his heirs, executors, and administrators, to pay a certain sum of money, or do some other act against a certain day.

If the condition of a bond is impossible at the time of making it, if it is to do a thing contrary to law, the obligation is void. The bond of a feme converte is void, as is that of an infant. If a person is in confinement, and, during such restraint, enters into a bond to a person who causes the restraint, the same may be avoided for duress of imprisonment.

A bond, *post obit*, is one that becomes payable after the death of some person therein specified.

BONE, is the most solid part of animal substances; it is white, hard, brittle and forms the principal support of the whole fabric. The bones of men and quadrupeds owe their firmness and solidity to a considerable portion of the phosphate of lime which they contain. These when rasped small, and boiled in water afford gelatinous matter, and a portion of fat, or oil which occupied their interstices. Bones are of extensive use in the arts. In their natural state, or dyed of various colours, they are made into handles of knives and forks, and numerous articles of turnery.

BONES, fossile or petrified, are those found in the earth, frequently at great depths in all strata, even in the bodies of stones and rocks. Some of these bones are of a huge size, usually supposed to be the bones of giants, but more truly of elephants or hippopotami, others smaller, as the vertebræ, teeth, and the like.

BONNET, in fortification, a small work, consisting of two faces, having only a parapet with two rows of palisadoes, of about ten or twelve feet distance. It is generally raised before the salient angle of the counterscarp, and has a communication with the covered way by a trench cut through the glacis, and palisadoes on each side.

BOOK, is a general name given to a work compesed for the purpose of comunicating the knowledge of its author on the subject or subjects on which it treats. The etymology of the word book indicates that books were originally written on vegetable substances: Such as the bark of trees, the leaves of plants, or on tablets of wood, which practice, indeed, is still continued in those nations that have made but little progress in refinement. The works of Hesiod were written on tables of lead, and the laws of Solon were cut on planks of wood.

There is at present in France a book that is neither written nor printed, and bears the following title. *Liber Passionis Domini Nostri Jesu Christi cum Figuris et Characteribus nulla Materia compositis.*

This work consists of the finest vellum: the letters are all cut out of each folio; and, being interleaved with blue paper, the reading is as distinct as any printing.

BOOK *binding*, is the art of sewing together the sheets of a book, and securing them with a back and side boards. The leaves being folded in the order of the signatures, are beaten on a stone with a hammer to make them smooth. they are then put into a press and sewed on

bands, after which the backs are glued and the bands opened and scraped for the better fixing the pasteboards; the back is turned with a hammer, and the book fixed in a press between two boards, in order to make a groove for the pasteboard; holes are then made for fixing them to the book, which is pressed a third time. Then the book is put into the cutting press betwixt two boards, one lying even with the press for the knife to run upon, the other above for the knife to run against; after which the pasteboards are squared. The next operation is the sprinkling the leaves, which is done by dipping a brush in vermilion and sap green, holding the brush in one hand and spreading the hair with the other. The covers being moistened in water are cut to the size of the book, then smeared with paste and afterwards stretched over the pasteboard on the outside, and doubled within, after having taken off the four angles and indented and platted the cover at the head-band: which done the book is covered and bound between two bands and set to dry. It is afterwards washed with paste and water, and then sprinkled with a brush; unless it is to be marbled when the spots are made larger by the addition of vitriol. After this the book is glazed with the white of an egg and lastly polished with a hot iron. The letters and ornaments are made with gilding tools or brass cylinders rolled along by a handle. To apply the gold the leather is glazed with a liquor made of whites of eggs diluted with water, and, when nearly dry, the gold leaf is laid on and applied with tools heated first in a charcoal fire.

BOOK *keeping*, an art teaching how to record and dispose the accounts of business, so that the true state of every part and of the whole may be distinctly known.

Merchants' books are kept either by single, or double entry. Those who keep them by the former method have occasion for only a journal or day-book, and a ledger or post-book; the former to enter all the articles as they occur in the course of business, and the other to draw out the accounts of all debtors and creditors on the journal. This method is only proper for traders who have but very little business; but wholesale dealers, who keep their books according to the double entry, or Italian method, require several other books.

The most considerable books according to the method of double entry, are, the waste-book, the journal, and the ledger; but besides these three, which are absolutely necessary, there are several others, to the number of thirteen, or even more, called subservient or auxiliary books, which are used in proportion to the business a man has or to the nature of the business a man carries on. These books are the cash-book, the debt-book, the book of numeros, the book of invoices, the book of accounts current, the book of commissions, orders, or advices, &c.

The *waste-book* is a register, containing an inventory of a merchant's effects and debts, with a distinct record of all his dealings.

The waste-book opens with the inventory, which consists of two parts; first, the effects, that is, the money a merchant has by him, the goods in hand, his part of ships, houses, farms, &c. with the debts due to him; the second part of the inventory is the debts due by him: the difference between which, and the effects, is what is called neat stock.

After the inventory is fairly related in the waste-book, the transactions of trade come next to be entered down; which is a daily task to be performed as they occur. The narrative ought to exhibit transactions with all the circumstances necessary to be known, and no more. It should contain the names of persons with whom the merchant deals upon trust, the conditions of bargains, the terms of payment, the quantity, quality, and prices of goods, with every thing that serves to make the record distinct, and nothing else. The waste-book, if no subsidiary books are kept, should contain a record of all the merchant's transactions and dealings in a way of trade; and that not only of such as are properly mercantile, but of every occurrence that affects his stock, so as to impair or increase it.

The *journal*, or *day-book*, is the book wherein the transactions recorded in the waste-book are prepared to be carried to the ledger, by having their proper debtors and creditors ascertained and pointed out: whence it may be observed, that the great design of it is to prevent errors in the ledger. After the ledger is filled up, the journal facilitates the work required in revising and correcting it; for first the waste-book and journal are compared, and then the journal and ledger; whereas to revise the ledger immediately from the waste book, would be a matter of no less difficulty, than to form it without the help of a journal: lastly, the journal is designed as a fair record of a merchant's business; for neither of the other two books can serve this purpose; not the ledger, by reason of the order that obtains in it, and also on account of its brevity, being little more than a large index: nor can the waste-book answer this design, as it can neither be fair nor uniform, nor very accurate, being commonly written by different hands, and in time of business.

In the journal, persons and things are charged debtors to other persons and things as creditors; and in this it agrees with the ledger, where the same style is used, but differs from it as to forms and order; so that it agrees with the waste-book in those very things where it differs from the ledger.

It may be observed, that every case or example of the waste-book, when entered into the journal, is called a journal post, or entrance.

Accounts in the ledger consist of two parts, which in their own nature are directly opposed to, and the reverse of one another, and are therefore set fronting one another, and on opposite sides of the same folio.

The two parts in any case in the waste-book, when posted to the journal, are denominated the one the debtor, the other the creditor of that post; and when carried from thence to the ledger, the debtor, or debtor part, is entered upon the left side (hence called the debtor side) of its own account, where it is charged debtor to the creditor part: again, the creditor, or creditor part, is posted to the right side, or creditor side of its account, and made creditor by the debtor part. Hence Italian book-keeping is said to be a method of keeping accounts by double entry, because every single case of the waste-book requires at least

two entrances in the ledger, *viz.* one for the debtor, and another for the creditor.

Of the ledger. The ledger is the principal book wherein all the several articles of each particular account, that lie scattered in other books, according to their dates, are collected, and placed together in spaces allotted for them, in such a manner, that the opposite parts of every account are directly set fronting one another, on opposite sides of the same folio.

The folios are divided into spaces, on the head of which are written the titles of the accounts, marked Dr. on the left hand page, and Cr. on the right: below which stand the articles, with the word *To* prefixed on the Dr. side, and the word *By* on the Cr. side; and on the margin are recorded the dates of the articles, in two small columns. The money columns are the same as in other books: before them stand the folio column, which contains figures, directing to the folio where the corresponding ledger-entrance of each article is made; for every thing is twice entered in the ledger. Besides these columns, there must be kept in all accounts, where number, measure, weight, or distinction of coins is considered, inner columns to insert the quantity; and for the ready finding any account in the ledger, it has an alphabet or index, wherein are written the titles of all accounts, with the number of the folio where they stand.

Rules for filling the ledger from the journal. 1. Turn to the index, and see whether the Dr. of the journal post, to be transported, is written there: if not, insert it under its proper letter, with the number of the folio to which it is to be carried.

2. Having distinguished the Dr. and the Cr. sides, complete the entry in one line, carrying the sum to the money columns; and inserting the quantity, if it is an account of goods, &c. in the inner columns, and the referring figure in the folio column.

3. Turn next to the creditor of the journal-post, and so proceed in the same manner with it, both in the index and ledger; with this difference only, that the entry is to be made on the Cr. side, and the word By prefixed to it.

4. The post being thus entered in the ledger, return to the journal, and on the margin mark the folios of accounts, with the folios of the Dr. above, and the Cr. below, and a small line between them, thus $\frac{1}{2}$. These marginal numbers of the journal are a kind of index to the ledger.

5. In opening the accounts in the ledger, follow the order of the journal; beginning with the first journal-post, allow the first space for the Dr. the next for the Cr. the third for the Dr. of the following post, and so on till the whole journal be transported.

Cash Book. This is the most important of the auxiliary books. It is so called, because it contains, in debtor and creditor, all the cash that comes in, and goes out of a merchant's stock; the receipts on the debtor side; the person of whom it was received, on what, and on whose account.

Book of debts or payments, is a book in which is written down the day on which all sums become due, either to be received or paid, by bills of exchange, notes of hand, merchandizes bought or sold, or otherwise Other auxiliary books besides these are kept according to the nature and extent of the concern.

BOOKSELLER, one who trades in books, whether he prints them himself, or gives them to be printed by orders.

Booksellers are in many places ranked among the members of universities, and entitled to the privilege of students, as at Tubingen, Saltsburg, and Paris, where they have always been distinguished from the vulgar and mechanical traders, and exempted from divers taxes and impositions laid upon other companies.

BOOM, in the sea-language, a long piece of timber with which the clue of the studding-sail is spread out; and sometimes the boom is used to spread or boom out the clew of the mainmast.

The different kinds of booms have different names according to the purposes for which they are intended.

BOOM denotes also a cable stretched athwart the mouth of a river or harbour; with yards, top-masts, battling, or spars of wood lashed to it, to prevent an enemy's coming in.

BOOTES, a constellation of the northern hemisphere, consisting of 23 stars according to Ptolemy's catalogue, of 28 in Tycho's, of 34 in Bayer's, of 52 in Hevelius's, and of 45 in Mr. Flamsteed's catalogue.

BORACIC *acid*. See ACID (BORACIC.) This acid has been found native on the edge of hot springs, near Sapo in the territory of Florence; also attached to specimens from the Lipari Islands, and from Monte Rotondo, to the west of Sienna. It is in small early scales, and also massive, fusing at the flame of a candle into a glassy globule. It consists, by Klaproth's analysis, of 86 boracic acid, 11 ferruginous sulphate of manganese, and 3 sulphate of lime.

BORAGO, in botany, a genus of the pentandria monogynia class and order, the flower of which consists of a single petal of the length of the cup, and is divided into five segments: there is no pericarpium, but the cup grows larger and is inflated, and contains four roundish seeds. There are five species.

BORASSUS, a genus of plants, of the dioecia hexandria class and order. The male flower is called ampana, and the female catimpana, on account of their different appearance. There is only one species, a native of Ceylon.

BORAX, or *sub-borate of soda*, is a substance dug out of wells in Thibet, and imported into England from India. It is in whitish crystals, has an alkaline taste, and turns vegetable blues green. It is soluble in water, twenty times its weight of water; it is much used as a flux in soldering metals, but is little used in medicine. Its specific gravity is 1.740. According to Bergman it contains 39 parts of boracic acid, 17 of soda, and 44 of water.

BORDURE, in heraldry, a cutting off from within the escutcheon all round it about $\frac{1}{5}$th of the field, serving as a difference in a coat of arms, to distinguish families of the same name, or persons bearing the same coat.

BORE, among engineers, denotes the diameter of the barrel of a gun or cannon, or rather its whole cavity.

BORE, *square*, among mechanics, a square piece of well tempered steel, fitted into a

handle, serving to widen holes, and make them perfectly round.

BORING, is the method of piercing the earth in search of minerals, &c. The scooping irons made use of for this purpose are drawn back at proper times and the samples of earth and mineral matters they bring up are examined to know whether it is worth while to open a mine in the place.

BOROUGH, or BURGH, a corporation or town which is not a city. The word in its original signification meant a company consisting of ten families, which were bound together as each other's pledge.

The name is now particularly appropriated to such towns or villages as send burgesses or representatives to parliament.

BOROUGHS, *Royal*, in Scotland, are corporations made for the advantage of trade, by charters granted by several of their kings, having the privilege of sending commissioners to represent them in parliament, besides other peculiar immunities. They form a body of themselves, and send commissioners each to an annual convention at Edinburgh, to consult the benefit of trade and their general interest.

BOROUGH-*English*, a customary descent of lands or tenements, in certain places, by which they descend to the youngest instead of the eldest son; or, if the owner has no issue, to the younger instead of the elder brother.

BOS, in zoology, *the ox*, a genus of quadrupeds of the order pecora. The generic character is, horns concave, turned outwards, lunated, smooth; front teeth, eight in the lower jaw, canine teeth, none.

1st. The bison, from which the several races of common cattle have been gradually derived, is found wild in many countries; inhabiting woody regions, and arriving at a size far larger than that of the domestic or cultivated animal. In its native state, the bison is distinguished, not only by his size, but by the depth and shagginess of his hair; which, about the head, neck, and shoulders, is sometimes of such length as almost to touch the ground. His colour is a blackish brown, his eyes large and fierce, his limbs extremely strong, and his whole aspect savage and gloomy.

2nd. Common ox. This is, in reality, the bison reduced to a domestic state; in which it runs into as many varieties as the sheep.

The British breed of horned cattle has been so much improved by a foreign mixture, that it is difficult to point out the original kind.

3d. Indian ox. This variety is found in many parts of India, also in the Indian and African islands, and particularly in Madagascar. It is of a reddish colour, of a very large size, and is distinguished by a very large protuberance above the shoulders.

4th Zebu. This variety resembles the preceding, but is extremely small. In colour it differs like the common cattle; being either grey, brown, white, &c. or variously spotted.

5th. Loose-horned ox. This is said to be found in Abyssinia and Madagascar, and to be distinguished by pendulous ears, and horns attached only to the skin, so as to hang down on each side.

6. Boury. Of the size of a camel, and of a snowy-whiteness, with a protuberance on the back. Native of Madagascar, and some other islands, called by the name of Boury.

7. Tinian ox. Of a white colour, with black ears. Inhabits the island of Tinian.

II. Bos *Arnee*, (ox with upright lunated horns, flat and wrinkled on their upper surface.)

This is an Indian species, remarkable for its vast horns, which are sometimes seen in museums.

III. Bos *Babylus*, or buffalo ox, with horns lying backwards, turning inwards, and flat on the fore part.

In its general appearance, the buffalo is nearly allied to the common ox. It differs, however, in the form of its horns, and in some parts of its internal structure, and is rather superior in size to the common ox. The general or prevailing colour is blackish, except the hair on the top of the forehead, and that at the tip of the tail, which is of a yellowish white.

As the buffalo in his domesticated state is larger and stronger than the ox, he is employed with advantage in different kinds of labour. Buffaloes are made to draw heavy loads, and are commonly directed and restrained by means of a ring passed through the nose.

The buffalo, like other animals of this genus, admits of varieties. Of these the most remarkable is the small naked Indian buffalo of Mr. Pennant.

IV. Bos *Moschatus*, or musk ox, having very long pendant hair, and horns bending inwards and downwards, and outwards at the tips.

It is a native of North America, where it appears to be a very local animal.

It is but of small size, being rather lower than the deer, but larger or thicker in body. The hair, in the male, is of a dusky red colour, extremely fine, and so long as to trail on the ground. Beneath the hair, is an extremely fine wool, which is said to be more beautiful than silk when manufactured into stockings and other articles. The horns are closely united at the base, bending inwards, but turning outwards towards the tips, which are very sharp.

V. Bos *Grunniens*, or yak, is about the height of an English bull, which he resembles in the general figure of the body, head, and legs; it is covered with a thick coat of long hair.

They are a very valuable property to the Tartars, who live in tents, and tend them from place to place: they at the same time afford their herdsmen an easy mode of conveyance, a good covering, and wholesome subsistence. Tents and ropes are manufactured of their hair: and amongst the humbler ranks of herdsmen, caps and jackets are made of their skins.

VI. Bos *Caffer*, or Cape ox, having large horns, inhabits the interior parts of Africa, north of the Cape of Good Hope, and is greatly superior in size to the largest English ox. It is of a very strong and muscular form, with a fierce and malevolent aspect. Its colour is a deep brown.

It is said to strip off the skin of such animals as it kills, by licking them with its rough tongue.

BOSEA, GOLDEN-ROD TREE: a genus of the digynia order, and pentandria class of plants; and in the natural method ranking under the 53d order, scabridæ. The calyx is pentaphyllous; there is no corolla, and the berry is monospermous. Of this genus there is but one species, viz.

Bosea yervamora. It is a native of the Canary and Caribbee islands, and is a strong woody shrub.

BOTANY, may be defined the science which teaches the knowledge of the vegetable kingdom. The word is derived from the Greek βοτανη, an herb; and this again may easily be traced to its primitive, βοω, or βοσκω, to feed: an apt derivation, since plants have ever been regarded as the food of a large portion of animals. The study of botany, then may be said to include—the practical discrimination, methodical arrangement, and systematical momenclature of vegetables.

The following article will serve to give the student a general idea of the subject, and prepare him for consulting with advantage the excellent work of Dr. Smith on Physiological and Systematical Botany, with other well known and approved productions on the same subject.

In describing the characters of plants, we shall treat of their roots, buds, trunk, leaves, props, inflorescence, fructification, and classification.

I. ROOTS are necessary to plants, to fix and hold them in the earth, from which they imbibe nourishment. Roots are either *annual*, or living for one season, as in barley; *biennial*, which survive one winter, and after perfecting their seed, perish at the end of the following summer, as wheat: or *perennial*, which remain and produce blossoms for an indefinite number of years, as those of trees and shrubs in general. The root consists of two parts, the *caudex* and the *radicula*. The *caudex* or stump is the body or knob of the root, from which the trunk and branches ascend, and the fibrous roots descend. The *radicula* is the fibrous part of the root branching from the *caudex*. Roots are: 1. *Fibrous*, or consisting entirely of fibres, as in many grasses and herbaceous plants. 2. *Creeping*, or having a subterraneous stem, spreading horizontally in the ground, throwing out numerous fibres, as in mint and couch-grass. 3. *Spindle-shaped*, as in the radish and carrot, which produce numerous fibres for the absorption of nutriment. 4. *Stumped*, or apparently bitten off, as in the primrose. 5. *Tuberous* or knobbed, as in the potatoe, which consists of fleshy knobs, connected by common stalks or fibres. 6 *Bulbous*, as in the crocus. 7. *Granulated*, having a cluster of little bulbs or scale connected by a common fibre, as in the saxifrage.

II. BUDS. These are, in most instances, guarded by scales, and furnished with gum or wooliness, as an additional defence. Buds are various in their forms, but very uniform in the same species, or even genus. They enfold the embryo plant.

III. TRUNK. The trunk of trees includes the stems or stalks, which are of seven kinds. The stem, as it advances in growth, is either able to support itself, or twines round other bodies. It is either *simple* as in the lily; or *branched* as in other plants. The parts are: 1. *Caulis*, the stem which bears both leaves and flowers, as the trunks and branches of all trees and shrubs, as well as of many herbaceous plants. 2. *Culmus*, a straw or culm, the peculiar stem of grasses, rushes, and similar plants. 3. *Scapus* or stalk, springs immediately from the root, bearing flowers and fruit, but not leaves, as in the primrose or cowslip. 4. *Pedunculus*, the flower-stalk, springs from the stem or branches, bearing flowers and fruit, but not leaves. 5. *Petiolus*, the foot-stalk, is applied exclusively to the stalk of a leaf.

IV. LEAVES. These are generally so formed as to present a large surface to the atmosphere. When they are of any other hue than green, they are said, in botanical language, to be *coloured*. The internal surface of a leaf is highly vascular and pulpy, and is clothed with a cuticle very various in different plants; but its pores are always so constructed as to admit of the requisite evaporation or absorption of *moisture*, as well as to admit and give out air. *Light* also acts through this cuticle, in a different manner. The effect of *moisture* must have been observed by every one. By absorption from the atmosphere, the leaves are refreshed; but by evaporation, especially when separated from their stalks, they soon fade and wither. The nutritious juices, imbibed from the earth and become *sap*, are carried by appropriate vessels into the substance of the leaves, and these juices are *returned* from each leaf, not into the wood again, but into the bark. The sap is carried into the leaves for the purpose of being acted upon by *air* and *light*, with the assistance of heat and moisture. By all these agents, a most material change is wrought in the component parts of the sap, according to the nature of the secretions elaborated, whether resinous, oily, mucilaginous, saccharine, bitter, acrid, or alkaline.

The *green* colour of the leaves is owing to the action of light, but they are subject to a disease by which they become partially spotted or streaked, and in this state are said to be variegated. The irritable nature of some leaves is very extraordinary. The *mimosa pudica* or sensitive plant, common in our hot-houses, when touched by any extraneous body, folds up its leaves, one after another, and the foot stalks droop as if dying.

V. Props or fulcra. These are: 1. *Stipula*, a leafy appendage to the true leaves, or to their stalks, for the most part in pairs. 2. *Bractia*, a leafy appendage to the flower, or to its stalk. 3. *Spina*, a thorn proceeding from the wood itself as in the wild pear tree, which loses its thorns by cultivation. 4. *Aculeus*, a prickle, proceeding from the bark only; as in the rose and bramble. 5. *Cirrus*, a tendril or clasper, is a support for weak stems by which they are enabled to climb rocks, or the trunks of lofty trees. 6. *Glandula*, a gland, is a small tumour, secreting a sweet, resinous, fragrant liquor, as on the calyx or cup of the moss-rose, and the foot stalks of passion flowers. 7. *Pilus*, a hair, which includes all the various kinds of pubescence · bristles, wool, &c. some of which discharge a poison, as in the nettle causing

great irritation wherever they are touched, so that their points may wound the skin.

VI. INFLORESCENCE, or the different kinds or modes of flowering, are, 1. *Verticillus*, a whorl, in which the flowers surround the stem in a garland or ring, as in the mints, dead-nettles, &c. 2. *Racunus*, a cluster, bears several flowers, each on its own stalk, like a bunch of currants. 3. *Spika*, a spike, is composed of numerous crowded flowers, ranged along an upright, common stalk, expanding progressively, as in wheat and barley. 4. *Corymbus*, a corymb, is a flat-topped spike as in the cabbage and wall-flower. 5. *Fasciculus*, a close bundle of flowers, as in the sweet william. 6. *Capitulum*, a head or tuft, as in the globe-amaranthus and thrift. 7. *Umbella*, an umbel consists of several stalks, called rays, spreading like an umbrella, as in parsley, carrot, and hemlock. 8. *Cyma*, a cyme, or stalks springing from a common centre, and afterwards irregularly subdivided, as in the laurustinus, and elder. 9. *Paniculus*, a panicle, a loose subdivided bunch of flowers, as in the oat. 10. *Thyrsus*, a bunch, is a very dense panicle inclining to an oval figure, as in the lilac.

VII. *Fructification.* Under this term are comprehended not only the parts of the fruit, but also those of the flower, which last are necessary for bringing the former to perfection. Fructification consists of seven parts, two only of which are *essential*, viz. *stamen* and *pistil*, since without them no plant can produce seeds. 1. *Calyx*, a flower cup, or external covering of the flower; to this belong the perianthium; involucrum; amentum, or cat-kin; spatha, or sheath; gluma, or husk; perichætium or scaly sheath; and volva, the wrapper. 2. *Corolla*, or little crown, is situated within the calyx, and consists in general of the coloured leaves of a flower,—the petalum, or petal, and the nectarium, or nectary, belonging to the corolla. 3. *Stamina*, the stamens, are various in number, in different flowers, and are situated within the corolla. The stamen consists of a filamentum, or filament, and the anthera, or anther. The cells of the latter contain the pollen or fecundating dust. 4. *Pistilla*, the pistils stand in the centre of the circle formed by the stamens, and consist of the germen or rudiments of the future fruit or seed; the style, which elevates the stigma; and the stigma which is destined to receive the pollen. 5. *Pericarpium*, the seed vessel, is formed from the germen enlarged, and is of the following kinds: a capsular or capsule; siliqua, or pod; legumen, or legume, the fruit of the pea-kind; drupa, stone-fruit; pomum, an apple, bacca, a berry; and strobilus, a cone. 6. *Semina*, the seeds, are composed of the embryo or germ, called by Linnæus, corculum, or little heart; the cotyledones, or seed-lobes almost universally two in number; albumen, the white; vitellus, the yolk; testa, the skin; and bilum, the scar.

Seeds are often accompanied by appendages or accessory parts; as, pellicula, the pellicle; arillus, the tunic; pappus, the seed-down; cauda, a tail; rostrum, a beak. To which may be added various spines, hooks, scales, and crests, generally serving to attach such seeds as are furnished with them, to the rough coats of animals, and thus promote their dispersion. 7. *Receptaculum*, the receptacle, is the base which receives the other parts of the fructification. It is *proper* when it supports the parts of a single fructification only; when it is a base to which only the parts of the flower are joined, and not the germen, it is called a receptacle of the flower; in this case the germen being placed below the receptacle of the flower, has a base of its own, which is called the receptacle of the fruit, and it is termed a receptacle of the seeds, when it is a base to which the seeds are fastened within the pericarpium. It is called *common* when it supports a head of flowers.

VIII. *Classification.* The system of Linnæus, now generally acknowledged and adopted, is founded on the number, situation, and proportion of the *stamens* and *pistils*, whose uses and structure have been just explained. The following twenty-four classes owe their distinctions principally to the stamens. 1. *Monandria*, one stamen. 2. *Diandria*, two stamina. 3. *Triandria*, three. 4. *Tetrandria*, four. 5. *Pentandria*, five. 6. *Hexandria*, six. 7. *Heptandria*, seven. 8. *Octandria*, eight. 9. *Enneandria*, nine. 10. *Decandria*, ten. 11. *Dodecandria*, twelve. 12. *Icosandria*, twenty or more stamina, inserted into the calyx. 13. *Polyandria*, all above twenty inserted into the receptacle. 14. *Didynamia*, four stamina, two long and two short. 15. *Tetradynamia*, six stamina, four long and two short. 16. *Monadelphia*, the stamina united into one body by the filaments. 17. *Diadelphia*, the stamina united into two bodies by the filaments. 18. *Polyadelphia*, the stamina united into three or more bodies by the filaments. 19. *Syngenesia*, anthers united into a tube. 20. *Gynandria*, stamens inserted either upon the style or germen. 21. *Monœcia*, stamens and pistils in separate flowers, but on the same plant. 22. *Diœcia*, stamens and pistils, like the former in separate flowers, but on two separate plants. 23. *Polygamia*, stamens and pistils separate in some flowers, united in others, either on one, two, or three distinct plants. 24. *Cryptogamia*, stamens and pistils, either not well ascertained, or not to be numbered with certainty.

The *orders*, or subdivisions of the classes are generally marked by the number of the pistils or by some other circumstances equally intelligible. The names of these as well as of the classes, are both of Greek derivation, and designate the functions of the respective organs.

In the following table the reader will find the names of the classes, and also those of the several orders which are included in each class.

TABLLE OF THE ORDERS.

Classes.	*Number and Names of the Orders.*
1. Monandria.	2. Monogynia, Digynia.
2. Diandria.	3. Monogynia, Digynia, Trigynia.
3. Triandria.	3. Monogynia, Digynia, Trigynia.
4. Tetrandria.	3. Monogynia, Digynia, Tetragynia.
5. Pentandria.	6. Monogynia, Digynia, Trigynia, Tetragynia, Pentagynia, Polygynia.
6. Hexandria.	5. Monogynia, Digynia, Trigynia, Tetragynia, Polygynia.
7. Heptandria.	4. Monogynia, Digynia, Tetragynia, Heptagynia.
8. Octandria.	4. Monogynia, Digynia, Trigynia, Tetragynia.
9. Enneandria.	3. Monogynia, Trigynia, Hexagynia.
10. Decandria.	5. Monogynia, Digynia, Trigynia, Pentagynia, Decagynia.
11. Dodecandria.	5. Monogynia, Digynia, Trigynia, Pentagynia, Dodecagynia.
12. Icosandria.	5. Monogynia, Digynia, Trigynia, Pentagynia, Polygynia.
13. Polyandria.	7. Monogynia, Digynia, Trigynia, Tetragynia, Pentagynia, Hexagynia Polygynia.
14. Didynamia.	2. Gymniospermia, Angiospermia.
15. Tetradynamia.	2. Siliculosa, Siliquosa.
16. Monadelphia.	8. Tirandria, Pentandria, Octandria, Enneandria, Decandria, Endecandria, Dodecandria, Polyandria.
17. Diadelphia.	4. Pentandria, Hexandria, Octandria, Decandria.
18. Polyadelphia.	4. Pentandria, Dodecandria, Icosandria, Polyandria.
19. Syngenesia.	6. Polygamia æqualis, Polygamia superflua, Polygamia frustrania, Polygamia necessaria, Polygamia segregata, Monogamia.
20 Gynandria.	9. Diandria, Triandria, Tetrandria, Pentandria, Hexandria, Octandria, Decandria, Dodecandria, Polyandria.
21. Monœcia.	11. Monandria, Diandria, Triandria, Tetrandria, Pentandria, Hexandria, Heptandria, Polyandria, Monadelphia, Syngenesia, Gynandria.
22. Diœcia.	15. Monandria, Diandria, Triandria, Tetrandria, Pentandria, Hexandria, Octandria, Enneandria, Decandria, Dodecandria, Icosandria, Polyandria, Monadelphia, Syngenesia, Gynandria.
23. Polygamia.	3. Monœcia, Diœcia, Triœcia.
24. Cryptogamia.	4. Filices, Musci, Algæ, Fungi.
Appendix.	1. Palmæ.

We cannot dismiss this article without expressing a strong desire that some one of our Botanical Professors would favour the public with a view of the beautiful system of Linnæus in an English dress. To the learned, it is true, this would be unnecessary; but it should be recollected that the study of botany, unlike the study of anatomy, is, as it were, by the great Author of nature, intended for the instruction of those who may be said to have scarcely any other medium of access to the rich stores of wisdom which this science displays. Why should the simple rustic who can read his native language be prevented by the appalling forms of a dead language, from feeling, in all its force, the lesson on the bounty and wisdom of his benevolent Maker, which he may read in those astonishing productions of nature, which, with so little concern, he every day treads under foot, or sees as if he saw them not?

BOTANY BAY, a bay on the east coast of New Holland, so called by Capt. Cook, from the great quantity of plants found there by Sir Joseph Banks, and Dr. Solander, in the year 1770. The bay is capacious, safe, and convenient: the harbour is about a quarter of a mile broad at the entrance. On the banks are great quantities of oysters, muscles, cockles, and other shell fish, which seem to form the principal article of food to the savages, who go into shoal water with their little canoes, and pick them out with their hands.

BOTTLE, a small vessel of glass, or other matter, with a narrow mouth to put liquor in. Bottles of glass are better for cyder than those of stone. It is a very common practice to clean wine bottles with leaden shot; but from its pernicious tendency it cannot be too strongly censured; several of the particles of the shot are by the necessary agitation in cleaning, often fixed in the bottom of the bottles, where they are slowly dissolved, and communicate a deleterious quality to the liquors. Instead of this a solution of potash is recommended, as being both cheaper, and more effectual, and perfectly safe. A very small portion of potash dissolved in warm water will celan two gross of bottles.

BOTTOM, in navigation, is used to denote as well the channel of rivers and harbours, as the body or hull of a ship: thus, in the former sense, we say, a gravelly bottom, clayey bottom, sandy bottom, &c. and in the latter sense, a British bottom, a Dutch bottom, &c. By statute, certain commodities imported in foreign bottoms, pay a duty called petty customs, over and above what they are liable to if imported in British bottoms.

BOTTOMRY, in commerce, a contract for the borrowing of money upon the keel or bottom of a ship; that is, when the master of a ship binds the ship itself, that if the money be not paid by the time appointed, the creditor shall have the ship.

BOTTOMRY is also where a person lends money to a merchant, and the lender is to be paid a greater sum at the return of the ship.

BOTTONY. A cross bottony, in heraldry, terminates at each end in three buds, knots, or buttons, resembling the trefoil.

BOTTS. See Oestris.

BOUNTY, in commerce, a premium paid by the government to the exporters of certain British commodities, on their taking oath, or, in some cases, giving bond, not to re-land the same in England.

BOW, a weapon of offence made of steel, wood, horn, or other elastic matter, which, after being bent by means of a string fastened to its two ends, in returning to its natural state, throws out an arrow with great force.

Bow *of a ship,* that part of her head which is contained between the stern and the after-part of the fore-castle, on either side; so that a ship hath two bows, the starboard and the larboard, or, as they are sometimes called, the weather and the lee bow.

BOW-*line,* in sea-language, a rope fastened near the middle of the leech, or perpendicular edge of the principal square sails, by three or four subordinate parts called bridles, and leading forward towards the bow, whence it derives its name. The use of the bow-line is to make the sail stand sharp or close, or by a wind.

BOWSPRIT, or *bolt-sprit,* a kind of mast, resting slopewise on the head of the main stem, and having its lower end fastened to the partners of the fore-mast, and farther supported by the fore-stay. It carries the sprit-sail, sprit-topsail, and jack-staff.

BOX, or *box-tree.* See Buxus.

BOYAU, in fortification, a ditch covered with a parapet, which serves as a communication between two trenches.

BRABEJUM, the *African almond,* a genus of the monœcia order and polygamia class of plants. Male corolla four or five parted; stamina four inserted in the throat; style bifid and abortive; the hermaphrodite has a four-parted corolla, revolute upwards with four stamina; one pistil with two stigmas. The fruit a roundish drupa, with a globular seed. The only species is the Brabejum stellatifolium, which is a native of the Cape of Good Hope.

BRACE, in architecture, a piece of timber framed in with bevil joints, the use of which is to keep the building from swerving either way. When the brace is framed into the kinglesses, or principal rafter, it is by some called a strut.

Braces, in the sea-language, are ropes belonging to all the yards of a ship, except the mizen, two to each yard, reeved through blocks that are fastened to penants, seized to the yard-arms. Their use is either to square or transverse the yards.

Brace, in writing, a term used to signify a crooked line, as }, made at the end of two or more articles in an account, the amount of which is usually placed in the centre of the brace.

BRACELET, an ornament worn on the wrist, much used among the ancients: it was made of different materials, and in different fashions, according to the age and quality of the wearer.

BRACKETS, in a ship, the small knees, serving to support the galleries, and commonly carved. Also, the timbers that support the gratings in the head are called brackets.

BRADS, among artificers, a kind of nails used in building, which have no spreading heads, as other nails have. They are distinguished, by ironmongers, by six names; as joiners'-brads, flooring brads, batten brads, bill-brads, or quarter-heads, &c.

BRADYPUS, or *sloth,* a genus of animals of the order of bruta. There are three species. 1. Bradypus tridactylus, or three-toed sloth. Its general appearance is very uncouth; the body is thick; the fore legs much shorter than the hinder; the feet small, but armed with three strong claws. The head is small, with a rounded or blunt snout, which is black and naked, the eyes are small; also the ears which are close to the head. The general colour of the hair which is coarse and thick, is a greyish brown. The sloth feeds entirely on vegetables, and makes a dismal yell, which frightens other animals from the spot. This animal is an inhabitant of South America. 2. Bradypus didactylus, or two-footed sloth, is also a native of South America, and of Ceylon. In its general appearance it resembles the former, only it has two claws on the fore-feet, and is more active. 3. Bradypus ursinus, or the ursine sloth, is a native of India, and very much resembles the bear. It is gentle and good natured, feeding chiefly on vegetables and milk, and is remarkably fond of apples.

BRAIL, or *brails,* in a ship, are small ropes made use of to furl the sails across: they belong only to the two courses and the mizen-sail.

BRAIN. See Anatomy.

BRAN, the skins or husks of corn, especially of wheat ground, separated from the corn by a sieve or boulter. It is of wheat bran that starch-makers make their starch. The dyers reckon bran among the non-colouring drugs, and use it for making the sour waters, with which they prepare their dyes.

BRANCHIÆ, *gills,* in the anatomy of fishes, the parts corresponding to the lungs of land-animals, by which fishes take in and throw out again a certain quantity of water impregnated with air. All fishes, except the cetaceous ones and the lamprey, are furnished with these organs of respiration, which are always eight in number, four on each side the throat.

BRANDY. This well known fluid is the spirit distilled from wine. The greatest quantities are made in Languedoc, where this manufacture, *so pernicious to society,* first commenced. It is obtained by distillation in the usual method by a still, which contains five or six quintals of wine, and has a capital and worm tube applied. Its peculiar flavour depends on the nature of the volatile principles, or essential oil, which come over along with it, and likewise, upon the management of the fire, the wood of the cask in which it is kept, &c. It is said, that our rectifiers imitate the flavour of brandy, by adding a small proportion of nitrous ether to the spirit of malt or molasses. See Alcohol.

BRASS. An elegant yellow-coloured compound metal, consisting of copper combined with about one-third of its weight of zinc. The best brass is made by cementation of calamine, or the ore of zinc, with granulated copper. See Copper.

BRASSICA, in botany, a genus of the tetradynamia siliquosa class and order. Natural order of siliquosa or cruciformes

cruciferæ, Jussieu. Essential character; calyx erect, converging; seeds globular; a gland between the shorter stamens and the pistil, and between the longer and the calyx. There are sixteen species, among which are the various kinds of cabbages, bore-coles, brocolis, and turnips.

BRAWN, the flesh of a boar soused or pickled; for which end the boar should be old; because the older he is, the more horny will the brawn be.

BRAZIL *wood*, in the arts. The tree which bears this wood is the cæsalpina crista. The wood is very hard, takes a high polish, and is so heavy as to sink in water. When chewed it gives a sweetish taste. It much resembles in appearance red saunders wood, but differs from [illegible] essentially in readily giving out its colour to water, which saunders wood does not.

Brazil wood is valuable for the beautiful orange and red colours, in various shades, which it furnishes to the dyer, but the colour is naturally very fugitive, though it may be to a certain degree fixed by various mordants.

BRAZING, the soldering or joining two pieces of iron together by means of thin plates of brass, melted between the pieces that are to be joined.

BREACH, in fortification, a gap made in any part of the works of a town by the cannon or mines of the besiegers, in order to make an attack upon the place. To make the attack more difficult, the besieged sow the breach with crow-feet, or stop it with chevaux de frize.

BREAD is a light porous spongy substance, prepared by fermentation and baking, from the flour of certain farinaceous seeds, especially wheat, and is the principal sustenance of man in the temperate regions of the northern hemisphere.

BREAKERS, a name given to those billows that break violently over rocks lying under the surface of the sea.

They are readily distinguished both by their appearance and sound, as they cover that part of the sea with a perpetual foam, and produce a hoarse roaring, very different from what the waves have in a deeper bottom.

BREECH, of a gun, the distance from the the hind part of the base ring to the beginning of the bore, it is always equal to the thickness of the metal at the vent.

BREWING is the art of making malt liquors, such as ale, beer, porter, &c. In this country the art of brewing is one of great importance, since fermented malt liquor forms the principal beverage of the inhabitants; and, indeed, it may be pronounced to be by far the most wholesome and nutritious of any of those liquors that are allowed to be essential to the support of the human frame; that is, provided it is produced from good materials, well managed during the process of preparation, and used in moderation. The process of brewing is differently conducted in different breweries, and is also varied in the same breweries, according to the nature and qualities of the liquor; but the following remarks will be found to be of general application to the art.

Before the malt is used it must be bruised, between rollers; and soft water is used for mashing and fermentation. The first step in brewing is mashing. This is done in a tub furnished with a false bottom, pierced with holes, and moveable, or fixed a few inches above the real bottom. There are two side-openings between the two; to one is fixed a pipe to convey water into the tun, and the other is used for drawing the liquor out. The malt is to be strewed over the false bottom, and a proper quantity of water let in from the upper copper; after which the mass is beaten by poles, or a machine like a rake or harrow, and moveable on a perpendicular beam with transverse arms for the rakes. When the mashing is completed, the tun is covered to prevent the escape of the heat, and the whole is suffered to stand, that the insoluble parts may separate from the liquor: the side-hole is then opened, and the clear wort discharged into the lower copper. The most eligible temperature in mashing is from 185 to 190 degrees, but for the first mashing the heat of the water must be less, and so in proportion to the dark colour of the malt.

The *wort* of the first mashing is always the richest in saccharine matter, but to exhaust the malt, a second and third mashing are requisite. *Thirty gallons* may be drawn from each bushel of malt, for sound small beer; *six and a half gallons* only for strong ale. Every bushel of malt absorbs, or retains, about three and a half gallons of water. The next process is *boiling and hopping;* and if only one kind of liquor is to be made, the produce of the three mashings is to be mixed; but if both ale and table beer are required, the wort of the first, or first and second mashings, is for the ale, and the remainder for the beer. The wort intended for the same liquor, after it comes from the tun, is put into the lower copper, and mixed with a proportion of hops; and the better the wort the more hops will be wanted. Hops contain gallic acid, and tanning matter, and deprive the sweet wort of the mucilage, which occasions the beer to keep without turning sour.

When the hops are mixed with the wort in the copper, the liquor is made to boil as fast as possible: after which it is discharged into shallow tubs, called *coolers*, where it remains till it is cool enough to undergo fermentation. From the coolers the liquor is transferred to the *working tun*, and with it is mixed a gallon of yeast to four barrels of beer. In four or five hours the fermentation begins, and it requires from 18 to 48 hours before the wort is fit to be barrelled. The fermentation still goes on in the barrels, and in a few days a copious discharge of yeast takes place from the bunghole, and the greater portion of gluten is disengaged. In brewing, the gluten is not wanted, but in bread it is indispensable, and alone renders it fit for use. Care must be taken to fill up the barrel every day with fresh liquor; this discharge lessens daily, and ends entirely in about a week, when the bunghole is closed, and the liquor is fit for use, after standing from a fortnight to three months, according to its strength, and the temperature at which it has been fermented. The fining of the beer is effected by the use of isinglass.

The following is a list of some of the unlawful substances seized at different breweries, and brewers' druggists' laboratories, in London, as copied from the minutes of the committee of

the House of Commons. Cocculus indicus multum, (an extract of the cocculus,) colouring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs. Sulphuric acid is very frequently added to *bring beer forward,* or make it hard, giving new beer instantly the taste of what is 18 months old. According to Mr. Accum, the present *entire* beer of the London brewer is composed of all the waste and spoiled beer of the publicans, the bottoms of butts, the leavings of the pots, the drippings of the machines for drawing the beer, the remnants of beer that lay in the leaden pipes of the brewery, with a portion of brown stout, bottling beer, and mild beer. He says that opium, tobacco, nux vomica, and extract of poppies, have been likewise used to adulterate beer.

BREYNIA, in botany, a genus of the polyandria diœcia class and order of plants. The essential character is, male cal. one-leaved, five parted; cor. none; nect. five glands; filaments five, very short; anthers roundish. Fem. cal. and cor. as in the male; pist. germ. globose; style none; stigmas five; per caps. five-celled; seeds solitary. There is one species, a native of New Caledonia.

BRICK. Among the numerous branches of the art of fashioning argillaceous earths into useful forms, and hardening them by fire, the art of making bricks and tiles is by no means one of the least useful.

Common clay is scarcely ever found in a state approaching to purity on the surface of the earth. It usually contains a large proportion of siliceous earth. Bergman examined several clays in the neighbourhood of Upsal, and made bricks, which he baked with various degrees of heat, suffered them to cool, immersed them in water for a considerable time, and then exposed them to the open air for three years. They were formed of clay and sand. The hardest were those into the composition of which a fourth part of sand had entered. Those which had been exposed for the shortest time to the fire were almost totally destroyed, and crumbled down by the action of the air. Such as had been more thoroughly burned, suffered less damage; and in those which had been formed of clay alone, and were half vitrified by the heat, no change whatever was produced.

A kind of bricks called *fire-bricks* are made from slate-clay, which are very hard, heavy, and contain a large proportion of sand. These are chiefly used in the construction of furnaces for steam-engines, or other large works, and in lining the ovens of glass-houses, as they will stand any degree of heat. Indeed, they should always be employed where fires of any intensity are required.

BRIDGE, an erection of masonry, timber, or iron, consisting of one or more arches, over a river, canal, or valley, for the convenience of crossing the same. The principal parts of a bridge are the piers, the arches, the pavement, the foot way on each side, the rail or parapet, and the butments or ends of the bridge on the bank.

The piers of stone bridges should be equal in number, that there may be one arch in the middle, where commonly the current is strongest; their thickness is not to be less than a sixth part of the arch, nor more than a fourth; they are commonly guarded in front with angular starlings, to break the force of the current. As the piers of bridges always diminish the bed of a river, in case of inundations, the bed must be sunk or hollowed in proportion to the space taken up by the piers (as the waters gain in depth what they lose in breadth) which otherwise conduce to wash away the foundation and endanger the piers: to prevent this, they sometimes diminish the current, either by lengthening its course, or making it more winding; or by stopping the bottom with rows of planks, stakes, or piles, which break the current.

For the figure of the arches, some prefer the semicircle, others the elliptical form, and some the catenarian arch; but the arch of equilibration is the only perfect one, being equally strong in every part.

Among the bridges of antiquity, that built by Trajan over the Danube, it is allowed, is the most magnificent. It was demolished by his next successor Adrian, and the ruins are still to be seen in the middle of the Danube, near the city Warhel, in Hungary. It had 20 piers, of square stone, each of which was 150 feet high above the foundation, 60 feet in breadth, and 170 feet distant from one another, which is the span or width of the arches; so that the whole length of the bridge was more than 1530 yards, or nearly one mile.

This however is trifling when compared with the famous flying bridge in China, built from one mountain to another, and consisting of a single arch 400 cubits long, and 500 cubits high. There are several bridges of considerable note in our own country. The triangular bridge at Crowland in Lincolnshire is supposed to be the most ancient Gothic structure in the kingdom; it was erected about the year 860. Of modern bridges, the two finest in Europe are the Westminster and Blackfriars bridges, over the Thames, at London.

The grandest invention in the whole history of bridge-building is, unquestionably, that of iron bridges, an invention which belongs exclusively to British artists. The first erected on a large scale is that over the river Severn, at Coalbrook Dale, in Shropshire. This bridge is composed of five ribs, and each rib of three concentric arcs connected together by radiating pieces. The interior arc forms a complete semicircle; but the others extend only to the cills under the road-way. These arcs pass through an upright frame of iron at each end, which serves as a guide; and the small space in the haunches between the frames and the outer arc is filled with a ring of about seven feet diameter. Upon the top of the ribs are laid cast-iron plates, which sustain the road-way. The arch of this bridge is one hundred feet six inches in span; the interior ring is cast in two pieces, each piece being about seventy feet in length.

The second iron bridge in this country was that constructed by Messrs. Walkers at Rotherham designed by Mr. Thos. Paine. This bridge after being exhibited for some time in a bowling green at Paddington was to have been sent to America but Mr. Paine not being able to pay the expense, the manufacturers took it

back, and the malleable iron was afterwards used in constructing the bridge at Wearmouth. The erection of the bridge at Wearmouth gave an impulse to public taste, and excited an emulation among artists which has produced many examples, and more projects of iron bridges; and at the present time there are some in progress which manifest great improvements in the art.

BRIEF, any writ issued out of any of the king's courts of record at Westminster, whereby any thing is commanded to be done in order to justice.

Brief also signifies an abridgment of the client's case made out for the instruction of counsel, on a trial at law, which is to be fully but briefly stated.

BRIGADE, in the military art, a party or division of a body of soldiers, whether horse or foot, under the command of a brigadier. An army is divided into brigades of horse and brigades of foot: a brigade of horse is a body of eight or ten squadrons; a brigade of foot consists of four, five, or six battalions.

BRIGADIER is the general officer who has the command of a brigade. The eldest colonels are generally advanced to this post. He that is upon duty is brigadier of the day.

BRIGANTINE, a small light vessel, which can both row and sail well, and is either for fighting or giving chace. It has about twelve or fifteen benches for the rowers, one man to a bench: all the hands aboard are soldiers, and each man has his musquet lying ready under his oar.

BRIMSTONE. See Sulphur. Casts of medals have been taken off on a composition of which the chief ingredient is sulphur, and hence they are called sulphur casts. By this means the most curious antiques may, to all useful purposes be indefinitely multiplied. The composition is this: melt eight ounces of sulphur over a gentle fire, and with it mix an equal quantity of fine vermilion, stir it well together, and it will dissolve like oil, then pour it into the mould, which is first to be rubbed over with oil. When cool it may be taken and touched over with aqua-fortis, it will look like fine coral.

BRISTLE, a rigid glossy kind of hair, found on swine, and much used by brush makers, shoe-makers, sadlers, and others. They are chiefly imported from Russia and Poland. There is a heavy duty upon these.

BRIZA, in botany, quaking grass: a genus of the digynia order, and triandria class of plants; and in the natural method ranking under the 4th order, gramina. There are six species of briza: two of which are natives of Britain, viz.

1. Briza media, the middle quaking grass, and,

2. Briza minor, the small quaking grass. Both grow in pasture grounds.

BROCADE, a stuff of gold, silver, or silk, raised and enriched with flowers, foliages, and other ornaments, according to the fancy of the merchants or manufacturers.

BROKER, a name given to persons of several and very different professions, the chief of which are exchange-brokers, stock-brokers, pawn-brokers, and brokers simply so called, who sell household furniture, and second-hand apparel.

Brokers, *exchange*, are a kind of agents, or negociators between merchants, and between merchants and tradesmen, in matters of bills of exchange, or merchandise, for which they have so much commission.

Brokers, *stock*, are those employed to buy and sell shares in the joint stock of a company, or in the public funds.

Brokers, *pawn*, are persons who keep shops, and let out money, to necessitous people, upon pledges, on interest.

BROKERAGE, the fee paid to a broker for his trouble in negociating business between person and person.

BROMELIA, in botany, so named in memory of Olaus Bromel, a Swede, a genus of the hexandria monogynia class and order. There are nine species, one of which B. ananas, or pine-apple, a fruit now so well known in Europe, and so much esteemed for the richness of its flavour, is produced from an herbaceous plant which has leaves somewhat resembling those of aloe, and for the most part serrate on their edges, but much thinner and not so succulent as those of the aloe. The fruit resembles, in shape, the cone of some species of the pine-tree, from which it takes the vulgar name of pine-apple.

BLOMUS, Broom-grass, a genus of the digynia order, and triandria class of plants and, in the natural method, ranking under the 4th order, gramina. There are 25 species, of which seven are natives of Britain.

BRONCHOCELE, in surgery, a tumour rising in the forepart of the neck. This disorder is frequently called a Derbyshire neck, on account of the inhabitants of that county being much subject to it: probably for the same reasons that the inhabitants about the valleys of the Alps, and other mountainous countries, are so much affected with it.

BRONZE. A mixed metal, consisting chiefly of copper, with a small proportion of tin, and sometimes other metals. It is used for casting statues, cannon, bells, and other articles, in all which the proportions of the ingredients vary.

BRONZING, the art of varnishing wood, plaster, ivory, &c. so as to give them the colour of bronze. There are two sorts of composition used for this purpose, the red and the yellow; the latter is made of the finest copper dust, and to the former is added a small quantity of red ochre, well pulverized. Both are applied with varnish, and the work is dried over a chafing-dish as soon as bronzed.

BROOM, in botany. See Spartium, and Genista.

BROWALLIA, in botany, a genus of the angiospermia order, in the didynamia class of plants. There are two species, both annuals, viz.

1. Browallia demissa, with a single flower upon each footstalk. The flowers are of a light blue colour, sometimes inclining to a purple or red.

2. Browallia elata, with one or many flowers on each footstalk, is a native of Peru.

BRUCEA, in botany, a genus of the tetrandria order, and dioecia class of plants. There is one species, a shrub of Abyssinia.

BRUCHUS, a genus of coleopterous insects, with filiform antennæ, equal filiform

feelers, and acuminated lip. The species of this genus are in all twenty-five.

BRUNFELSIA, in botany, a genus of the monogynia order, and pentandria class of plants. The corolla is funnel-shaped, and very long; and the fruit an unilocular polyspermous berry. There are two species.

Brunfelsia Americana, rises six or eight feet high, has a woody branching rough stem, with oblong entire leaves on footstalks, and large whitish flowers by threes or fours at the ends of the branches, succeeded by round saffron-coloured soft fruit.

BRUSH, an instrument made of bristles, hair wire, or small twigs, to clean clothes, rooms, &c. and also to paint with. There are various sorts of them, distinguished by their shape or use. Brushes in which the hairs are fastened with silver wire are very superior to those in which iron wire is used, especially where they are used in or with water. Brushes are used for medical purposes, in rheumatic affections of the joints, paralysis, &c.

BRYONIA, BYRONY, a genus of the syngenesia order, and monœcia class of plants; in the natural method ranking under the 34th order, cucurbitaceæ. The calyx of the male is five-toothed, with a quinquefid corolla, and three filaments. In the female the calyx is dentated, the corolla quadrifid, the style trifid, with a roundish many-seeded berry. There are 19 species, of which the most remarkable are:

1. Bryonia Africana, African tuberous-rooted bryony.

2. Bryonia alba, rough or white bryony with red flowers, a native of dry banks under hedges in many parts of Britain.

3. Bryonia Bonariensis, bryony with hairy palmated leaves, divided into five parts, and obtuse segments. It [illegible] a native of warm countries.

4. Bryonia Creti[illegible] spotted bryony of Crete.

5. Bryonia racemosa, bryony with a red olive-shaped fruit. It is a native of warm climates, and perennial.

6. Bryonia variegata, the American bryony with variegated fruit.

BRYUM, in botany, a genus of the 56th natural order, viz. musci, belonging to the cryptogamia class of plants. The anthera is operculated or covered with a lid, the calyptra polished, and there is a filament arising from the terminal tubercle. There are 41 species, most of them natives of England.

BUBO, or BUBOE. See SURGERY.

BUBON, MACEDONIAN PARSLEY; a genus of the digynia order, and pentandria class of plants; and in the natural method ranking under the 46th order, umbellatæ. The fruit is ovated, striated, and villous. There are five species, which are propagated by seeds, and require the common culture of other exotic vegetables, viz.

1. Bubon Galbanum, or African ferula. 2. Bubon Gummiferum. The Galbanum of the shops is supposed to come from these two species. 3. Bubon Macedonicum. 4. Bubon rigidus, or rigid ferula, is a native of Sicily. 5. Bubon Cavigattum.

BUBROMA, a genus of the class and order polyadelphia dodecandria. The essential character is calyx three-leaved: petals, five-arched, semibifid: anthers, on each filament, three: stigma, simple: capsule, muriate, ending in a five-rayed star.

There is one species, a large tree of the West Indies, resembling the elm.

BUCCINATOR. See ANATOMY.

BUCCINUM, the TRUMPET-SHELL, a genus of univalve shells, shaped, in some degree, like a horn, or other wind instrument.

This is a very numerous genus, the principal species of which are the pomum, spindle-shell, the mitre-shell, the Midas-ear-shell, the great Triton-shell, the tower of Babel-shell, &c.

BUCCO, the *barbet*, in natural history, a genus of birds of the order picæ. Generic character; bill sharp-edged, compressed on the sides, notched on each side near the apex, bent inwards, with a long slit beneath the eyes; nostrils covered with incumbent feathers; feet formed for climbing. This bird is found in Brazil and Cayenne, is clumsy in its shape, and pensive and solitary in its manners. It is so lethargic in its disposition, that it will suffer itself to be shot at several times before it attempts to escape.

BUCEROS, the *hornbill*, in natural history, a genus of birds of the order picæ. Generic character: their bill is convex, curved, sharp-edged, large, outwardly serrate, with a horny protuberance near the base of the upper mandible; the nostrils are behind the base of the bill; the tongue is sharp-pointed and short; the feet gressorial. There are sixteen species enumerated by Gmelin, though Latham reckons only four; of these the most curious is, the B. Abyssinicus, or Abyssinian hornbill This is found in the country from which it takes its name, principally among fields of jaff, and nourishes itself by the green beetles which abound in them.

BUCHNERA, in botany, a genus of the angiospermia order, in the didynamia class of plants; ranking, in the natural method, under the 40th order, personatæ. There are eleven species, natives of the Cape, South America, and the West Indies.

BUCIDA, in botany, a genus of the order monogynia, in the decandria class of plants; ranging, in the natural method, under the 12th order, holoraceæ.

BUCK, in natural history, a male horned beast, whose female is denominated a doe See CERVUS.

BUCKET, a small portable vessel to hold water, often made of leather for its lightness and easy use in cases of fire. It is also the vessel let down into a well, or the sides of ships, to fetch up water.

BUCKING, the first operation in the whitening of linen-yarn or cloth: it consists in pouring hot water upon a tubful of yarn, intermingled with several strata of fine ashes of the ash tree. See BLEACHING.

BUCKLER, a piece of defensive armour used by the ancients. It was worn on the left arm, and composed of wickers woven together, or wood of the lightest sort, but most commonly of hides, fortified with plates of brass or other metal.

BUCKRAM, in commerce, a sort of coarse cloth made of hemp, gummed, calendered, and dyed several colours. It is put into those places of the lining of a garment, which are to be stiff and to keep their forms.

BUCK-*wheat*. See POLYGONUM

BUCKTHORN. See RHAMNUS.

BUDDING, a method of propagating various sorts of trees, particularly those of the wall-fruit kinds. See GARDENING.

BUDDLEIA, in botany, so named in honour of Adam Buddle, a genus of the monogynia order and tetrandria class of plants. Calyx and corolla quadrifid; and the stamina at the incisures of the corolla. Capsule bisulcated, bilocular, and polyspermous. There are eight species, the principal of which are, 1. *Buddleia Americana*, a native of the West Indies. It is a shrub, which grows ten or twelve feet high. 2. *Buddleia* occidentalis, a native of Carthagena. This grows to a greater height than the former, and has numerous branches. 3. *Buddleia* globosa is a native of Chili. It is a beautiful shrub, and the flowers are of an orange colour.

BUFF, in commerce, a sort of leather prepared from the skin of the buffalo, dressed with oil, after the manner of shammy. This forms a considerable article in commerce all along the coast of Africa.

BUFFALO. See BOS.

BUFO, the *toad*. See RANA.

BUFONIA, *toad grass*: a genus of the digynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 22d order, caryophylleæ. The calyx is four leaved; the corolla, four petalled; the capsule is monospermous. There is but one species, a native of Britain.

BUG. See CIMEX.

BUILDING. See ARCHITECTURE.

BUILDINGS, *laws concerning*. The buildings of London are regulated by what is denominated the building-act, which repeals and amends several former acts for the same purpose. Surveyors of districts are appointed to see the rules and regulations of this act properly complied with. Before any building is begun to be erected, the master workman is bound to give twenty-four hours' notice to the surveyor, who is to attend and view the building, and enforce the observance of the act.

BULBOCODIUM, *mountain-saffron*: a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the ninth order, spathaceæ. The corolla is funnel-shaped, and hexapetalous, with the heels narrow, supporting the stamina. There is one species, Bulbocodium vernum, which is a native of Spain, and has a bulbous root.

BULIMY, a disease in which the patient is affected with an insatiable desire of eating; and, unless he is indulged, he often falls into fainting fits. It is also called *fames canina*, canine appetite.

BULK-*heads* are partitions made athwart the ship, with boards, by which one part is divided from the other; as the great cabin, gun-room, bread-room, and several other divisions.

BULL. See BOS.

BULL, among ecclesiastics, a written letter dispatched by order of the Pope, from the Roman chancery, and sealed with lead, being written on parchment, by which it is partly distinguished from a brief.

BULL-*finch*. See LOXIA.

BULLA, in conchology, the name of a genus of shells, the character of which is thus defined: animal a limax; shell univalve, convoluted, and unarmed; mouth or aperture somewhat straightened, oblong, longitudinal, and at the base very entire; pillar lip oblique, and smooth. There are many species.

BULLION, uncoined gold or silver in the mass.

Those metals are called so, either when smelted from the native ore, and not perfectly refined, or when they are perfectly refined but melted down in bars or ingots, or in any unwrought body of any degree of fineness.

BUMALDA, in botany, a genus of the digynia order, belonging to the pentandria class of plants. The corolla is five-petalled, styles villose, capsule two-celled, two-beaked. There is one species, a native of Japan.

BUMELIA, a genus of the class and order pentandria monogynia. Corolla five-cleft, with five-leaved nectary, drupe one-seeded. There are seven species, all trees and shrubs, natives of the West Indies.

BUNIAS, in botany, a genus of the order siliquosa, and tetradynamia class of plants, and ranking under the thirty-ninth natural order, siliquosæ. The siliqua is deciduous, four-sided, muricated, or shagreened with unequal pointed angles. There are nine species, all annual plants.

BUNIUM, *pig-nut*, or *earth-nut*, a genus of the digynia order and pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The corolla is uniform, the umbel thick, and the fruit ovate. There is but one known species, viz. Bunium bulbocastanum, with a globular root. It grows naturally in moist pastures in Britain, and has a tuberous solid root, which lies deep in the ground.

BUNT *of a sail*, the middle part of it, formed designedly into a bag or cavity, that the sail may gather more wind. It is used mostly in top-sails, because courses are generally cut square, or with but small allowance for bunt or compass.

BUNT *lines* are small lines made fast to the bottom of the sails, in the middle part of the bolt-rope, to a cringle, and so are reeved through a small block, seized to the yard. Their use is to trice up the bunt of the sail, for the better furling it up.

BUOY, at sea, a short piece of wood, or a close-hooped barrel, fastened so as to float directly over the anchor, that the men who go in the boat to weigh the anchor, may know where it lies.

BUOY is also a piece of wood or cork, sometimes an empty cask, well closed, swimming on the surface of the water, and fastened by a chain, serving to mark the dangerous places near a coast.

BUPHAGA, in ornithology, a genus of the order of picæ, of which only a single species, (the Africana) has been discovered. It is found in Africa, and is called in English, the beef-eater, from this peculiarity, that it sometimes alights upon the backs of the cattle, and picks holes in them to get at the larvæ of the œstri, or gad-flies, deposited by those creatures in the flesh directly below the skin.

BUPHTHALMUM, *ox-eye*, a genus of the polygamia superflua order, and syngenesia class of plants, and in the natural method

ranking under the 49th order, compositæ. The receptacle is paleaceous; the pappus an indifferent rim; the seeds, emarginated on the sides; the stigmata of the hermaphrodite florets undivided. There are twelve species, all of which may be propagated by seeds. The following are the most remarkable:

1. Buphthalmum arborescens, rises with several woody stems to the height of eight or ten feet. The flowers are produced at the ends of the branches; they are of a pale yellow colour.

2. Buphthalmum helianthoides, a native of North America. It has a perennial root and an annual stalk, which rises six or eight feet high. The flowers are of a bright yellow colour.

BUPLEURUM, *hare's ear*, or *thorough-wax*, a genus of the digynia order, and pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The involucra of the partial umbels are large in proportion, and pentaphyllous; the petals involuted; the fruit roundish, compressed and striated. There are 14 species, the principal of which is, bupleurum fruticosum, or shrubby Ethiopian hartwort. It rises with a shrubby stem, five or six feet high, adorned with oblong, oval, entire leaves of a sea-green colour, placed alternately, with yellow flowers in umbels at the ends of the branches. It may be propagated by cuttings.

BUPRESTIS, a genus of coleopterous insects, distinguished by the uncommon brilliancy of their colours, which emulate the finest and most beautifully polished metals. The insects of this genus have the antennæ serrated, and as long as the thorax; feelers four, which are all filiform; head partly retracted within the thorax. The larvæ of the buprestes are said to live in the solid wood, or in the trunks of decayed trees; there are 27 species.

BURCARDIA, a genus of the class and order pentandria pentagynia. The essential character is, calyx five-leaved; corolla five-petalled; capsule angular, one-celled, three-valved, seven or eight-seeded. There is one species, a native of Guiana, annual.

BURDEN *of a ship* is its contents, or number of tons it will carry. The burden of a ship may be determined thus: multiply the length of the keel, taken within board, by the breadth of the ship, within board, taken from the midship-beam, and multiply the product by the depth of the hold, and divide the last product by 94, the quotient is the content of the tonnage required.

BURGESS, an inhabitant of a borough, or one who possesses a tenement therein. In other countries, burgess and citizen are confounded together; but with us they are distinguished: the word is also applied to the magistrates of some towns. Burgess is now ordinarily used for the representative of a borough-town in parliament.

BURGLARY, the breaking and entering the mansion-house of another in the night, with intent to commit some felony within the same, whether the felonious intent be executed or not. There must be a breaking and entry to complete this offence. If there be day-light enough to discern a man's face, it is no burglary.

BURGUNDY *pitch*, in medicine, the juice of the pinus abies, boiled in water, and strained through a linen cloth. It is chiefly employed for external purposes in inveterate coughs, &c.

BURIAL, the interment of a deceased person. The rites of burial make the greatest and most necessary care, being looked upon in all countries, and at all times, as a debt so sacred, that such as neglected to discharge it were thought accursed.

Burials, in law, persons are to be buried in woollen, or their representatives shall forfeit 5*l.* and affidavit is to be made thereof before a justice under a like penalty.

BURMANNIA, a genus of the monogynia order, in the hexandria class of plants; ranked in the natural method under the 10th order, coronariæ. The flower is small, and consists of three minute, ovated, oblong petals, situated at the mouth of the cup; the fruit is an involuted capsule, formed of three valves, with three cells, containing many small seeds. There are two species, of no note.

BURNING-*glass*, a convex or concave glass, commonly spherical, which being exposed directly to the sun, collects all the rays falling thereon into a very small space, called the focus; where wood, or any other combustible matter being put, will be set on fire.

The most remarkable burning-glasses, among the ancients, were those of Archimedes and Proclus; by the first of which the Roman ships besieging Syracuse, according to the testimony of several writers, and by the other, the navy of Vitalian besieging Byzantium, were reduced to ashes.

The best instrument of this kind known in modern times, was constructed by Mr. Parker of Fleet Street, at an expense of upwards of seven hundred pounds. It exposed a surface of 2 feet 8½ inches, when fixed in its frame.

BURN, in medicine and surgery, an injury received in any part of the body, either by fire itself, or by instruments put in a violent heat by the fire.

BURNISHER, a round polished piece of steel, serving to smoothe and give a lustre to metals.

Of these there are different kinds of different figures, straight, crooked, &c. Half burnishers are used to solder silver as well as to give a lustre.

BURR *pump*, or **Bildge** *pump*, differs from the common pump in having a staff, 6, 7, or 8 feet long, with a bar of wood whereto the leather is nailed, and this serves instead of a box. Two men standing over the pump thrust down this staff, to the middle whereof is fastened a rope for six, eight, or ten to hale by, thus pulling it up and down.

BURSERA, in botany, a genus of the diœcia polygamia class and order. The hermaphrodite calyx is triphyllous; the corolla tripetalous; the male capsule carnous; trivalved, and monospermous. The male is, corolla five-petalled, stamina, ten. There is but one species, viz.

Bursera gummifera, or gum elemi. It is found in abundance in woods in most of the Bahama islands, and grows in a very short time to a considerable height and thickness. The bark is brown, and very like the birch. It has yellow flowers, male and female on different trees. These are succeeded by purple

coloured berries, hanging in clusters. The seed is hard, white, and of a triangular figure, inclosed within a thin capsule. The fruit, when cut, discharges a clear balsam, esteemed a good vulne [illegible] for horses. On wounding the bark, a thick milky liquor is obtained, which concretes into a resin no way different from the gum elemi of the shops.

BUSHEL, a measure for dry goods, containing four pecks or eight gallons, or one-eighth of a quarter. A bushel, by 12 Henry VIII. c. 5, is to contain eight gallons of wheat: the gallon eight pounds troy-weight; the ounce twenty sterlings, and the sterling thirty-two grains, or corns of wheat, in the midst of the ear.

This standard bushel is kept in the exchequer. By act of parliament made in 1697, it is determined that every round bushel with a plain and even bottom, being 18½ inches in diameter, and 8 inches deep, should be esteemed a legal Winchester bushel.

BUSKIN, a kind of shoe, somewhat in the manner of a boot, and adapted to either foot, and worn by either sex. This part of dress, covering both the foot and mid-leg, was tied underneath the knee; it was very rich and fine, and principally used on the stage by actors in tragedy.

BUST, or Busto, in sculpture, &c. a term used for the figure or portrait of a person in relievo, shewing only the head, shoulders, and stomach, the arms being lopped off: it is usually placed on a pedestal or console.

BUTEA, in botany, a genus of the diadelphia decandria class and order. Calyx slightly two-lipped; corolla with a very long lanceolate banner; legume compressed, membranaceous; one-seeded at the tip. Two species; viz. Frondosa and Superba, found on the coast of Coromandel.

BUTNERIA, a genus of the pentandria monogynia class and order. Cor. five-petalled, filaments at top, connate with the petals; caps. five-grained, muricate. There are three species, shrubs of America and the West Indies.

BUTT, in commerce, a measure of wine containing two hogsheads, or 126 gallons.

Butt, or *butt-ends*, in the sea-language, are the fore-ends of all planks under water, as they rise, and are joined one end to another.

BUTTER, a fat unctuous substance, prepared from milk by churning. It was late before the Greeks appear to have had any notion of butter; their poets make no mention of it, and yet frequently speak of milk and cheese. The Romans used butter no otherwise than as a medicine.

BUTTON, an article of dress, serving to fasten clothes tight about the body, made of metal, silk, mohair, &c. in various forms. Metal buttons are formed two different ways; the blanks, or bases of the button, are either pierced out of a large sheet of metal, or cast. In the latter case, the shanks are previously fixed in the sand, exactly in the centre of the impression formed by each pattern, so as to have their extremities immersed in the melted metal, by which means they are firmly fixed in the button when cooled. The former process is generally used for yellow buttons, and the latter for those of white metal.

BUXBAUMIA, in botany, a genus of the natural order musci, and belonging to the cryptogamia class of plants.

BUXUS, the *box-tree*, a genus of the tetrandria order and monœcia class of plants ranking in the natural method under the 38th order, tricoccæ. Male calyx triphyllous; the germen an embryo. Female calyx tetraphyllous; petals three and styles three; capsule three beaked, and trilocular with two seeds. There is one species with three varieties. Buxus angustifolia, or the narrow-leaved box. 2. Buxus arborescens, with oval leaves. These two grow in abundance upon Boxhill, near Dorking in Surrey. There are two or three varieties of the second sort, one with yellow and the other with white striped leaves. Box wood is hard and smooth. It is used for rules, scales, quadrants, combs, &c. 3. Buxus suffruticosa or Dutch box, commonly used for bordering in flower gardens.

BUZZARD. See Falcon.

BY-LAW, is a private law made by those who are duly authorised so to do by charter, prescription, or custom, for the preservation of order and good government, within some particular place or jurisdiction. Moor, 583.

BYSSUS, in botany, a genus of the cryptogamia algæ, and the last in the scale of vegetation in that class. These mosses are composed of simple and uniform parts, and appear in the form of threads on rotten wood, rocks, and walls, and especially in damp cellars.

BYSTROPOGON, in botany, a genus of the didynamia gymnospermia class and order. The essential character is; calyx five-subulate, bearded at the opening; corolla, upper lip bifid; covers trifid; stamens distant. There are seven species.

C.

C, the third letter, and second consonant of the alphabet. It has two sounds, hard and soft; hard, like *k* before *a*, *u*, *o*, *l*, and *r*; as in call, cost, cup, clean, crop; and soft, like *s* before *i*, *e*, and *y*; as in city, cession, cyder: before *h* it has a peculiar sound, as in chance, chalk: in chord, chart, and some other words, it is hard like *k*: but in many French words it is soft before *h*, like *s*, as chaise, chagrin.

As a numeral, C signifies 100, CC 200, &c.

C, in music, the highest part in the thorough bass; again, a simple C, or rather a semicircle, placed after the cliff, intimates, that the music is in common time, which is either quick or slow; as it is joined with

allegro or adagio: if alone, it is usually adagio.

CABBAGE. See Brassica.

CABBALA, properly signifies tradition, and is the name of a mysterious kind of science, thought to have been delivered by revelation to the ancient Jews, and transmitted by oral tradition to those of our times; serving for the interpretation of the books both of nature and scripture.

CABLE, a strong rope, commonly of hemp, which serves to keep a ship at anchor. There is no merchant ship, however small, but has at least three cables. Every cable, of what thickness soever it may be, is composed of three strands, every strand of three ropes, and every rope of three twists; the twist is made of more or less threads, according as the cable is to be thicker or thinner. In the manufacture of cables, after the ropes are made, they use sticks, which they pass first between the ropes of which they make the strands, and afterwards between the strands of which they make the cable.

CABLED, in heraldry, a term applied to a cross formed of the two ends of a ship's cable.

CABOCHED, in heraldry, is when the heads of beasts are borne without any part of the neck, full faced.

CACALIA, in botany, Alpine colt's-foot, a genus of the polygamia æqualis order, and syngenesia class of plants. The receptacle is naked: the pappus hairy: the calyx cylindrical, oblong, and calyced. There are 33 species: the most remarkable are:

1. Cacalia ficoides, a native of the Cape of Good Hope; the leaves are pickled by the French, who esteem them much.

2. Cacalia kleinia, with a compound shrubby stalk. It grows naturally in the Canary islands, but has long been cultivated in the English gardens.

CACHEXY, in medicine, such a disposition of the body as depraves the nourishment throughout its whole habit.

CACHRYS, a genus of the digynia order, and pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. There are five species, viz. 1. Cachrys hungarica, with a plain, fungous, channelled seed. 2. Cachrys libanotis, with smooth furrowed seeds. 3. Cachrys linearis, with plain channelled fruit. 4. Cachrys sicula, with doubled-winged leaves. 5. Cachrys trifida, with bipinnated leaves. All these are perennial plants, rising high, and bearing large yellow flowers.

CACTUS, *melon thistle:* a genus of the monogynia order, and icosandria class of plants; and in the natural method ranking under the 13th order, succulentæ. The calyx is monophyllous, superior, or above the receptacle of the fruit, imbricated; the corolla polypetalous; the fruit an unilocular polyspermous berry. When the plants are cut through, their inside is a soft, pale-green, fleshy substance, very full of moisture. The taste is agreeably acid, which, in a hot country, must render them grateful. There are 27 species, all natives of the West Indies. The two following are the most remarkable, viz. 1. Cactus cochenillifer, the species which the cochineal insects inhabit. 2. Cactus grandiflora, one of the creeping cereuses. The flower of this species, though very short-lived, is as beautiful as any in the vegetable system.

CADET is a military term, denoting a young gentleman who chooses to carry arms in a marching regiment as a private soldier. His views are to acquire some knowledge in the art of war, and to obtain a commission in the army.

CÆCILIA, the name of a genus of serpents. The generic character is, that the body is without scales, is smooth, and moves by means of lateral rugæ or wrinkles; the upper lip is prominent, and furnished with two tentacula; it has no tail. There are three species, viz. 1. Cæcilia tentaculata, the eel-shaped cæcilia: it is about a foot long, and of a brown colour, but the belly is white. It is a native of South America. 2. Cæcilia glutinosa, the white-sided cæcilia, is about the same size as the preceding, and also of a brown colour, only it has a white stripe along each side. 3. Slender cæcilia, is about 14 inches long, and the skin minutely granulated.

CÆSALPINIA, Brasiletto, or Brasilwood, a genus of the decandria class, and monogynia order of plants; and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquefid, with the lowest segment larger in proportion. There are five petals, the lowest most beautiful. It is a leguminous plant. There are eight species.

CÆSARIAN *section,* in midwifery, an operation, by which the fœtus is delivered from the womb of its mother, when it cannot be done in the natural way.

CÆSURA, in the ancient poetry, is when, in the scanning of a verse, a word is divided so that one part seems cut off, and goes to a different foot from the rest; as,

Menti ri no li, nun quam men dacia prosunt.

CÆTERIS *paribus,* a Latin term, often used by mathematical and physical writers. the words literally signifying "the rest, or the other things, being alike, or equal."

CAIRN, a heap of stones thrown together, generally in a conical form, differing from barrows only in regard to the materials of which they are formed; the design of both appears to have been the same. Cairns are more common in Scotland and Wales than in England, evidently from the facility with which stones are procured in those countries.

CAISSON, in the military art, a wooden chest, into which several bombs are put, and sometimes only filled with gunpowder. This is buried under some work, of which the enemy intend to possess themselves; and when they are masters of it, is fired, in order to blow them up. It is also employed for a wooden frame, used in laying the foundations of the piers of a bridge.

CALAMANCO, a sort of woollen stuff manufactured in England and in Brabant. It has a fine gloss, and is chequered in the warp. Some are quite plain, others have broad stripes with flowers; some with plain broad stripes, some with narrow stripes, and others watered.

CALAMINARIS, or Lapis Calaminaris, in natural history, an ore of zinc, of a spongy substance, and a lax and cavernous texture, yet considerably heavy.

CALAMUS, a genus of the monogynia order, and hexandria class of plants; and in the natural method ranking under the 5th order.

tripetaloideæ. The calyx is hexaphyllous, there is no corolla, the fruit is a dry monospermous berry, imbricated backwards. There is but one species, viz.

Calamus rotang. The stem is without branches, has a crown at top, and is everywhere beset with straight spines. This is the real Indian cane, and grows in Sumatra.

CALCINATION. The fixed residues of such matters as have undergone combustion are called cinders in common language, and calces, or now more commonly oxides, by chemists; and the operation, when considered with regard to these residues, is termed calcination. In this general way it has likewise been applied to bodies not really combustible, but only deprived of some of their principles by heat. Thus we hear of the calcination of chalk, to convert it into lime, by driving off its carbonic acid and water; of gypsum or plaster stone, of alum, of borax, and other saline bodies, by which they are deprived of their water of crystallization; of bones, which lose their volatile parts by this treatment; and of various other bodies.

CALCULUS or Stone. This name is generally given to all hard concretions, not bony, formed in the bodies of animals. Of these, the most important, as giving rise to one of the most painful diseases incident to human nature, is the *urinary calculus* or stone in the bladder. Different substances occasionally enter into the composition of this calculus, but the most usual is the lithic acid.

Urinary calculi are usually spheroidal, sometimes they are polygonous, or resemble a cluster of mulberries. Their size is various; sometimes they are very small, and sometimes as large as a goose-egg. The colour of some of them is a deep brown. In some cases they are white; in others, of a dark grey. Their surface in some cases is polished like marble; in others, rough and unequal; sometimes they are covered with semi-transparent crystals.

Calculus *differentialis*, a method of differencing quantities, or of finding an infinitely small quantity, which being taken an infinite number of times, shall be equal to a given quantity. An infinitely small quantity, or infinitesimal, is a portion of a quantity less than any assignable one; it is therefore accounted as nothing; and hence two quantities only differing by an infinitesimal, are reputed equal. The word infinitesimal is merely respective, and implies a relation to another quantity. Infinitesimals are likewise called differentials, when they are considered as the differences of two quantities. Sir Isaac Newton calls them moments, considering them as momentry increments of quantities. The calculus differentialis, therefore, and the doctrine of fluxions, are the same thing, under different names, the latter given by Sir Isaac Newton, and the former by Mr. Leibnitz, who disputes with Sir Isaac the honour of the discovery. There is, however, one difference between them, which consists in the manner of expressing the differentials of quantities: Mr. Leibnitz, and most foreigners, express them by the same letters as variable ones, prefixing only the letter d: thus the differential of x is called dx, and the differential of y, dy: and dx is a positive quantity if x continually increase; and negative quantity if x decrease. We, on the other hand, following Sir Isaac Newton, instead of dx, write $\dot{x}$, (with a dot over it), and instead of dy, $\dot{y}$. See Fluxions.

Calculus *exponentialis*, among mathematicians, a method of differencing exponential quantities, and summing up the differentials of exponential quantities. By an exponential quantity is meant a power, the exponent of which is variable, as x^x, a^x. In order to difference an exponential quantity, nothing else is required than to reduce the exponential quantities to logarithmic ones, upon which the differencing is managed as in logarithmic ones.

Calculus, *integralis* or *summatorius*, is the method of summing up differential quantities, and the inverse of the calculus differentialis. It is applied to geometry, in the quadrature and rectification of curves, in cubing solids and measuring their surfaces, in the inverse method of tangents and in the doctrine of logarithms.

Calculus, *antecedental*, a geometrical method of reasoning, without regarding motion, and applicable to every purpose of fluxions. It was the invention of Mr. Glenie, who derived it from examining the antecedents of ratios with given consequents, and a given standard of comparison in the several degrees of augmentation and diminution which they undergo by composition and decomposition.

CALEA, a genus of the polygamia æqualis order, and syngenesia class of plants, in the natural method belonging to the 49th order, compositæ. Receptacle paleaceous, the pappus hairy, and calyx imbricated. There are seven species.

CALENDAR, a distribution of time, accommodated to the various uses of life, but more especially such as regard civil and ecclesiastical polity; in which sense it differs nothing from the modern almanacs. See Chronology.

CALENDER, a machine used in manufactories, to press certain woollens, &c. to make them even, smooth, and glossy, or to give them waves, or water them. This instrument is composed of two thick cylinders, of very hard wood, round which the stuffs to be calendered are wound: these are placed crossways between two very thick boards, the lower serving as a fixed base, and the upper moveable, by means of a thick screw, with a rope fastened to a spindle, which makes its axis: the uppermost board is loaded with large stones cemented together, weighing 20,000*lb.* or more. It is this weight that gives the polish.

CALENDS, a Roman chronology, the first day of each month, so called from the Greek καλειν to proclaim: it being customary on those days to proclaim the number of holydays in each month. The calends were reckoned backwards: thus, the first of May begins the calends of May; the 30th of April was the second of the calends of May; the 29th, the 3d, &c. to the 13th where the ides commence; which are also numbered in a retrograde order to the 5th, where the nones begin, and these are numbered after the same manner to the first of the month, which is the calends of April.

CALENDULA, in botany, the *marigold*, a genus of the polygamia necessaria order, in

the ral method ranking under the 49th order, compositæ. The receptacle is naked, there is no pappus, the calyx is polyphyllous and equal, the seeds of the disk membranaceous. There are 14 species, none of them natives of Europe. The common kind is so well known as to need no description.

CALENTURE, in medicine, a feverish disorder incident to sailors in hot climates; the principal sympton of which is, their imagining the sea to be green fields: hence, attempting to walk abroad in these, they are frequently lost.

CALIBER *compasses*, the name of a particular instrument used by gunners for measuring the diameters of shot, shells, &c. as also the cylinder of cannon, mortars, and howitzers. They resemble other compasses, except in their legs, which are arched, in order that the points may touch the extremities of the arch. To find the true diameter of a circle, they have a quadrant fastened to one leg, and passing through the other, marked with inches and parts, to express the diameter required: the length of each ruler or plate is usually between the limits of six inches and a foot. On these rulers are a variety of scales, tables, proportions, &c.

CALICO, a kind of manufacture made of cotton. It takes its name from Callicut, a city on the coast of Malabar, where it was first manufactured. In the East Indies the calicoes are all painted by the hand, which is performed with great expedition.

CALICO *printing;* the art of dyeing cloth (chiefly cotton and linen) topically; that is, impressing figures, in one or more colours, on certain parts of the cloth, while the rest of the surface is left in its original state. See DYEING.

CALLA, *African* or *Ethiopian arum*, a genus of the polyandria order, and gynandria class of plants, ranking in the natural method under the second order, piperitæ. There are four species; the most beautiful of which is the Calla Æthiopica, which is a native of the Cape of Good Hope.

CALLICARPA, a genus of plants of the class and order tetrandria monogynia. Calyx four-cleft; corolla four-cleft; berry four-seeded. There are seven species, all shrubs, natives of America and the West Indies.

CALLIGONUM, in botany, a genus of the polyandria digynia class of plants, without a flower: the fruit is an oval, compressed, striated, hairy pericarpium, with bifid tops, turning backwards; the seed single. There are three species.

CALLISIA, in botany, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the 6th order, ensatæ. The calyx is triphyllous; the petals are three; the antheræ are doubled; and the capsule is bilocular. There is but one species, a native of America.

CALLITRICHE, or *star-grass*, in botany, a genus of the digynia order, in the monandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. It has no calyx, but two petals, and the capsule is bilocular and tetraspermous. There are 2 species.

CALLUS, or *Callosity*, any cutaneous, corneous, or osseous hardness, whether natural or preternatural: but most frequently it means the callus generated about the edges of a fracture, provided by nature to preserve the fractured bones, or divided parts.

CALODENDRUM, a genus of the class and order pentandria monogynia. The essential character is, calyx spreading, five-petalled; nect. five-leaved; capsule five-celled. There is one species, a native of the Cape.

CALOMEL. Chloride of mercury; frequently called mild muriate of mercury; and sometimes, but less properly, submuriate of mercury.

CALOPHYLLUM, in botany, a genus of the polyandria monogynia class of plants, the corolla consists of four roundish, hollow, patent petals, and is larger than the cup; the fruit is a large globose drupe. There are two species.

CALORIC. This name is applied to fire or the substance which produces the sensation we call heat, but never to the sensation itself, or the effect produced by fire. Animal heat is preserved chiefly by the inspiration of atmospheric air. If the hand be put upon a hot body, part of the caloric leaves the hot body and enters the hand; this produces the sensation of *heat*. On the contrary, if the hand be put upon a cold body, part of the caloric contained in the hand, leaves the hand to unite with the cold body; this produces the sensation of *cold*. Caloric comes to us from the sun, at the rate of 200,000 miles in a second of time. Caloric may be procured by combustion, percussion, friction, the mixture of different substances, and by means of electricity and galvanism.

In a latent state, caloric exists in all substances with which we are acquainted; but it combines with different substances in very different proportions. The reader will find an able and highly interesting article on this subject in Dr. Ure's Chemical Dictionary.

CALORIMETER, in chemistry, an instrument contrived by Lavoisier and La Place for measuring the comparative quantities of caloric in bodies.

CALVARY, in heraldry, a cross so called, because it resembles the cross on which our Saviour suffered. It is always set upon steps.

CALUMET, a kind of pipe used by the American Indians as the ensign of peace, and for religious fumigations. It is made of red, black, or white marble; the head resembles our tobacco-pipes, but is larger, and is fixed on a hollow reed, to hold it for smoking: they adorn it with rounds of feathers and locks of hair, or porcupines' quills, and in it they smoke in honour of the sun, especially if they want fair weather or rain. This pipe is a pass and safe conduct amongst all the allies of the nation which has it given: in all embassies the ambassador carries it as an emblem of peace, and it always meets with a profound regard.

CALX properly signifies lime, but was formerly used by chemists for a fine powder remaining after the calcination of metals and other mineral substances.

CALYCANTHUS, a genus of the polygynia order and icosandria class of plants, in the natural method ranking among the dubious order. Calyx, monophyllous, pitcher form, squarrose, with small coloured leaves; the

corolla consists of the leaves on the calyx; the styles numerous, each having a glandular stigma, seeds many, each with a hair within a succulent calyx. There are two species, 1. Calycanthus floridus or Carolina all-spice tree. 2. Calycanthus præcox, the first is cultivated with us, but the other not.

CALYPTRANTHES, a genus of the icosandria monogynia class and order. The essential character is, calyx superior, truncate, covered with a veil-shaped rib; corolla none; berry one-celled, one to four-seeded. There are six species, trees and shrubs of the West Indies.

CALYX, among botanists, a general term expressing the cup of a flower, or that part of a plant which surrounds and supports the other parts of the flower. See BOTANY.

CAMAX, in botany, a genus of the class and order pentandria monogynia. The essential character is, corolla wheel-shaped; fila-

CAMBLET, or CAMLET, a plain stuff composed of a warp and woof, which is manufactured in a loom. There are camblets of several sorts: some of goats' hair, both in the warp and woof; others, in which the warp is of hair, and the woof half hair and half silk.

CAMELLIA, in botany, a genus of the monadelphia polyandria class, and in the natural method ranking under the 37th order, columniferæ. The calyx is imbricated and polyphyllous, with the interior leaves larger than the exterior. There are three species, natives of China and Japan.

CAMELEOPARDALIS, the *cameleopard, giraffe*, in natural history, a genus of the mammalia and order pecora. The generic character is, horns covered with a bristly skin, bony and permanent; in the lower jaw eight teeth in front, and on each side the exterior tooth deeply bilobate. There is but one species; viz. the giraffe, which, when, fully grown, has been known to attain the extraordinary height among quadrupeds of seventeen feet. Its head is small; its aspect gentle; its fore parts are much higher than those behind; its colours arranged so as particularly to please the eye; and its form, notwithstanding the very great length of the neck, and a general singularity, possesses great beauty and elegance. It is a native of several parts of Africa, living in forests, principally upon the foliage of trees.

CAMELOPARDALIS, in astronomy, a constellation of the northern hemisphere, consisting of 32 stars, situated between Cepheus, Cassiopeia, Perseus, the two Bears, and Draco.

CAMELUS, CAMEL, a genus of quadrupeds of the order pecora. The generic character is, horns none; front teeth in the lower jaw six, somewhat thin and broad; canine teeth distant, in the upper jaw three, in the lower two; upper lip divided. There are seven species. 1. C. dromedarius, Arabian camel, or dromedary; is found in the warmer parts of Asia, and in the upper regions of Africa.

The general height of the Arabian camel, measured from the top of the dorsal bunch to the ground, is about six feet and a half; but from the top of the head, when the animal elevates it, not much less than nine feet: the head is small, the neck long, the body of a meagre shape; the legs slender, and the tail reaches to the joints of the hind legs; the feet are large, and are hoofed in a peculiar style, the under part being covered with a strong tough skin, which enables the animal to travel with ease in sandy and stony places. On each leg are six callosities. On the lower part of the breast is also a large tubercle, which is gradually increased by the constant habit which the animal has of resting upon it in lying down.

The general colour of the camel is an uniform dusky brown. Its hair is fine and soft, and serves for the basis of several kinds of stuffs.

2. C. Bactrianus, Bactrian camel, in its general appearance much resembles the Arabian, differing only in having two bunches on the back instead of one.

3. Camelus glama, or Peruvian sheep, is a native of South America, where it inhabits the

of a stag; measuring about four feet and a half in height to the top of the shoulders, and about six feet in length from nose to tail. Its general colour is a light ferruginous brown.

4. Camelus vicuna. The vicuna bears a general resemblance to the glama; but is of a lighter and more delicate aspect.

The vicuna affords the finest wool of any, and it is wrought into cloths of most exquisite silky softness and beauty, which are said to be too warm for common wear, unless made peculiarly thin.

5. Camelus paco. This species is said to be entirely confined to Peru, where the natives keep vast flocks of them for the sake of the wool. Those concretions, known by the name of bezoars, are often found in the stomach of this as well as of other species.

6. Camelus hunacus, or the guanaco, is a native of Peru. It is the largest of all the Peruvian animals of this kind, and is said sometimes to grow to the size of a horse. Its general colour is tawny above and white below.

7. Camelus arcuoanus. This species which inhabits Peru and Chili, is described as measuring about six feet in length, and about four in height. It is covered with woolly hair, and in its general appearance is not unlike a ram. This animal is employed by the inhabitants of Chili as a beast of burthen, as well as in ploughing.

CAMEO, in natural history, a genus of the semi-pellucid gems, approaching to the onyx structure, being composed of zones, and formed on a crystalline basis, but having their zones very broad and thick, and laid alternately one on another, with no common matter between them; usually less transparent, and more debased with earth than the onyxes.

CAMERA *Lucida*,* the name of an optical instrument invented by Dr. Hook, for the purpose of making the image of any object appear on the wall in a light room, either by day or night. The name is now given to an instrument recently invented by Dr. Wollaston, which is altogether different, both in its construction and use, from that of Dr. Hook. The use of this simple, but truly ingenious instrument, is for drawing objects in true perspec

tive, and for copying, reducing or enlarging other drawings.

CAMERA *Obscura*, in optics, a machine representing an artificial eye, wherein the images of external objects are distinctly exhibited, in their native colours, either invertedly or erect. For a description of this and the preceding instrument, see OPTICS.

CAMERARIA, a genus of the monogynia order and pentandria class of plants, ranking in the natural method under the 30th order, contortæ. There are two species, 1. Cameraria angustifolia, which grows to the height of eight feet. The flowers are produced at the ends of the branches. It is a native of Jamaica. 2. Cameraria latifolia, a native of Cuba. It rises to the height of 12 feet, dividing into several branches, with roundish pointed leaves placed opposite. The flowers are of a yellowish white, and grow in clusters at the end of the branches.

CAMP, the ground upon which an army pitch their tents. It is marked out by the quarter-master-general, who appoints every regiment their ground.

CAMPAIGN, in the art of war, denotes the space of time that an army keeps the field, or is encamped, in opposition to quarters.

CAMPANULA, in botany, a genus of the pentandria monogynia class and order. Natural order of campanaceæ. Essential character: corolla bell form, the bottom closed with stamineferous valves; stigma three-cleft; capsule inferior, gaping, with lateral pores. There are 78 species, most of them natives of our own country, well known in the gardens and fields.

CAMPHOR, is a white concrete crystalline substance, not brittle, but easily crumbled, having a peculiar consistence resembling that of spermaceti, but harder. It has a strong lively smell, and an acrid taste; is so volatile as totally to exhale when left exposed in a warm air; is light enough to swim on water; and is very inflammable, burning with a very white flame and smoke, without any residue.

Camphor is extracted from the roots, wood, and leaves of two species of laurus, the roots affording by far the greatest abundance. The method consists in distilling with water in large iron pots, serving as the body of a still, with earthen heads adapted, stuffed with straw, and provided with receivers. Most of the camphor becomes condensed in the solid form among the straw, and part comes over with the water.

The roots of zedoary, thyme, rosemary, sage, the inula hellenium, the anemony, the pasque flower or pulsatilla, and other vegetables, afford camphor by distillation.

CAMPHOROSMA, stinking ground pine; a genus of the tetrandria order in the monogynia class of plants, ranking in the natural method under the 12th order, holoraceæ. There are five species. Of these the principal is,

Camphorosma Monspeliensis, which grows by the road-side in Languedoc, and especially about Montpelier. It has been produced as a specific for the dropsy, and asthma.

CANAL, a kind of artificial river, made for the convenience of water carriage. See INLAND NAVIGATION.

CANARINA, a genus of the order monogynia, and hexandria class of plants. The calyx is six-leaved; corolla six-cleft, bell-form. There are two species.

CANARIUM, a genus of the diœcia order in the pentandria class of plants. It has male and female flowers; in both, the calyx has two leaves, and the corolla consists of three petals: the fruit is a drupa with a three-cornered nut. There is but one species.

CANCER, in astronomy, one of the 12 signs, represented on the globe in the form of a crab, and thus marked (♋) in books. It is the fourth constellation in the zodiac. It gives name to a quadrant of the ecliptic, viz.

CANCER, *tropic of*, in astronomy, a lesser circle of the sphere parallel to the equator, and passing through the beginning of the sign Cancer.

CANCER, in medicine, a roundish, unequal, hard, and livid tumour, generally seated in the glandulous part of the body.

CANCER, the *crab*, in natural history, a genus of insects of the order aptera. The generic character: eight legs in general, sometimes six or ten, besides two chelated arms; two eyes, distant, in general foot-stalked, elongated, and moveable: tail unarmed, and jointed. Animals of this genus at particular periods cast their shells, previously to which the limbs shrink, to facilitate their extrication. The loss of a limb, with other animals irreparable, is of little consequence to these, as a few weeks suffice to reproduce one: and in cases of bruise or mutilation, a consciousness of this eventual, and indeed speedy reproduction, induces them violently to rid themselves of the injured member, and to await in seclusion the formation of a complete substitute for it.

Some species which are unprovided by nature with any shelly covering, have recourse to such shells as they find best accommodated to their purpose, and in which their bodies are immersed, while their claws are protruded and unprotected. The correspondence of parts in both sides of almost all other animals is far from being always observable in these. The claspers on one side are often of extraordinary size, and on the other slender and small; and in some instances the large arm is obliged to be supported by the back of the animal, both while walking and at rest from its unwieldy and extravagant size. The genus comprehends an immense variety of species; but the chief division is into the Brachyouri and the Macrouri, or the short-tailed and the long-tailed: under the former of which the crab commonly used in this country for food is the principal. It is found chiefly on the rocky coasts. Among the Macrouri, the common lobster is the principal, and a well-known specimen. It inhabits in the clearest water, and at the base of rocks which project over the sea. It is extremely prolific, depositing about 12,000 eggs each time of laying. The warmth of summer is required for maturing them. The C. Norwegicus, or Norwegian crab, is naturally of a pale red colour, and variegated with yellow. It is longer, and more slender than the ordinary lobster.

CANCROMA, or *boat-bill*, in ornithology, a genus of birds belonging to the order of grallæ; the characters of which are: The bill is broad, with a keel along the middle; the nostrils are small, and lodged in a furrow; the tongue is small; and the toes are divided

These are two species: viz. Cancroma cancrophaga, or the brown boat-bill; and Cancroma cochlearia, the crested boat-bill.

CANDLE, a taper of tallow, wax, or spermaceti, the wick of which is commonly of several threads of cotton, twisted together.

A tallow-candle, to be good, must be half sheep's and half bullocks' tallow. The wick ought to be pure, sufficiently dry, and properly twisted, otherwise the candle will emit an unconstant vibratory flame, which is both prejudicial to the eyes and insufficient for the distinct illumination of objects.

There are two sorts of tallow-candles; the one dipped, the other moulded: the former are the common candles. The tallow is prepared by chopping the fat, and then boiling it in a copper; and when the tallow is extracted the remainder is subjected to the operation of a strong iron press, and the cake that is left after the tallow is expressed from it is called greaves: with this dogs are fed, and the greater part of the ducks that supply the London markets.

When the tallow is in proper order, the workman holds three of the broaches, with the cottons properly spread, between his fingers, and immerses the cotton into the vat containing the tallow: they are then hung on a frame and suffered to cool; and when cold they are dipped again, and so the process is continued till the candles are of the proper size.

The mould in which the moulded candles are cast, consists of a frame of wood, and several hollow metal cylinders, generally made of pewter, of the diameter and length of the candle wanted: at the extremity of these is the neck, which is a little cavity, pierced in the middle, with a hole large enough for the cotton to pass through. The cotton is introduced into the shaft of the mould by a wire being thrust through the aperture of the hook till it comes out of the neck: the other end of the cotton is so fastened as to keep it in a perpendicular situation, and in the middle of the candle; the moulds are then filled with warm tallow, and left to cool.

To make wax-candles with the ladle.—The wicks being prepared, a dozen of them are tied by the neck, at equal distances, round an iron circle, suspended directly over a large bason of copper tinned, and full of melted wax: a large ladleful of this wax is poured gently on the tops of the wicks till the candle arrives at the intended size.

In making wax-candles by the hand, they begin to soften the wax by working it several times in hot water, in a narrow deep cauldron. A piece of the wax is then taken out, and disposed by little and little around the wick, which is hung on a hook; so that they begin with the large end, diminishing as they descend towards the neck.

The cylindrical wax candles are either made as the former, with a ladle, or drawn. Wax candles, or tapers drawn, are so called because they are actually drawn in the manner of wire, by means of two large rollers of wood turned by a handle, which pass the wick through melted wax contained in a brass bason, and at the same time through the holes of an instrument like that used for drawing wire, fastened on the side of the bason.

CANDLE, Sale or auction by inch of candle, is when a small piece of candle being lighted, the by-standers are allowed to bid for the merchandize that is selling: but the moment the candle is out, the commodity is adjudged to the last bidder.

CANDY, or *sugar-candy*, a preparation of sugar, made by melting and crystallizing it six or seven times over, to render it hard and transparent.

CANELLA, in botany, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is but one species, viz.

Canella alba. It grows usually about 20 feet high, and 8 or 10 inches in thickness, in most of the Bahama islands. The bark is a warm stomachic.

CANE, CANNA. See ARUNDO. It is also the name of a long measure, which differs according to the several countries where it is used.

At Naples, the cane is equal to 7 feet 3 inches English measure; the cane of Thoulouse, and the upper Languedoc, contains 5 feet 8⅔ inches; at Montpelier, Provence, Dauphine and the Lower Languedoc, to 6 English feet 5½ inches.

CANES *venatici*, in astronomy, the greyhounds, two new constellations between the tail of the Great Bear and Bootes's arms, above the Coma Berenices. They comprehend 23 stars. In the British Catalogue they are 25.

CANINE *teeth*, in anatomy, are two sharp-edged teeth in each jaw, one on each side, placed between the incisores and molares.

CANIS, *dog*, in zoology, the name of a comprehensive genus of quadrupeds, of the order of feræ. The generic character is cutting teeth in the upper jaw six; the lateral ones longer, distant; the intermediate ones lobated. In the lower jaw six; the lateral ones lobated. Canine teeth solitary, incurvated. Grinders six or seven. There are 24 species.

1st. Canis familiaris, or common dog. The real origin of this species is in a state of uncertainty: wild dogs appear to be found in great troops in Congo, lower Æthiopia, and towards the Cape of Good Hope. They are said to be red-haired, with slender bodies and turned up tails, like greyhounds.

It is not, however, allowed that these wild dogs constitute the real species in a state of nature, but that they are the descendants of dogs once domesticated, and which have relapsed into a state resembling that of primitive wildness.

That which is supposed by Buffon to approach most nearly to the original animal, is known by the name of the shepherd's dog.

The dingo, or New Holland dog, approaches in appearance to the largest kind of shepherd's dog. This dog is capable of barking, though not so readily as the European dogs: it is extremely fierce, and has the same snarling and howling voice as the larger dogs in general.

The Pomeranian dog is distinguished by upright ears, long hair on the head, and an extremely curved tail, so as to form almost a circle. This dog is generally of a white colour.

The Siberian dog is nearly allied to the preceding, and may be subdivided into several races, differing as to strength and size.

The Iceland dog seems to differ but slightly from the preceding kind. It has a short muzzle, upright ears, and is covered with long rough hair.

The water-dog is distinguished by its curly hair, like wool. It is remarkable for its great attachment to the water, swims with great ease, and is used in hunting aquatic birds. Its feet approach more to a webbed form than those of most other dogs.

The great water spaniel is also distinguished in a similar manner by its curled hair, and its propensity to the water.

The Newfoundland dog is large, and from its strength and docility, is one of those which are best calculated for the security of a house. This animal is remarkably fond of plunging into the water.

King Charles's dog is one of the most elegant varieties of the dog, and it is recorded that King Charles the Second hardly ever walked out without being attended by some of this breed. It is in some degree allied to the small water spaniel, and is generally black, with the roof of the mouth of the same colour.

The Maltese dog is also a very small kind of spaniel, generally of a white colour.

The hound admits of some varieties. The old English hound is distinguished by its great size and strength; and its power of smelling.

The blood hound is a very large dog, taller and more beautifully formed than the old English hound, and superior to most others in speed, strength, and sagacity.

The pointer is employed principally in finding partridges and other game.

The Dalmatian, or coach dog, is an animal of great beauty. Its native country seems uncertain. It is white and beautifully marked with numerous black spots.

The Irish greyhound is the largest of all the dog kind, as well as the most beautiful and majestic in its appearance. It is only to be found in Ireland, and even there is become extremely rare.

The common greyhound is remarkable for the slenderness of its shape, the length of its snout, and the extreme swiftness of its course. The greyhound wants the faculty of quick scent, and follows his prey merely by the eye. The Italian greyhound is a small and beautiful variety of the preceding.

The naked dog is naturally divested of hair, and is supposed to have originated in some warm climate.

The mastiff is of a very strong and thick form, with a large head, a bold countenance, and large lips hanging down on each side.

The bull dog resembles the mastiff, but is smaller, with a flatter snout, and a greater ferocity of aspect. The bull dog is remarkable for the undaunted and savage pertinacity with which it provokes and continues the

every pack of hounds, and is very expert in forcing foxes or other game out of their coverts.

The turnspit is a breed very much on the decline in England, though still used in some other countries. It is a long-bodied, short-legged dog, with crooked or bowed knees and is commonly of a dusky grey, spotted with black. To these we may add the alco, or Peruvian dog, and several mixed breeds from the above.

2d. Canis lupus, or wolf, is distinguished from the dog by his superior size, stronger limbs, more muscular body, and greater breadth of the upper part of the face, while the whole form of it is longer: the tail has an inward direction; it is rather long and bushy. The wolf is a native of almost all the temperate and cold regions of the globe. It is found in most countries of Europe, but has been extirpated from our own island, as well as from Ireland.

The general colour of the wolf is a pale grey, with a cast of yellow.

The wolf is sometimes affected with madness, attended with similar appearances to those exhibited in that state by the dog, and productive of the same symptoms in consequence of its bite; this disease is said to happen to them in the depth of winter, and therefore, can never be attributed to the rage of the dog days.

3d. Canis Mexicanus, or Mexican wolf. In its general appearance it resembles the common wolf, but has a head twice as large, a thicker neck, and a less bushy tail: the colour of the body is cinereous, marked with some yellow spots. Above the mouth are several bristles as large, but not so stiff, as those of the hedgehog.

4th. Canis lycaon, or black wolf, is found both in Europe and America, as well as in some parts of Asia.

In America it is chiefly found in Canada, and in Europe only in the more northern regions.

5th. Canis hyæna, is a native of Asia and Africa. Its general size is that of a large dog. Its colour is a pale greyish-brown accompanied by a tawny cast, and the whole body is marked by several black transverse bands running from the back downwards. Hyænas generaly inhabit caverns and rocky places: they prowl about chiefly by night, and feed on the remains of dead animals as well as on living prey. They sometimes assemble in troops, and follow the movements of an army, in the hope of feasting on the slaughtered bodies.

6th. Canis crocuta, or spotted hyæna, resembles the former, but it is superior in size, and is marked all over with black spots. It is an African animal, and is found in Guinea, Æthiopia, and about the Cape of Good Hope.

7th. Canis aureus, or jackal, is a native of Asia and Africa, and appears to be most common in Barbary. It is about the size of a dog, and of a pale orange-yellow, with darker shades about the back and legs. The jackal resides in rocky places, and makes its principal excursions during the night. These animals go in

the lion, attending to the clamour, is said to follow till the jackals have hunted down the prey, and, having satiated himself, leaves only the remains to the jackals.

8th. Canis mesomelas, or Cape jackal, is common about the Cape of Good Hope, and is by some confounded with the jackal, to which, indeed, it seems to be very nearly allied.

9th. Canis Barbarus, Barbary jackal, has a long slender nose, sharp upright ears, and a long bushy tail. Its colour is a very pale brown. It is of the size of the common fox, but the limbs are shorter, and the nose more slender.

10th. Canis Ceilonicus, Ceylonese dog, is a native of Ceylon, but no particulars relative to its manners or history are known. It is a little larger than a common domestic cat. The claws of this animal resemble those of a cat more than of a dog, though not so long and slight in proportion.

11th. Canis vulpes, or fox, appears to be pretty generally diffused throughout all the northern and temperate parts of the globe; occuring with numerous varieties of colour and gradations of size, in most parts of Europe, the north of Asia, and America.

12th. Canis alopex, brant fox, is less than the common fox, and has a thicker and darker fur.

13th. Canis corsac, or corsac fox. The colour of this species is, in summer, a clear yellow-ferruginous; in winter mixed or shaded with grey.

14th. Canis Karagan, or Karagan fox. This is a small species, very common in almost all parts of the Kirghisian deserts and Great Tartary. Its general colour is grey; the head yellow, and the belly white.

15th. Canis cinero-argenteus, or fulvous-necked fox, inhabits North America. The crown of the head, neck, and back, are grey, mixed with black and white. In size this species is inferior to the common fox.

16th. Canis Virginianus, or Virginian fox, resembles the common fox in shape; has a sharp nose, long, sharp, upright ears, long legs, and a bushy tail: its colour is a whitish grey, with a cast of red about the ears. It is said never to burrow under ground, but to inhabit hollow trees: it is easily tamed, and is said to prey chiefly on poultry, birds, &c.

17th. Canis argentatus, silvery fox, resembles the common fox. It is an inhabitant of the forests of Louisiana, and preys on game.

18th. Canis lagopus, arctic fox, is inferior in size to the common fox. Its colour is a bluish-grey, which sometimes changes to perfect white. They inhabit Spitsbergen, Greenland, and Iceland. They swim well, and often cross from island to island in search of prey.

19th. Canis culpæus, Chili fox, is supposed to be a variety of the antarctic fox. It inhabits the open countries of Chili, in which it forms its burrows.

20th. Canis thous, or Surinam dog, is of a grey colour and entirely white beneath; its size is that of a large cat.

21st. Canis Bengalensis, Bengal fox, is scarcely half the size of the European fox. The face is cinereous, the body pale-brown. It is said to feed chiefly on roots and berries.

22nd Canis fuliginosus, sooty fox, in size and habit resembles the arctic fox, but is a distinct species. It is numerous in Iceland.

23d. Canis antarcticus, antarctic fox, is superior in size to the arctic fox. It is a native of the Falkland isles, and lives on water fowl.

24th. Canis zerda, the Fennec, or zerda, is a beautiful animal, and is principally found in Arabia. Its general length is about ten inches, and its colour yellowish-white. The ears are internally of a bright rose-colour, edged with white, and the tip of the tail is black. It inhabits the vast deserts of Zaara; it burrows in sandy ground, and is so exceedingly swift that it is very rarely taken alive. It feeds on insects, especially locusts, and barks like a dog.

Canis *major*, in astronomy, a constellation of the southern hemisphere, consisting of 28 stars, according to Ptolemy; of 13, according to Tycho; and 32 in the Britannic Catalogue.

Canis *minor*, **Caniculus**, or **Canicula**, in astronomy, a constellation of the northern hemisphere. In Ptolemy's Catalogue, the canis minor comprehends two stars; in that of Tycho, five; and in the Britannic Catalogue, 15.

CANKER, a disease incident to trees, proceeding chiefly from the nature of the soil. It makes the bark rot and fall.

CANNA, in botany, *Indian flowering reed*, or *Indian shot*, a genus of the monandria monogynia class and order. Natural order of Scitamineæ. Essential character: corolla six-parted, erect; lip two-parted, revolute; style lanceolate, growing to the corolla; calyx three-leaved. There are five species, most of them natives of America.

CANNABIS, in botany, *English hemp*, a genus of the diœcia pentandria class and order. Natural order of scabridæ. Essential character: male, calyx five-parted; corolla none; female, calyx one-leafed, entire, gaping on one side; corolla none; styles two; nut bivalve, within the closed calyx. There is but one species, viz. C. sativa. The uses of hemp are well known, as well as its great importance to the navy for sails and cordage. Exceedingly good huckaback is made from it for towels and common table-cloths. English hemp, properly manufactured, stands unrivalled in its strength, and is superior to the Russian.

CANNON. See Gunnery.

CANOE, a small boat, made of the trunk of a tree, bored hollow; and sometimes also of pieces of bark, sewed together. It is used by the natives of America to go a-fishing in the sea, or upon some other expedition, either by sea, or upon the rivers and lakes.

CANON, in mathematics is a rule to solve all things of the same nature with the thing proposed.

The tables of logarithms, artificial sines, and tangents, are called likewise by the name of canon.

CANTATA, in music, a song or composition, intermixed with recitatives, airs, and different movements, chiefly intended for a single voice, with a thorough bass, though sometimes for other instruments.

CANTEEN, a small vessel made of tin-plate or wood, in which soldiers, when on

their march, or in the field, carry their liquor They are cylindrical, like barrels 7½ inches in diameter, and about four inches deep, holding three pints.

CANTHARIS, a genus of coleopterous insects, with setaceous antennæ, the exterior wings of which are flexile, the thorax flatted, and the sides of the abdomen plicated. Linnæus enumerates 27 species of the cantharis.

CANTO, in music, the treble or at least the higher part of a piece.

CANTONED, in architecture, is when the corner of a building is adorned with a pilaster, and angular column, rustic quoins, or any thing that projects from the wall.

Cantoned, or **Cantonized**, *cantonee*, in heraldry, the position of such things as are borne with a cross, &c. between.

CAOUTCHOUC. This substance, sometimes termed, though improperly, *elastic gum*, and vulgarly, from its common application to rub out pencil marks on paper, *Indian rubber*, is obtained from the milky juice of different plants in hot countries. The principal of these are the Jatropha elastica, and Urceola elastica. To give this substance any particular form, the juice is applied in successive coatings on a mould of clay, and dried by the fire or in the sun; and when of a sufficient thickness, the mould is crushed, and the pieces are shaken out. The most remarkable property of this substance is its elasticity: when warmed, as by immersion in hot water, slips of it may be drawn out to seven or eight times their original length, and will return to their former dimensions nearly. Cold renders it stiff and rigid, but warmth restores its original elasticity. Exposed to the fire it softens, swells up, and burns with a bright flame. Oil of turpentine softens it, and forms a pasty mass, that may be spread as a varnish, but is very long in drying. A solution of caoutchouc in five times its weight of oil of turpentine, and this solution dissolved in eight times its weight of drying linseed oil by boiling, is said to form the varnish of air-balloons.

CAP, in a ship, a square piece of timber put over the head or upper end of any mast, having a round hole to receive the mast. By means of these caps the top-masts and top-gallant-masts are kept steady and firm in the tressel-trees where their feet stand.

Cap *of a gun*, a piece of lead which is put over the touch-hole of a gun to keep the priming from being wasted or spoiled.

CAPELLA, in astronomy, a bright fixed star of the first magnitude, in the left shoulder of the constellation Auriga. Its longitude is 17° 31′ 41″, its latitude 22° 51′ 47″.

CAPER. See Capparis.

CAPIAS, is a writ of two sorts, one whereof is called *capias ad respondendum*, before judgment, where an original is sued out, &c. to take the defendant and make him answer the plaintiff: and the other a writ of execution, after judgment, being of divers kinds.

CAPILLARY *vessels*, in anatomy, the smallest and extreme parts of the veins and arteries.

CAPITAL, the head, chief, or principal of a thing. Thus,

Capital, in geography, denotes the principal city of a kingdom, province, or state; as London is the capital of Britain.

Capital, in architecture, the uppermost part of a column or pilaster, serving as the head or crowning, and placed immediately over the shaft, and under the entablature.

CAPITULATION, in military affairs, a treaty made between the garrison or inhabitants of a place besieged, and the besiegers, for the delivering up the place on certain conditions.

CAPPARIS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 25th order, putamineæ. There are 26 species, of which the principal is,

Capparis spinosa, or common caper, a low shrub, generally growing out of the joints of old walls or fisures of rocks in the warm parts of Europe. This plant is with great difficulty preserved in England. The pickle made from its berry is well known.

CAPRA, the goat-kind, in zoology, a genus of quadrupeds, of the order of pecora. The generic character is, horns hollow, turning upwards and backwards, compressed, rough, almost close at their base; front teeth in the lower jaw eight; canine-teeth, or tusks, none; chin bearded in the male. There are nine species and varieties.

1. Capra Ibex. It is found in several parts of Europe and Asia, and inhabits the Carpathian and Pyrenæan mountains, and various parts of the Alps.

It is an animal of great strength and agility, and is considerably larger than the domestic goat. Its colour is a greyish brown.

2. Capra Ægagrus, or Caucasan ibex, supposed to be the stock or origin of the domestic goat, is considerably superior to that animal in size, and its form in some degree resembles that of a stag. Its general colour is brown or grey, and the forehead is nearly black, which colour is continued down the back in the form of a stripe: the chin is furnished with a large brownish beard. and the horns, which are very large, and bend considerably backwards. The female is destitute both of horns and beard.

3. Capra Hircus, or common goat, is found in almost every part of the globe.

The colour of the domestic goat is various, being either black, brown, white, or spotted. The flesh is used as food by the inhabitants of Wales. The skin of the goat is peculiarly well adapted for the glove-manufactory, especially that of the kid.

The following are some of the varieties of the domestic goat.

1. Capra mambrica, or Syrian goat, is distinguished by the great length of the ears, which are pendulous. 2. Capra Angorensis, Angora goat, is generally of a milk-white colour, short-legged, with black, spreading, spirally twisted horns, and with the hair on the whole body disposed in long pendant spiral ringlets. It is from the hair of this animal that the finest camlets, &c. are prepared. 3. Capra depressa, or African goat, is a dwarf variety, found in some parts of Africa. 4. Capra reversa, or Whidaw goat. This is also a dwarf variety, found in Africa, where its flesh is considered as an excellent food.

5. Long-horned Whidaw goat. 6. Capricorn goat.

CAPRARIA, SWEET-WEED, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There are five species.

CAPRICORN, in astronomy, one of the twelve signs of the zodiac, represented in globes in the form of a goat, and characterized by this mark ♑.

Tropic of CAPRICORN, a lesser circle of the sphere, which is parallel to the equinoctial, and at 23° 30′ distance from it southwards.

CAPRIMULGUS, GOAT-SUCKER, a genus of birds belonging to the order passeres. There are two species: 1. The Europæus, with the tubes of the nostrils hardly visible, which feeds on moths, gnats, &c. It appears in May, and leaves us in August. 2. The Americanus, a night bird, found in America.

CAPSICUM, in botany, GUINEA PEPPER, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 28th order, luridæ. The corolla is verticillated, and the fruit is a berry. There are five species; the principal are:

1. Capsicum annum, the common long-podded capsicum, commonly cultivated in the gardens. Of this there is one variety with red and another with yellow fruit.

2. Capsicum baccatum, bird pepper, rises with a shrubby stalk four or five feet high the fruit grows at the division of the branches, standing erect, these are small, oval, and of a bright red. This is the Cayenne pepper.

3. Capsicum grossum, the bell pepper. The fruit of this is red, and is the only kind proper for pickling.

CAPSTAN, or MAIN-CAPSTAN, in a ship, a large piece of timber resembling a windlass, placed behind the main-mast, formed into several squares with holes in them to admit bars. Its use is to weigh the anchors, to hoist up or strike down top-masts, &c.

CAPSULE, among botanists, a species of pericarpium or seed-vessel.

CAPTION, in law, is where a commission is executed, and the commissioners subscribe their names to a certificate, declaring when and where the commission was executed.

CAPURA, a genus of the class and order hexandria monogynia. The essential charac- [illegible]

East Indies.

CAPUT *mortuum*. The inert residuum of a distillation, or sublimation. The term is nearly obsolete.

CARABINE, a fire-arm, shorter than a musket, carrying a ball of twenty-four in the pound.

CARABUS, a genus of insects of the beetle kind. There are 34 species, mostly distinguished by their colour. The most remarkable is the crepitans, or bombardier. It keeps itself concealed among stones, and makes but little use of its wings; when it is touched, it makes a noise resembling the discharge of a musket in miniature, during which a blue smoke may be perceived proceeding from it. It may be made to play off its artillery, by scratching its back with a needle. Its chief enemy is another species of the same genus, but four times larger. When pursued, the bombardier has recourse to stratagem, by lying down in the path of the large carabus, which advances to seize it; but, on the discharge of the artillery, suddenly draws back, and remains a while confused, during which the bombardier conceals himself in some crevice.

CARACT, CARAT, or CARRAT, the name of that weight which expresses the degree of fineness that gold is of. The mint-master or custom, has fixed the purity of gold at 24 caracts; though it is not possible so to purify and refine that metal, but it will want still about one fourth part of a caract in absolute purity and perfection. The caract is divided into degrees to distinguish the greater or lesser quantity of alloy in gold.

It is also a certain weight which goldsmiths and jewellers use with which to weigh precious stones and pearls.

CARAVAN, in the East, signifies a company or assembly of travellers and pilgrims, and more particularly of merchants, who march in a body through the deserts, and other places, which are infested with Arabs or robbers.

CARAVANSERA, a large public building, or inn, appointed for receiving and lodging the caravans. It is commonly a large square building, in the middle of which there is a very spacious court; and under the arches or piazzas that surround it there runs a bank, raised some feet above the ground, where the merchants, and those who travel with them in any capacity, take up their lodgings, the beasts of burden being tied to the foot of the bank.

CARBON. When vegetable matter, particularly the more solid, as wood, is exposed to heat in close vessels, the volatile parts fly off, and leave behind a black porous substance, which is charcoal. If this be suffered to undergo combustion in contact with oxygen, or with atmospheric air, much the greater part of it will combine with the oxygen, and escape in the form of gas; leaving about a two-hundredth part, which consists chiefly of different saline and metallic substances. This pure inflammable part of the charcoal is what is commonly called *carbon;* and if the gas be received into proper vessels, the carbon will be found to have been converted by the oxygen into an acid, call the carbonic.

CARBONATES, compounds of carbonic acid with the salifiable bases. They are composed either of one prime of the acid and one of the base, or of two of the acid and one of the base. The former set of compounds is called carbonates, the latter bicarbonates.

Carbuncle, a gem highly prized by the ancients, probably the alamandine, a variety of noble garnet, it is of a deep red colour, with an admixture of scarlet.

CARBUNCLE, in heraldry, a bearing consisting of eight radii, four of which make a common cross, and the others a saltier.

CARCASE, a round vessel filled with combustible matters and pieces of gun or pistol barrels, loaded grenades, &c. Those for land service are large and thrown out of mortars.

CARD, among artificers, an instrument

consisting of a block of wood, beset with sharp teeth, serving to arrange the hairs of wool, flax, hemp, and the like: there are different kinds of them, as hand-cards, stock-cards, &c. but in the cotton and woollen manufactories the revolving cylindrical cards, or carding engines are in universal use.

CARDS, among gamesters, little pieces of fine thin pasteboard of an oblong figure, of several sizes, but most commonly in England three inches and a half long, and two and a half broad, on which are painted several points and figures. The moulds and blocks for making cards are exactly like those that were used for the first books: they lay a sheet of wet or moist paper on the block, which is first slightly done over with a sort of ink made with lamp-black diluted in water, and mixed with some starch to give it a body. They afterwards rub it off with a round list. The court-cards are coloured by means of several patterns, styled stane-files. These consist of papers cut through with a pen-knife, and in the apertures they apply severally the various colours, as red, black, &c. These patterns are painted with oil-colours, that the brushes may not wear them out; and when the pattern is laid on the paste-board, they slightly pass over it a brush full of colour, which, leaving it within the openings, forms the face or figure of the card.

CARDAMINE, *lady's smock*; a genus of the siliquosa order, in the tetradynamia class of plants. Of this there are 18 species; but the most remarkable is the cardamine pratensis, with a large purplish flower. It grows naturally in many parts of Britain, and is also called cuckow-flower.

CARDAMOM. See AMOMUM and MATERIA MEDICA.

CARDIA, or CARDIUM, in natural history, a genus of the vermes testaceæ, or shell-fish, the shell of which is formed of two ovals.

Of this genus there are 21 species, some nearly globose, others of a triangular figure, and others oblong. Under this genus are comprehended the cockles, ark-shells, &c. together with the pectini inauriti, or scallops without ears.

CARDIAC, an appellation given to such medicines as preserve or increase the strength of the heart.

CARDIALGIA, the *heartburn*, a disorder of the stomach attended with anxiety, a nausea, and often a reaching or actual vomiting.

CARDIOSPERMUM, *heart pea*, a genus of the trigynia order, in the octandria class of plants, and in the natural method ranking under the 39th order, trihilatæ. There are three species, natives of the East and West Indies.

CARDUUS, the *thistle*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. Of this genus there are 51 species, ten of which are natives of Britain.

CAREENING, in the sea language, the bringing a ship to lie down on one side, in order to trim and caulk the other side.

CAREX, the *sedge*, a genus of the monœcia triandria class and order of plants, and in the natural method ranking under the 3d order, calamariæ. The male flowers are digested into a long spike; the calyx is an oblong and imbricated amentum, consisting of acute, and lanceolated scales, each containing one flower: there is no corolla; the stamina are three erect setaceous filaments of the length of the calyx the antheræ are oblong and erect. In the female flowers the calyx is the same as in the male; there are no petals, but there is an inflated oblong nectarium; the germen is triangular, and is placed within the nectarium; the style is very short; the stigmata are two or three; long, crooked, pointed, and hoary. There are 97 species.

CARICA, the *papaw*, a genus of the decandria order and diœcia class of plants, in the natural method ranking under the 38th order, tricoccæ. The species are, 1. Carica papaya, which grows to the height of twenty feet and naked till near the top. The leaves are large and the flowers bell shaped and yellow. When these fall away the germen swells to a fruit of the size of a melon. This and all parts of the tree abound with a juice used to kill ring worms. The fruit is made into a pickle, and the buds of the female flowers into a sweetmeat. 2. Carica prosoposa has a branching stalk, and the flowers are of a rose-colour, the fruit is shaped like a pear and sweeter than the papaya. Both species are natives of the East and West Indi

CARICATURA, in painting, denotes the concealment of real beauties, and the exaggeration of blemishes, but still so as to preserve a resemblance of the object.

CARIES, in surgery, the corruption of a bone when it is depraved of its periosteum, and becomes fatty, yellow, brown, and at last black. See SURGERY.

CARINA, in botany, a keel, the name which Linnæus gives to the lower concave petal of a pea-bloom, or butterfly-shaped flower, from its supposed resemblance to the keel of a ship.

CARISSA, a genus of the monogynia order and pentandria class of plants; ranking in the natural method under the 30th order, contortæ. It has two berries, many-seeded. There are two species, both trees, and natives of Africa.

CARLINA, one of the species of the thistle whose roots are used in medicine. They have a strong smell, and a subacrid, bitterish, weakly aromatic taste. They are accounted warm alexipharmics and diaphoretics.

CARLINGS, in a ship, are two pieces of timber, lying fore and aft, from beam to beam, for the ledges to rest on to which the planks are fastened.

CARMINATIVES, in pharmacy, medicines used in colics, or other flatulent disorders, to dispel the wind. See PHARMACY.

CARMINE, a powder of a very beautiful red colour, bordering upon a purple, and used by painters in miniature, though but rarely, because of its great price.

CARNATION, in botany. See DIANTHUS.

CARNATION *colour*, among painters, is understood of all the parts of a picture, in general, which represent flesh, or which are naked and without drapery.

CARNELIAN. See CHALCEDONY.

CARNIVAL, or CARNAVAL, a time of rejoicing, a season of mirth, observed with great solemnity by the Italians, particularly at Venice, lasting from Twelfth-day till Lent.

CARNIVOROUS, an appellation given to animals which naturally feed on flesh, and thence called beasts or birds of prey.

CAROLINEA, a genus of the monadelphia polyandria class and order. The essential character is; monogynious, calyx simple, tubular, truncate; petal ensiform; pome five-grooved, two-celled. There are two species, natives of Guiana and Tobago.

CAROTIDS, in anatomy, two arteries of the neck, which convey the blood from the aorta to the brain.

CAROXYLON, a genus of the pentandria monogynia class and order: the essential character is; corolla five-petalled; nect. five-leaved, converging, inserted into the corolla; seed clothed. There is one species.

CARPESIUM, a genus of the syngenesia polygamia superflua class and order: the essential character is; calyx imbricate; down none; recept. naked. There are two species.

CARP. See CYPRINUS.

CARPENTRY, the art of cutting, framing, and joining large pieces of wood, for the uses of building. It is one of the arts subservient to architecture, and is divided into house-carpentry and ship-carpentry: the first is employed in raising, roofing, flooring of houses, &c. and the second in the building of ships, barges, &c. The rules in carpentry are much the same with those of joinery; the only difference is, that carpentry is used in the larger and coarser work, and joinery in the smaller and curious.

CARPET, a sort of stuff wrought with the needle, or on a loom. Persian and Turkish carpets are in most esteem, but we have excellents ones made in England, particularly at Kidderminster. In weaving carpets, the design or pattern is traced in its proper colours on cartoons tied before the workman, who thereby knows what colours and shades he is to use, and how many stitches of the same colour. In this he is assisted by squares, and these again are subdivided into partitions corresponding with the threads of the warp.

The great carpets are made on frames and rollers not unlike those for tapestry, and under similar guidance where the pattern is intricate Carpet-making supports many thousands of the industrious poor of this country; and, being almost wholly founded on the produce of our own island, is of great importance as a national benefit.

CARPINUS, the HORNBEAM, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. There are three species, viz.

1. Carpinus betulus, or common hornbeam; a deciduous tree, native of Europe and America.

2. Carpinus ostrya, the hop hornbeam, a native of Italy and Virginia.

3. Carpinus Virginiana, or flowering hornbeam.

CARPODETUS, a genus of the pentandria monogynia class and order. There is one species, a native of New Zealand.

CARRONADE, a short kind of ordnance, capable of carrying a large ball, and useful in close engagements at sea. It has its name from Carron, the place where this kind of ordnance was first made.

CARROT, DAUCUS, in botany. See DAUCUS.

CARTHAMUS, a genus of the order of polygamia æqualis, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. Of this genus there are 10 species; but the only remarkable one is—

Carthamus tinctorius, with a saffron coloured flower, a native of Egypt and some of the warm parts of Asia. It is cultivated in many parts of Europe, and in the Levant, whence great quantities of it are annually imported into Britain for dyeing and painting.

CARTILAGE, in anatomy, a body approaching much to the nature of bones, but lubricous, flexible, and elastic.

CARTILAGINOUS *fishes*, those with cartilaginous instead of bony skeletons: they constitute an order of fishes, answering to the Chondropterygious and Branchiostegious of Linnæus.

CARTON, or CARTOON, in painting, a design drawn on strong paper to be afterwards traced through, and transferred on the fresh plaster of a wall to be painted in fresco. The cartons at Hampton-court are designs of Raphael Urbino. They are seven in number, and form only a small part of the sacred historical designs, executed by this artist, while engaged in the chambers of the Vatican, under the auspices of popes Julius II. and Leo X.

CARTOUCHE, in architecture and sculpture, an ornament representing a scroll of paper.

CARTOUCHE, in the military art, a case of wood, holding about 400 musket balls, besides six or eight balls of iron, of a pound weight, to be fired out of a hobit, for the defence of a pass, &c.

CARTRIDGE, a case of pasteboard or parchment, holding the exact charge of a gun. Those for cannon and mortars are usually in cases of pasteboard or tin, sometimes of wood, half a foot long.

CARUM, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 25th order, umbellatæ. There is one species,—

Carum carui, the carraway of the shops, grows naturally in many places of Britain. It is a biennial plant; has a taper root like a parsnip, the taste of the seeds is strongly aromatic. It is much cultivated in Essex.

CARUS, in medicine, a sudden deprivation of sense and motion, affecting the whole body.

CARYATIDES, or CARIATES, in architecture, a kind or order of columns or pilasters under the figure of women dressed in long robes, after the manner of the Carian people, and serving instead of columns to support the entablement.

CARYOCAR, in botany, a genus of the tetragynia order, in the polyandria class of plants. The calyx is quinquepartite, the petals five, the styles most frequently four The fruit is a drupe, with nucleuses

and four furrows netted. There is one species.

CARYOPHYLLUS, the clove-tree, a *genus of the monogynia order, in the polyandria class of plants; and in the natural method ranking under the 19th order, hesperidæ. The corolla is tetrapetalous; the calyx tetraphyllous;* the berry monospermous, below the receptacle of the flower. Of this there is but one species, viz. the caryophyllous aromaticus, which is a native of the Molucca islands, particularly of Amboyna. It grows to the height of the laurel tree, and no verdure is ever seen under it. From the extremities of the branches grow quantities of flowers that are first white, then green, and at last red and hard, in which state they are properly cloves. When they become more dry they assume a yellow cast which ends in a dark brown. Cloves are stimulating aromatics, and yield abundance of oil.

CARYOTA in botany, a genus of the monoecia polyandria plants, classed by Linnæus under palmæ. There are two species.

CASE, among grammarians, implies the different inflexions or terminations of nouns, serving to express the different relations they bear to each other, and to the things they represent.

Case, among printers, denotes a sloping frame, divided into several compartments, each containing a number of types or letters of the same kind. From these the compositor takes out each letter as he wants it, to compose a page or form.

Case *of crown-glass* contains 12, 15, or 18 tables, according to the quality.

Case *of Newcastle green glass* contains 35 tables.

Case-*hardening*, a method of preparing iron, so as to render its outer surface hard, and capable of resisting any edged tool.

Case-*shot*, musket-balls, stones, old iron, &c. put into cases, and shot out of great guns.

CASHEW-*nut*. See Anacardium.

CASSIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is pentaphyllous; petals five; antheræ, upper, three barren; lower, three beaked: a leguminous plant. There are 51 species, of which C. diphylla, two-leaved cassia, is a shrub with a round stem; two semi-orbiculate, obtuse, striated leaves on a short petiole; stipules covering the whole branches. It is an annual. Native of the West Indies. Some of the cassias are, however, very tall trees, as the C. fistula, Alexandrian purging cassia, cassia stick tree, or pudding pipe tree, which is 50 feet high, with a large trunk dividing into many branches. Native of both Indies. C. senna, Egyptian cassia, or senna, the plant which produces the leaves commonly known in medicine by the name of senna, is an annual: it rises with an upright branching stalk, a foot high. It grows naturally in Persia, Syria, and Arabia, whence the leaves are brought, dried, and picked from the stalks, to Alexandria in Egypt, and being thence annually imported into Europe, it has the title Alexandrian added to it.

CASSIDA, a genus of insects, of the order of the coleoptera, with filiform or thread-like antennæ, thickest towards the extremities. Of this genus there are many species, some green, some grey, but most black; but all have been confounded by authors with the beetles *The larva casts its slough several times There is one species, of which the chrysalis resembles an armorial escutcheon. It is this* which produces our variegated cassida.

CASSINE, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 23d order, dumosæ. There are four species, all of them natives of warm climates.

CASSIOPEIA, a constellation in the northern hemisphere, situated between 45° and 75° N. declin. This constellation contains 55 stars, and passes vertically over the British Isles, and a large portion of Europe. In the year 1572, Tycho Brahe discovered, in this constellation, and very near the star κ, a new star which at first appeared larger than Jupiter, and more brilliant. The appearance of this star alarmed all the astronomers of the age, and was the cause of an astronomical controversy, in which the celebrated Beza was engaged. Some supposed it to be the star which appeared to the magi at the birth of Christ, and that it re-appeared to announce His second coming. After gradually decreasing for about 18 months, it totally disappeared.

CASSIUS, *precipitate of*, obtained from the muriate of gold by the means of tin. It is highly valued for the beauty of the colour which it gives to glass or enamel.

CASSOWARY. See Struthio.

CASSYTA, a genus of the monogynia order, in the enneandria class of plants. The corolla is in the form of a calyx, divided into six segments; the nectarium is composed of three truncated glands encompassing the germen; the interior filaments are glandular; and the drupe contains a single seed. There are two species.

CASTILLEIA, a genus of the didynamia angiospermia class and order. The essential character is calyx tubular, compressed; upper lip bifid, lower none; corolla, lower lip trifid, capsule two-celled. There are two species: natives of South America.

CASTING, among sculptors, is the taking of casts and impressions of figures, busts, medals, &c. The art of casting in plaster of Paris is extremely simple, and may be described in a few sentences. The first thing to be attended to is the taking of moulds from the objects that are to be represented in the casts. The mould should consist of as many pieces as the nature of the figure may require; these are to be made of fine plaster, for the purpose of taking the impression more effectually; and each part as it is made, must be neatly cut with a knife to the intended size, notched, so as to receive the plaster of which the adjoining piece is to be formed: and if necessary, a small piece of brass wire inserted in the middle of it in the form of a loop, by which, with a pair of pliers, the piece may be detached from the model, or from the cast, when, as is sometimes the case, it adheres too firmly to be detached by the hand. The smaller portions of a mould ought always to be surrounded with three, four, or more external parts, all joining by notches, and compactly bound together by a strong cord.

When a mould has been thus constructed, it should be allowed to dry gradually, and then nearly saturated with boiled linseed oil, applied to all its parts by means of a soft brush; and in a few days it may be used with safety, as it will then have acquired sufficient hardness. Before the intended cast be taken, the mould must be very carefully anointed with fine fresh hogs' lard, to prevent the adhesion of the cast: some advise the use of oil, but the oil is apt to sink into the mould and leave the surface dry.

To make the cast, let the plaster be dropped from the hand gradually into a bason containing a requisite quantity of water, stir it with a spoon until it acquires the consistence of cream; pour then a little of it into the mould, and move the mould in such a manner that the plaster shall touch every part of the interior surface, and pour out of the mould into the basin the portion of the plaster which remains and does not adhere to the surface. Repeat this process until the cast has become, by these successive coatings, of the desired thickness. The cast thus made must now be allowed to stand undisturbed until it be of sufficient hardness to admit of the mould being removed from it, which must be done with great care, particularly if the figure be complex.

Impressions of medals may be taken by first making a mould with sulphur, melted in an iron ladle, over a very slow fire; the medal being previously greased over with lard, and a rim of paper fastened round its edge, the sulphur is to be poured on it. In a few minutes it will set, and may be immediately detached from the medal, and is fit for use.

In making casts of this description the plaster should be laid on the mould first with a fine brush, to prevent air holes, and then worked to the requisite thickness by means of a thin flat knife, which is a much better method than putting a rim of paper round the mould and pouring on the plaster, as is commonly directed. To take off the cold effect which purely white plaster casts have, a little ochre is sometimes put into the water, which has a very pleasing effect: in the same way the cast may be rendered of a delicate flesh colour, or indeed of any colour required; or the figure may be made of one colour, and the ground of another.

CASTING, in a *Foundery* is the running of metals into any mould prepared for this purpose. See FOUNDERY.

CASTLE, a fortress or place rendered defensible by nature or by art. It frequently signifies the principal mansion of noblemen; and of this kind of buildings there were in the reign of Henry II. in England, no fewer than 115. Castles, according to Mr. Grose, are of no higher antiquity than the conquest.

CASTOR, the *beaver*, in zoology, a genus of the order of glires, of which the species are: 1. *Castor fiber*, or common beaver, is a native of the most northern parts of Europe, Asia, and North America. The tail is oval, and convex on the upper surface: and void of hair, except at the base. It has scaly divisions like the skin of a fish. The usual length of the beaver is three feet, and of the tail nearly one foot. The colour is a deep chesnut, but some are black. The hair is fine and glossy. The favourite resorts of the beavers are retired watery and woody places. In these situations they assemble in great numbers, living in a social state, and building their dwellings in an admirable manner. When they assemble, which is about June, or July, and have fixed on the place of their establishment, on the banks of some water, they begin by cutting down with their teeth the largest tree they can find, and always make it fall across the river. They then clear it from the branches while others cut down smaller trees, which they sink as piles, interweaving the branches with the larger stakes, and filling up the intervals with earth. The stakes paving the under part of the river, are placed perpendicularly, but the rest of the work slopes upwards to bear the pressure of the stream. On the great platform they construct their cabins, which have two openings, one for going on the land, and the other for throwing themselves into the water. The form of these cabins is oval, and from four to ten feet diameter. Some consist of three or four stories, and the walls are about two feet thick, raised perpendicularly on planks or stakes. They are very solid, and are plastered within and without. In the application of the mortar, beavers make use of their tails as trowels, and their feet for plastering. Each cabin has a magazine to hold bark and young wood, which is their favourite food; some villages consist of twenty or twenty-five cabins, but the usual number is twelve. The smallest cabins contain two, four, or six beavers, and some have as many as thirty. They have generally as many females as males. On the alarm of danger, they give each other warning by striking the water with their tail, the noise of which is heard at a considerable distance, and then each beaver seeks security, some by diving, others by concealing themselves within their habitations. The beaver often swims under the ice, and is then most easily taken, by watching the cabin and the hole where it is obliged to come up for air. Some beavers live solitarily in holes on the banks of rivers, but their fur is not so good as that of the others.

2. Castor huidobrius, or Chili beaver, is peculiar to South America, and lives chiefly on crabs and other fish. It is about three feet long, and very broad, with two sorts of hair, the shortest of which is highly esteemed, being as soft as velvet. It is a fierce animal, but does not construct a habitation like the common beaver, nor does it produce any castor.

CASTOR. A soft greyish-yellow or brown substance, found in four bags [illegible] inguinal region of the beaver. In a warm air it grows by degrees hard and brittle, and of a darker colour, especially when dried in chimneys, as is usually done.

CASUARINA, a genus of the monandria order, in the monoecia class of plants. There are five species, natives of New South Wales.

CAT. See FELIS.

CAT-*harpings*, in a ship, small ropes running in little blocks from one side of the shrouds, to the other, near the deck, to tighten the shrouds, for the security of the masts.

CAT-*heads*, two strong beams of timber projected almost horizontally over the ships' bows, on each side of the bowsprit. The cat-head

serves to suspend the anchor clear of the bow, when it is necessary to let it go: it is supported by a sort of knee, which is generally ornamented by sculpture.

CATACAUSTIC *curves*, in the higher geometry, that species of caustic curves which are formed by reflection.

The catacaustic of a circle is a cycloid, formed by the revolution of a circle along a circle. The caustic of the vulgar semi-cycloid, when the rays are parallel to the axis, is also a vulgar cycloid, described by the revolution of a circle upon the same base. The caustic of the logarithmic spiral is the same curve, only set in a different position.

CATACOMB, a grotto or subterraneous place for the burial of the dead.

The term is particularly used in Italy, for a vast assemblage of subterraneous sepulchres, three leagues from Rome, in the Via Appia, supposed to be the sepulchres of the ancients.

CATANANCHE, CANDIA LION'S FOOT, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; the calyx imbricated; the pappus furnished with awns by a caliculus of five stiff hairs. There are three species, of which the most remarkable is the catananche cerulea, a hardy, herbaceous, and ornamental plant for the flower-garden. There is a variety with double flowers.

CATAPLASM, an external topical medicine, of a soft consistence, known by the common name of poultice, and prepared of ingredients of different virtues, according to the intention of the physician.

CATARACT, a precipice in the channel of a river, caused by rocks, or other obstacles stopping the course of the stream, whence the water falls with a greater noise and impetuosity.

CATARACT. See SURGERY.

CATARRH, in medicine, a defluxion from the head upon the mouth and aspera arteria, and through them upon the lungs.

CATECHU, in chemistry, a substance obtained by decoction, and inspissation from the wood of the mimosa catechu, a native of India, is a very powerf[illegible]stringent, and contains a large proportion of tanning.

CATEGORY, in logic, a series or order of all the predicates or attributes contained under any genus.

Aristotle made ten categories, viz. quantity, quality, relation, action, passion, time, place, situation, and habit.

CATENARIA, in the higher geometry, the name of a curve line formed by a rope hanging freely from two points of suspension, whether the points be horizontal or not.

CATERPILLAR. See PAPILIO.

CATESBÆA, the *lily thorn*, a genus of the monogynia order and tetrandria class of plants: in the natural method ranking under the 28th order luridæ. There are two species. 1. Catesbæa spinosa, native of the island of Providence, and discovered by Mr. Catesby. It grows to the height of 10 or 12 feet and the flowers are of a yellow colour. 2 Catesbæa parviflora.

CATHARTICS, in medicine, are the same with what are commonly called purgatives See MEDICINE.

CATHETER, in surgery, a fistulous instrument, usually made of silver, to be introduced into the bladder, in order to search for the stone, or discharge the urine when suppressed. See SURGERY.

CATHETUS, in geometry, a line or radius falling perpendicularly on another line or surface: thus the catheti of a right angled triangle are the two sides that include the right angle.

CATOPTRICS, that part of optics that treats of reflex vision, and explains the laws and properties of reflection, chiefly founded upon this truth, that the angle of reflection is always equal to the angle of incidence; and from thence deducing the magnitudes, shapes, and situations of the appearances of objects seen by the reflection of polished surfaces, and particularly plane, spherical, conical, and cylindrical ones. See OPTICS.

CAVALRY, a body of soldiers that charge on horseback, and may properly be called the right arm of the army: they are of great service in disturbing the enemy by their frequent excursions, in intercepting convoys, and destroying the country. The cavalry is divided into squadrons, and encamp on the wings of the army.

CAVEAR, CAVEER, or CAVIAR, the spawn or hard roes of sturgeon, made into small cakes, salted and dried in the sun. This sort of food is in great repute throughout Muscovy.

CAVIA, a genus of the order of glires. The animals of the genus cavia live on vegetable substances, and inhabit excavations under ground, or beneath the roots of trees. The principal of the genus are,

1. Cavia cobaya, the variegated cavy, or Guinea pig. This little animal is very easily rendered tame, but is seldom observed to shew any attachment to its benefactors; and is not distinguished by any remarkable degree of docility: it is, however, cleanly, harmless, and of a timid disposition.

2. Cavia paca or spotted cavy, is a native of South America and inhabits holes near the banks of rivers. It resembles a pig, and has been called the hog rabbit. The South Americans prize it as an article of food. 3. Cavia capybara. This species was considered by Linnæus as a kind of hog, and called by him sus-hydrochæris. It grows to a large size and inhabits Brasil, where it feeds on sugar canes and fish. 4. Cavia caudati aguti. This species is common in Guiana, and is of the size of a rabbit, but its motion resembles that of a hare. It burrows in the woods, and sometimes lives in hollow trees, feeding on roots, fruits, &c. [illegible] Cavia aguti leprone, the leporine cavy, seems to be a variety of the preceding. It is a native of Surinam and is about the size of a hare. 6. Cavia acuschy is smaller than the aguti and of an olive colour. It is also a native of South America. 7. Cavia aperea, or rock cavy, is a native of Brazil and partakes of the qualities of the rabbit and the rat. The colour is that of the hare, and the belly is white.

CAUKING, or CAULKING OF A SHIP, is driving oakum, or the like, into all the seams of the planks of a ship, to prevent leaking and

keep out the water. After the seams are stopped they are done over with a mixture of tallow, pitch, and tar, as low as the ship draws water.

CAULICOLES, or CAULICOLI, are eight stalks, in the Corinthian capital, springing out from four greater or principal cauls, or stalks.

CAULIFEROUS, an appellation given to such plants as have a perfect caulis or stem.

CAULIFLOWERS. See BRASSICA.

CAUSTIC *(lunar.)* Fused nitrate of silver. See SILVER.

CAUSTICITY. All substances which have so strong a tendency to combine with the principles of organized substances as to destroy their texture, are said to be caustic. The chief of these are the concentrated acids, pure alkalis, and the metallic salts.

CAUSTIC *curve*, in the higher geometry, a curve formed by the concourse or coincidence of the rays of light, reflected from some other curve.

CAUTERY, a medicine for burning, eating, or corroding, any solid part of the body.

CAZEMATE, or CASEMATE, in fortification, a certain retired platform in the flank of a bastion, for the defence of the moat and face of the opposite bastion.

CEANOTHUS, NEW JERSEY TEA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 43d order, dumosæ. There are six species, of which the most remarkable is the ceanothus Americanus, a native of most parts of North America. In England this plant seldom rises more than three feet high. The flowers grow at the ends of the twigs in clusters.

CECROPIA, a genus of the diandria order, in the diœcia class of plants; and in the natural method ranking under the 53d order, scabridæ. There is one species, a tree of South America.

CEDAR. See JUNIPERUS, and PINUS.

CEDAR, *bastard.* See THEOBROMA.

CEDAR, *white.* See CUPRESSUS.

CEDRELA, a genus of the monogynia order, in the pentandria class of plants; and ranking, according to the natural method, under the 54th order, miscellaneæ. There is only one species, called Barbadoes bastard cedar.

CELASTRUS, the STAFF TREE, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 43d order, dumosæ. There are 22 species, two of which are inured to our climate, viz. 1. Celastrus bullatus, an uncertain deciduous shrub, a native of Virginia. It is about four feet high. The flowers are produced in July, at the ends of the branches, in loose spikes. They are of a white colour, and are succeeded by beautiful scarlet fruit. 2. Celastrus scandens, the flowers of which are green, and appear in June. The berries are red, and make a fine appearance in autumn.

CELERY. See APIUM.

CELOSIA, COCK'S-COMB, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 54th order, miscellaneæ. There are 14 species, the principal of which is, Celosia cristata, or common cock's-comb. The principal colours of its flowers are red, purple, yellow, and white; but there are some whose heads are variegated with two or three colours.

CELSIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 28th order, luridæ. The calyx is quinquepartite; the corolla wheel-shaped; the filaments bearded or woolly; the capsule bilocular. There are four species, natives of Armenia.

CELTIS, the LOTE, or *nettle-tree*, a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 53d order, scabridæ. It is an hermaphrodite plant. There are seven species, all of them deciduous. The most remarkable are 1. Celtis australis, the southern celtis, a native of Africa and the south of Europe. 2. Celtis occidentalis, the western celtis, a native of Virginia. 3. Celtis orientalis, the eastern celtis, a native of Armenia: it grows to about 12 feet. The flowers come out from the wings of the leaves; they are yellowish, appear early in the spring, and are succeeded by large yellow fruit.

CEMENT, a term used to denote whatever is employed to unite together things either of the same or of different kinds. In this sense it includes lutes, glues, and also solders of every kind; but it is more commonly employed to signify those of which the basis is an earth or earthy salt. The following are some of the cements used for particular purposes.

For Derbyshire Spar.

A cement for this purpose may be made with about seven or eight parts of resin and one of bees'-wax, melted together with a small quantity of plaster of Paris. When the ingredients are well mixed, and the whole is nearly cold, the mass should be well kneaded together. The pieces to be joined, must be heated until they will melt the cement, and then pressed together, some of the cement being previously interposed.

Jeweller's Cement.

For setting precious stones, when pieces are broken off by accident. In such cases the artist can frequently join the pieces so correctly that an inexperienced eye cannot discover the fracture; for this purpose a small piece of gum mastich is applied between the fragments which are previously heated sufficiently to melt the interposed gum.

A Cement for China, Glass, &c.

Take quick-lime and white of eggs, or old thick varnish; grind and temper them well together, and it is ready for use. Drying oil and white lead are also frequently used for cementing China and earthenware; but this cement requires a long time to dry. Where it is not necessary the vessel should endure heat or moisture, isinglass glue, with a little tripoli, or chalk, is better.

A Cement for Iron joints that will resist boiling water and steam.

Take two ounces of muriate of ammonia, one of flowers of sulphur, and sixteen of cast iron borings. Let them be well mixed in a mortar, and keep the powder dry. When the cement is wanted for use, take one part of

this mixture, twenty parts of clean iron borings, grind them together in a mortar, mix them with water to a proper consistence, and apply them between the joints. In a short time this cement unites with the iron into one mass.

Six parts of clay, one of iron filings, and linseed oil sufficient to form a thick paste, make a good cement for stopping cracks in iron boilers.

Temporary Cements for Glass-grinders, Lapidaries, &c.

Take pitch and boil it; add thereto, and keep stirring it all the while, fine sifted wood ashes, until you have it of a proper temper: a little tallow may be added, if necessary. For small work: to four ounces of resin add one-fourth of an ounce of bees-wax melted together; and four ounces of whiting, made previously red hot.

Shell-lac is a very strong cement for holding metals, glass, or precious stones, while cutting, turning, or grinding them. The metal, &c. should be warmed, to melt it.

A Cement for Electrical apparatus.

Five pounds of resin, one of bees-wax, one of red ochre, melted together, to which may be added about two table spoonsful of plaster of Paris, observing to mix the whole mass most intimately. A cheaper one for voltaic purposes is made of six pounds of resin, one of red ochre, half a pound of plaster of Paris, and a quarter of a pint of linseed oil. The ochre and plaster should be well dried, and added to the other ingredients when they are thoroughly melted.

Japanese Cement.

This elegant cement is made by mixing rice flour with cold water, and then gently boiling it. It is beautifully white, and when dry is almost transparent. This cement is used for joining the parts of all curious paper articles.

CENCHRUS, in botany, a genus of the polygamia monoecia class of plants. There are two flowers, the one male, the other hermaphrodite. There are 11 species.

CENSOR *of books*, a body of doctors or others established in divers countries to examine all books before they go to the press, and to see they contain nothing contrary to faith and good manners.

CENSUS, in Roman antiquity, an authentic declaration made before the censors, by the several subjects of the empire, of their respective names and places of abode.

CENT., in commerce, an abridgement of centum, is used to express the profit or loss arising from the sale of any commodity: thus we say, there is 10 *per cent.* profit, or 10 *per cent.* loss; which is $\frac{1}{10}$th profit, or $\frac{1}{10}$th loss, upon the sale of the whole.

CENTAUREA, a genus of the polygamia frustranea order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are 77 species, of which we shall only mention two, viz. 1. Centaurea cyanus, the bluebottle, grows commonly among corn. The juice of this flower stains linen of a beautiful blue colour, but it is not permanent without the addition of alum. 2. Centaurea glastifolia. The root of this species is an article in the materia medica.

CENTER, or CENTRE, a point equally distant from the extremities of a line, figure, or body.

CENTER *of a bastion*, a point in the middle of the gorge of a bastion, whence the capital line commences, and is generally at the angle of the inner polygon.

CENTER *of a conic section*, a point in which the diameters intersect each other.

CENTER *of a curve of the higher kind*, the point where two diameters concur. When all the diameters concur in the same point, Sir Isaac Newton calls it the general center.

CENTER *of a dial*, that point where the axis of the world intersects the plane of the dial; and also that point wherein all the hour-lines meet.

CENTER *of gravity*, in mechanics, that point about which all the parts of a body, in any situation, balance each other.

CENTER *of oscillation*, that point in a pendulum in which, if the weight of the several parts was collected, each vibration would be performed in the same time as when those weights are separate. The center of suspension is the point on which the pendulum hangs.

CENTER *of percussion*, in a moving body, that point wherein the percutient force is greatest.

CENTINEL or CENTRY, is a private soldier, from the guard posted upon any spot of ground, to stand and watch carefully for the security of the said guard, or of any body of troops, or post, and to prevent any surprise from the enemy.

CENTRAL *forces*, the powers which cause a moving body to tend towards, or recede from, the center of motion.

CENTRIFUGAL *force*, that by which all bodies that move round any other body, in a curve, endeavour to fly off from the axis of their motion in a tangent to the periphery of the curve, and that in every point of it.

CENTRIPETAL *force*, that force by which a body is everywhere impelled, or tends towards some point as a center; such are gravity, or that force whereby bodies tend towards the center of the earth; magnetical attraction, whereby the loadstone draws iron; and that force, whatever it be, whereby the planets are continually drawn back from right-lined motions, and made to move in curves.

CENTRISCUS, in ichthyology, a genus of fishes belonging to the order of amphibianantes. There are two species. 1. The scutatus, which has its back covered with a smooth bony shell, which ends in a sharp spine, under which is the tail, but the back fins are between the tail and the spine. It is a native of the East Indies. 2. The scolopax, has a rough scabro[illegible] body, and a straight extended tail. It has two belly-fins, with four rays each, and has no teeth. It is found in the Mediterranean.

CENTUNCULUS, a genus of plants called by some *anagallidiastrum*, and by others a species of *anagallis*. It belongs to the tetrandria monogynia class of plants; the flower is monopetalous, the tube globose, and the limb divided into four oval segments: the fruit is an unilocular capsule, containing several roundish seeds. There is one species, annual.

CENTURION, among the Romans, an

officer in the infantry, who commanded a century or a hundred men.

CEPHALANTHUS, a genus of the tetrandria monogynia class of plants: the corolla a single petal, the tube slender; the limb divided into four parts; the fruit an oblong capsule, containing only one cell; the seeds are numerous and oblong. There are five species, trees and shrubs of China.

CEPHALIC *medicines*, are remedies for disorders of the head.

CEPHALIC *vein*. See ANATOMY.

CERAMBYX, a genus of beetles, the characters of which are; the antennæ long and setaceous; the thorax oblong, rounded, and pointed at each extremity. Under this genus is comprehended the capricorn-beetle. There are 83 species.

CERASTIUM, MOUSE-EAR, a genus of the decandria pentagynia class of plants, the flower of which consists of five bifid petals; and its fruit is a very long unilocular pod, containing numerous roundish seeds. There are 18 species of this weed.

CERATE, in pharmacy, a medicine used externally in several diseases, especially those of the skin. It is generally of four sorts, the white, the yellow, the cicatrizing, and the mercurial cerate.

CERATOCARPUS, a genus of the monœcia monandria class of plants, having no petals, and a small, compressed, bicornate seed, not unlike that of bidens.

CERATONIA, the CAROB TREE, or *St. John's Bread*, a genus of the triœcia order, in the polygamia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is hermaphrodite and quinquepartite; there is no corolla; the stamina are five; the style is filiform; the legumen coriaceous and polyspermous. It is also diœcious, or male and female distinct on different plants. There is but one species, viz. Ceratonia siliqua, a native of Spain, of some parts of Italy, and the Levant. It is an evergreen, and grows in the hedges.

CERATOPHYLLUM, a genus of the polyandria order, in the monœcia class of plants, and in the natural method ranking under the 15th order, inundatæ. There are two species, of no note.

CERBERA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 30th order, contortæ. The fruit is a monospermous plum. Of five, the most remarkable species is, Cerbera atrouai, a native of the warm parts of America.

CERCELE, in heraldry. A cross cercele is a cross which, opening at the ends, turns round both ways like a ram's horn.

CERCIS, the JUDAS TREE, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. There are only two species, both deciduous. The most remarkable is, Cercis Canadensis, or Canadian cercis: it will grow to the height of twenty feet in some places. The flowers are often eaten in sallads, and afford an excellent pickle.

CEREBELLUM, in anatomy, the hinder part of the brain. See ANATOMY.

CEREBRUM. See ANATOMY.

CERINTHE, HONEY WORT, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. There are two species, natives of Germany, Italy, and the Alps. They are low annual plants, with purple, yellow, and red flowers.

CERIUM, a new metal obtained from a fossil found in Sweden, to which has been given the name of Cerite. This fossil occurs disseminated or massive; it is of a flesh red colour, more or less deep, with sometimes a shade of yellow: it is semi-transparent: its fresh fracture has considerable lustre. It strikes fire with steel with difficulty: is not attracted by the magnet: its specific gravity is from 4.7 to 4.9. Exposed to a strong heat it does not melt, but loses 5 or 6 per cent. of weight, becomes friable, and acquires a bright yellow colour.

CERTHIA, the creeper, or ox-eye, a genus of birds belonging to the order of picæ. There are 50 species, the principal of which are, 1. The familiaris, or common ox-eye, which is grey above and white below with brown wings, and white spots on the prime feathers. This bird is common in our island and runs with great facility on the bark of a tree. Its food is chiefly insects, the eggs, which are generally five, are ash-coloured. 2. The hook-billed green creeper is a native of the Sandwich islands. The inhabitants of which make use of its feathers to form their ornamental dresses 3. The pusila is of a brown colour with a gloss of copper, and white beneath. It is a native of the Cape of Good Hope, and fond of honey 4. The Loteni, or Loten's creeper, has the upper parts of a green gold colour. This elegant bird inhabits Ceylon and Madagascar 5. The cerulea or blue creeper, has the head of a fine blue, and on each side a stripe of black in which the eyes are seated; the rest of the body is a violet blue, except the chin and throat, which are black. Its nest resembles a retort and the neck is a foot long. 6. The sannio or mocking creeper, is about the size of a thrush. The head is inclined to a violet colour, and the general plumage is olive green. It is an inhabitant of New Zealand, it has the faculty of imitating the notes of other birds.

CERTIORARI, an original writ, issuing out of the court of chancery or the king's bench, directed to the inferior courts, commanding them to certify or to return the records of a cause depending before them, to the end the party may have the more sure and speedy justice before the king or such justices as he shall assign to determine the cause.

CERVICAL *nerves*, in anatomy, are eight pair of nerves, so called as having their origin in the neck.

CERUMEN, is a viscid yellow-coloured liquid secreted by the glands of the auditory canal, which gradually becomes concrete by exposure to the air. It has an orange-yellow colour and a bitter taste. When slightly heated upon paper, it melts, and stains the paper like an oil; at the same time it emits a slightly aromatic odour.

CERUSE, or CERUSS, white-lead, a sort of calx of lead, made by exposing plates of that metal to the vapour of vinegar

CERVUS, the STAG OR DEER-KIND, in zoology, a genus of quadrupeds of the order of the pecora. The generic character is: horns

solid, covered while young with a hairy skin, growing from the top, naked, annual, branched. Front teeth in the lower jaw, eight. Canine teeth, none; sometimes single in the upper jaw.

The following are the most remarkable species. 1. Cervus alces, or elk. This is the largest of the genus, and when full grown is about the size of a horse. The neck is short and thick; the head large, the horns spreading into a broad palmated form. It is an inoffensive animal and feeds on the boughs of trees. The female has no horns. In Europe the elk is chiefly found in Sweden, Norway, and Russia: and the largest are in Siberia. In America they are most common in Canada, where they are called moose-deer. 2. Cervus tarandus or reindeer, is an inhabitant of the northern regions, chiefly in Norway, Lapland, Greenland, and in Siberia. The height is about five feet, and the legs are shorter in proportion than those of the stag. The general colour is brown above, and white beneath; but, as it grows older, it becomes of a grey-white. The horns are long and slender, and they besides have a pair of brow antlers with tips which expand forwards. The Laplanders use this animal for various purposes. 3. Cervus elaphus or stag, is of an elegant figure. It varies in different climates both in size and colour; the general height is three feet and a half, and the colour a reddish brown. The usual number of branches in the horns of a well grown stag are six or seven. It generally casts or sheds its horns in March, and at the end of June they are full grown. 4. Cervus dama, or fallow deer, is smaller than the stag, and of a brown-bay colour and whitish beneath. 5. Cervus Virginianus, Virginian deer, is a native of North America, where it associates with its own tribe in great numbers. In size it resembles the fallow deer, and the colour is a light brown. 6. Cervus axis, or spotted axis, is a beautiful species, about the size of the fallow deer, and in colour a light rufous brown, marked with white spots. It is an eastern animal. 7. The middle axis; this appears to be only a variety of the preceding, and is in size between the spotted axis and the great axis. The colour is the same as the former, but without spots. It is a native of Ceylon, Borneo, Celebes, and Java. 8. Great axis. The existence of this variety is ascertained by a pair of horns in the British Museum, which measure two feet nine inches in length. It is supposed they were brought from Ceylon or Borneo. 9. Cervus pygargus, or tailless roe is a native of Russia and Siberia. It resembles the roebuck, but is larger, and, instead of a tail, has a broad cutaneous excrescence. 10. Cervus Mexicanus, or Mexican roe, is of a reddish colour spotted with white. 11. Cervus porcinius, or porcine deer, has slender horns, thirteen inches long: the height of the animal is two feet two inches; the body thick and the colour brown. 12. Cervus capreolus, or common roe, is of a reddish brown colour, three feet nine inches long, height 2 feet 7 inches, and the length of the horns six or eight inches. It is an inhabitant of Europe and Asia. 13. Cervus muntjac, or rib-faced deer, is a native of Java and Ceylon. It is less than the roebuck, and what principally distinguishes it is the appearance of three longitudinal subcutaneous ribs, extending from the horns to the eyes. A tusk depends from each side of the upper jaw. 14. Cervus guinensis, or grey deer, is of the size of a cat, and of a grey colour interspersed with black spots and lines. It is a native of Africa.

CESARE, among logicians, one of the modes of the second figure of syllogisms; the minor proposition of which is a universal affirmative, and the other two universal negatives.

CESTRUM, BASTARD JASMINE, a genus of the monogynia order, in the pentandria class of plants, in the natural method ranking under 28th order luridæ. The corolla is funnel-shaped; the stamina sending out a little tooth about the middle. There are six species, all natives of the warmest parts of America; so cannot be preserved in this country without artificial heat. They are flowering shrubs, rising in height from five to twelve feet, with flowers of a white, or pale yellow colour.

CETUS, in astronomy, a constellation of the southern hemisphere, comprehending twenty-two stars in Ptolemy's Catalogue, twenty-one in Tycho's, and in the Britannic Catalogue ninety-seven.

In this constellation is a variable star which appears and disappears periodically.

CETE, the seventh order in the mammalia class of animals; the characters of which are, breathing apertures on the head, tail horizontal, no claws. The animals of this order are all of the whale kind.

Cetaceous fish, like land-animals, breathe by means of lungs, being destitute of gills. This obliges them to rise frequently on the surface of the water to respire. They have the power of uttering sounds; and like land-animals, they suckle their young.

CHÆROPHYLLUM, CHERVIL: a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. There are ten species, two of which, called cow-weed and wild chervil, are weeds common in many places in Britain. The roots of the first are poisonous; the flowers afford an indifferent yellow dye; the leaves and stalks a beautiful green.

CHÆTODON, a genus of fishes belonging to the order of thoracici. The teeth are very numerous, thick, setaceous, and flexile; the rays of the gills are six. The back fin and the fin at the anus are fleshy and squamous. There are 23 species. The most remarkable is the acuminatus, or shooting fish, having a hollow cylindrical beak. It is a native of the East Indies

CHAFF, in agriculture, the husky substance of corn separated from the grain after threshing by the process of winnowing, it also signifies the rind of corn, and likewise straw cut small for the use of cattle.

CHAIN, a series of several rings, or links fitted into one another. Chains are made of various metals, sizes, and forms, for different uses. A gold chain is one of the badges of dignity of the Lord Mayor of London. It is also the badge of office of the Sheriff, but only while in office.

CHAINS, in a ship, those irons to which the shrouds of the masts are made fast to the chain walls.

Chain *shot*, two bullets with a chain between them. They are used at sea to shoot down yards or masts, and to cut the shrouds or rigging of a ship.

Chain *pump*. See Pump.

Chain, in surveying, a measure of length, made of a certain number of links of iron-wire, serving to take the distance between two or more places. Gunter's chain is of 100 such links, each measuring 7$\frac{92}{100}$ inches, and consequently equal to 66 feet, or four poles.

CHAINWORK, is a term applied to those articles of manufacture in which any kind of cordage or thread is linked together in the form of a chain. This term of course includes the process of tambouring; all the varieties of lace manufacture, hosiery, net-making, &c.

CHALCEDONY, in natural history, a genus of semi-pellucid gems, of an even texture, and a semi-opaque and crystalline basis, variegated with different colours. Of this genus there are a great many species, as the bluish white, the brownish black, and the yellow and red chalcedony.

This stone is found in many countries, particularly in Iceland and the Ferro islands. When striped white and black, or brown alternately, it is called *onyx;* when white and grey, *chalcedonix.*

CHALDRON, a dry measure, consisting of thirty-six bushels, heaped up, but on shipboard, twenty-one chaldron of coals are allowed to the score. The chaldron should weigh two thousand pounds.

CHALK. A very common species of calcareous earth, of an opaque white colour, very soft, and without the least appearance of a polish in its fracture. It contains a little siliceous earth, and about two per cent. of clay. Some specimens, and perhaps most, contain a little iron.

Chalk (*black*). Drawing slate. The colour of this mineral is greyish or bluish-black. Massive. The principal fracture is glimmering and slaty, the cross fracture dull, and fine earthy. It is in opaque, tabular fragments, stains paper black, streak glistening, and the same colour as the surface; easily cut and broken.

CHALLENGE, in law, is an exception made by the party put on his trial to jurors, either in civil or criminal causes. In cases of treason, the prisoner may challenge to the number of twenty-five, but in murder and other felonies only twenty.

CHALYBEATE, a term used to denote mineral waters which are impregnated with iron.

CHAMÆROPS, the dwarf palm, or little palmetto, in botany, a genus of the natural order of palmæ. Hermaphrodite calyx tripartite; corolla tripetalous: stamina six; pistils three, and three monospermous plums. The male is a distinct plant, and also the hermaphrodite. Of the three species the principal is the chamærops glabra, a native of the West Indies, Asia, and Africa. The leaves are broad and spread like a fan. They are used to cover huts with in some countries.

CHAMBERLAIN, an officer charged with the management and direction of a chamber.

There are almost as many kinds of chamberlains as chambers, the principal of which are as follow:

Chamberlain, *Lord, of great Britain*, the sixth great officer of the crown; to whom belongs livery and lodging in the king's court; and there are certain fees due to him from each archbishop or bishop when they perform their homage to the king: and from all peers at their creation, on doing their homage. This office is hereditary.

Chamberlain, *Lord of the Household*, an officer who has the oversight and direction of all the officers belonging to the King's chambers, except the precinct of the king's bed chamber.

Chamberlain of *London*, keeps the city money, which is laid up in the chamber of London: he also presides over the affairs of masters and apprentices, and makes free of the city, &c. His office lasts only one year; but the same person is usually re-chosen, unless charged with any misdemeanor in the management of the affairs of his office.

CHANCE, is more particularly used for the probability of an event; and is greater, or less, according to the number of chances by which it may happen, compared with the number of chances by which it may either happen or fail. Thus, if an event has three chances to happen, and two to fail, the probability of its happening may be estimated $\frac{3}{5}$, and the probability of its failing $\frac{2}{5}$. Therefore, if the probabilities are added together, the sum will be equal to unity.

If the probabilities are unequal, there are odds for, or against, the happening or failing, which odds are proportional to the number of chances for happening or failing.

The expectation of obtaining any thing is estimated by the value of that thing, multiplied by the probability of obtaining it. The risk of losing any thing is estimated by the value of that thing, multiplied by the probability of losing it. If, from the expectations which the gamesters have upon the whole sum deposited, the sums they deposit are subtracted, there will remain the gain, if the difference is positive; or the loss, if it is negative. Again, if from the respective expectations which either gamester has upon the sum deposited by his adversary, the risk of losing what he himself deposits is subtracted, there will likewise remain his gain or loss.

If there is a certain number of chances by which the possession of a sum can be secured, and a certain number by which it may be lost, that sum may be insured for that part of it, which shall be to the whole, as the number of chances there are to lose is to the number of all the chances.

If two events have no dependence on each other, so that p be the number of chances by which the first may happen, and q the number of chances by which it may fail: and likewise, that r be the number of chances by which the second may happen, and s the number of chances by which it may fail: multiply $p+q$ by $r+s$, and the product $pr+qr+ps+qs$ will contain all the chances by which the happening or failing of the events may be varied among one another.

Hence it follows, that if a fraction expresses the probability of an event, and another frac

tion the probability of another event, and these two events are independent, the probability that these two events will happen, will be the product of the two fractions.

CHANCELLOR, an officer supposed originally to have been a notary or scribe under the emperors; and named cancellarius, because he sat behind a lattice, called cancellus, to avoid being crowded by the people.

Lord high chancellor of Great Britain, or lord keeper of the great seal, is the highest honour of the long robe; he is the first person of the realm next after the king, and princes of the blood, in all civil affairs; and is the chief administrator of justice next the sovereign, being the judge of the court of chancery, which is styled a court of equity. The jurisdiction of this court is of vast extent. Almost all causes of weight and moment, first or last, have their determination here. This court will not retain a suit for any thing under 10*l.* value, except in cases of charity, nor for lands under 40*s.* per annum.

Chancellor *of the exchequer*, an officer who presides in that court, and takes care of the interest of the crown. He is always in commission with the lord treasurer, for the letting of crown lands, &c. and has power, with others, to compound for forfeitures of lands, upon penal statutes: he has also great authority in managing the royal revenues, and national finances.

Chancellor *of the order of the garter*, is an officer who seals the commissions and mandates of the chapter; keeps the register of their proceedings; and delivers acts thereof under the seal of their order.

Chancellor *of an university*, is he who seals the diplomas, or letters of degrees, provision, &c. given in the university.

The chancellor of Oxford is usually one of the prime nobility, chosen by the members of the university in convocation.

CHANCERY, the grand court of equity and conscience, instituted to moderate the rigour of the other courts that are bound to the strict letter of the law.

CHANNEL, in hydrography, the deepest part of a river, harbour, strait, &c. which is most convenient for the track of shipping; also an arm of the sea running between an island and the main or continent, as the British Channel.

CHAOS, in zoology, a genus of insects belonging to the order of zoophyta. The body has no covering, and is capable of reviving after appearing to be dead for a considerable time. It has no joints, or external organs of sensation. There are five species, mostly obtained by infusions of different vegetables in water, and only discoverable by the microscope.

CHARACTER, in a general sense, denotes any mark whatever, serving to represent either things or ideas; thus, letters are characters, types, or marks of certain sounds, words, or ideas, &c.

Character is also used in several of the arts, for a symbol, contrived for the more concise and immediate conveyance of the knowledge of things.

CHARADRIUS, in ornithology, a genus belonging to the order of grallæ. Among the species, of which there are 27 or 28, are,

1. The Alexandrius, or Alexandrian dottrel, is of a brownish colour, with the forehead, collar, and belly white; the prime tail feathers are white; and the legs are black. It is about the size of a lark, and lives upon insects.

2. The Ægyptius has a black streak on the breast, white eye-brows, the prime tail feathers streaked with black at the points, and blueish legs. It is principally found in the plains of Egypt.

3. The morinellus has an iron-coloured breast, a small white streak on the breast and eye-brows, and black legs. It is found in Cambridgeshire, Lincolnshire, and Derbyshire.

4. The pluvialis is black above, with green spots, white underneath, and the feet are ash-coloured, It is the green plover of Ray, and is a native of Europe

5. The œdicnemus, or stone curlew of Ray, is of a grey colour, with two of the prime wing-feathers black, but white in the middle it has a sharp bill, and ash-coloured feet; and is about the size of a crow. In Hampshire, Norfolk, and Lincoln, it is called the curlew, from a similarity of colours to the curlew These birds feed in the night on worms and caterpillars: they will also eat toads, and catch mice.

CHARCOAL is wood burnt through, and suddenly extinguished by being covered with fresh earth. It is perhaps one of the most durable substances with which we are acquainted, not being decomposed either by the air or the water.

The chief use to which charcoal is applied is fuel, but it is also employed as a tooth powder, to purify tainted meat and water. For the first process no mode of preparation is necessary, and for the others it is sufficient to reduce it to a powder. It forms an indispensable constituent in the manufacture of gunpowder.

CHARGE, in gunnery, the quantity of gunpowder and ball wherewith a gun is loaded. The rules for charging large pieces in war are, that the piece be first cleaned or scoured within side; that the proper quantity of powder be next driven in and rammed down: care being taken, that the powder in ramming be not bruised, because that weakens its effect; that a little quantity of paper, hay, lint, or the like, be rammed over it: and that the ball or shot be intruded. If the ball be red-hot, a tampion, or trencher of green wood is to be driven in before it. The weight of the powder necessary for a charge is commonly in a subduple proportion to that of the ball.

Charge, in heraldry, is applied to the figures represented on the escutcheon, by which the bearers are distinguished from one another.

CHART, or hydrographical map, is a representation of a part, or the whole of the water on the surface of the earth in plano. See the article Map.

CHARTA, *magna*, an ancient instrument, containing several privileges and liberties granted to the church and state by Edward the Confessor together with others relating to

the feudal laws of William the Conqueror, granted by Henry I. all confirmed by the succeeding princes.

CHECK, or *check roll*, a book containing the names of such persons as are attendants and in pay to the king, or other great personages.

Clerk of the **Check**, in the king's household, has the check and control of the yeomen of the guard, and all the ushers belonging to the royal family.

Checks, or *drafts*, on bankers, are bills made payable to the bearer by those who hold money in the banker's hands. They are equally negotiable with bills, although, strictly speaking, not due before payment is demanded. Checks ought to be presented for payment on the day they are received.

CHECKY, in heraldry, is when the shield, or a part thereof, as a bordure, &c. is divided into chequers or squares.

CHEEKS, among mechanics, are those pieces of machines that are double, and perfectly alike.

Cheeks, in ship-building, two pieces of timber, fitted on each side of the mast, at the top, serving to strengthen the mast there, and having holes in them, called hounds, through which the ties run to hoist the yards. Also the uppermost rail, or piece of timber in the beak of a ship.

CHEIRANTHUS, *stock gilliflower*, and *wallflower:* a genus of the 39th natural order, siliquosæ, and belonging to the tetradynamia class of plants. There are 22 species, of which the following are most worthy of notice.

1. Cheiranthus annuus, or ten weeks' stock, with an upright, woody, smooth stalk, divided into a branchy head, with spear-shaped leaves, and all the branches terminated by numerous flowers, of different colours in different varieties.

2. Cheiranthus cheiri, or the common wallflower, &c.

3. Cheiranthus incanus, the hoary cheiranthus grows from one to two or three feet high, of different colours in different varieties. The two last sorts are very hardy evergreen biennials or perennials; but the first must be continued by seed sown every year.

CHEKAO, a kind of paste, prepared by calcination and trituration from a hard stony substance. The Chinese use the chekao in drawing the elegant figures we see in the wholly white China ware, which they afterwards varnish in the common way.

CHELIDONIUM, *celandine*, *horned* or *prickly poppy:* a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 27th order, rhœadeæ. The corolla is tetrapetalous, the calyx diphyllous, the siliqua unilocular and linear. There are five species. One of them, viz. chelidonium majus, grows on old walls, among rubbish, and in waste shady places. It is of a bluish green colour; the root of a deep red; and both contain a gold-coloured juice. The juice takes off warts; and cures tetters, ring-worms, and the itch.

CHELONE, in botany, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There are five species, all natives of North America.

CHEMISTRY is the science which investigates the composition of material substances, and the permanent changes of constitution which their mutual actions produce.

In no science does modern improvement appear so conspicuous; and in none can it boast of so extensive utility as in chemistry. Such, indeed, is the present state of chemical science, that it might be pronounced perfect, were it not that the progress which it is making at the present hour, seems to point out the absurdity of attempting to circumscribe it within any limits whatever.

Writers on this subject vary from each other considerably with regard to the order in which they treat its different parts. In the earlier works on chemistry, the operative part usually precedes the theoretical. Some writers treat of compound bodies, and deduce their component parts in the way of analysis; while others begin with the habitudes or powers by which the several changes are effected. But it must be acknowledged that every one of the phenomena of chemistry is, notwithstanding the brilliant discoveries already made, still sufficiently complicated to render it referrable to various topics of consideration; so that, generally speaking, it is a matter of little moment to which of these our attention is first directed. Without, therefore, deciding as to the respective merits of these different methods of procedure we shall, in the following brief outline, adopt that which to us appears the most natural, commencing with the *simple substances.*

By simple substances, in a chemical sense, are to be understood those bodies which have not hitherto been decompounded. Many substances, denominated simple by the old chemists, have been, by the moderns, clearly ascertained to be compounds; such, for instance, is atmospheric air; and such also is water. Several substances also, which, but a few years ago, were considered as simple, have been decomposed by Sir H. Davy, and their component parts satisfactorily exhibited to the senses; of this description are the alkalis and earths.

SIMPLE SUBSTANCES.

These may be said to be, 1. *Simple supporters of combustion.* 2. *Simple combustibles.* 3. *Simple incombustibles.* 4. *Metals.*

SIMPLE SUPPORTERS OF COMBUSTION.

1. Oxygen. This substance is so named from two Greek words which signify the production of acid, as one of its properties is the formation of acids by combining with different substances, termed the bases of the acids. Oxygen is one of the most important agents in nature; there is hardly any process, natural or artificial, in which it has not a share. The principal sources whence it is obtained are air and water: in air it is combined with nearly one third of its weight of hydrogen: in water it is united with azotic, or nitrogen gas, and forms about ⅕ of the atmosphere, the other ⅘ths are nitrogen.

It is, however, obtained in the greatest abundance by submitting the black oxide of manganese to a red heat in an iron retort; almost all the metallic oxides will give out oxygen; but when it is wanted in a state of great

purity it should be obtained from oxymuriate of potash.

Oxygen gas possesses the mechanical properties of common air: it is termed a supporter of combustion, because although not inflammable itself, it is the most powerful supporter of combustion.

2. *Chlorine.* This substance was first discovered by Scheele, who called it *dephlogisticated muriatic acid.*

Like oxygen, it has an affinity for a great number of bodies, and uniting with them, forms compounds of a peculiar nature; it has been found by the experiments of Sir H. Davy to be destitute of oxygen, and yet is in some respects a more powerful supporter of combustion than oxygen itself. Chlorine is obtained by distilling a mixture of black oxide of manganese with muriatic acid. When this mixture is heated, a green coloured gas rises from it, which may be collected in the common way over water. Several substances, as phosphorus, antimony, &c. take fire of their own accord when plunged into this gas. The term chlorine was assigned to it by Sir H. Davy as descriptive of its colour.

SIMPLE COMBUSTIBLES

1. *Hydrogen,* which like oxygen, is a gas, and was first called inflammable air: its discovery belongs to Mr. Cavendish. It is the lightest of all gaseous bodies; is colourless, invisible, and possesses the mechanical properties of air. Hydrogen may be obtained by putting some clean iron-filings or small chippings into a glass retort, and pouring over them sulphuric acid diluted with thrice its bulk of water. A violent effervescence instantly takes place; gas issues in abundance from the beak of the retort, which may be received over water. This gas, although combustible when in contact with atmospheric air, extinguishes a taper, or even lighted phosphorus when immersed in it. Its specific gravity is 0.0694; and from its great levity it is used for inflating baloons

2. *Carbon,* in its purest form, is known only in the *diamond;* but it may be procured in a state of *charcoal* by burning a piece of wood covered with sand, in a crucible. Charcoal, the combination with which we are the most familiar, is the coaly residuum of any vegetable that has been burned in close vessels. It is generally black, sonorous, brittle, very light, and destitute of taste or smell. Charcoal is a powerful antiseptic, has great affinity for oxygen, is unalterable and indestructible by age, and, if air and moisture be excluded, is not affected by the most intense heat.

Phosphorus. This substance is obtained by pouring acetate of lead into urine, and distilling the white powder which precipitates, with some charcoal, in an earthen retort, by means of a strong heat. The beak of the retort must be inserted in water; the phosphorus will drop into the water like melted wax. Phosphorus, when pure, is semi-transparent; of a yellowish colour: it is soft, and may be cut with a knife. It melts at the temperature of 99°. When exposed to the air it emits a white smoke, which in the dark is luminous. It must be kept in phials of water, closely corked up. The compounds which phosphorus forms with other substances are denominated *phosphorets.*

4. *Sulphur.* This is one of those combustible substances which have the greatest tendency to combination. It is a hard brittle substance of a yellow colour, and with little taste. It is a non-conductor of electricity; and becomes electric *negatively* by friction. At the heat of 170° it rises up in the form of a fine white powder, well known by the name of flowers of sulphur.

5. *Boracium.* This substance was discovered by Sir H. Davy. To procure it, equal parts of the metal called potassium and dry boracic acid must, for a few minutes, be exposed in a copper-tube to a slight red heat. When cold, the mass must be washed out with water, and the potash saturated with muriatic acid, and the whole filtered. The matter which remains must be washed and dried, and this is *boracium.* It is of a dark olive colour, opaque, and brittle, and has some resemblance to charcoal.

SIMPLE INCOMBUSTIBLES.

The only substance under this head with which we are at present acquainted is *azote,* which is also called *nitrogen.* This gas is invisible; possesses the mechanical properties of air; it neither supports flame nor animal life, and although incombustible, it is capable of being combined with oxygen gas. It enters into combination with but few substances.

METALS.

Metals are distinguished by their peculiar lustre, called the metallic lustre: they are opaque, except gold, even in the thinnest plates to which they can be reduced. All the old metals are heavier than water; but some of the new metals discovered by Sir H. Davy are lighter than water. They are the best conductors of electricity known; they are all *soft,* although some of them have a capacity for great hardness, which may be artificially produced, as may also their elasticity. Some of them are *malleable,* while others are extremely *brittle;* some are *ductile,* and may be drawn into very fine wires, others are destitute of this property. Several of them take fire when heated, and burn with great splendour; and almost all of them may be burnt by peculiar contrivances.

The following are the principal metals now known.

Of Gold.

Gold is always found in nature in a metallic state. It is generally met with in grains, called gold-dust, mixed with the sand of rivers; being carried away by them from the rocks and mountains, where it is found in leaves or ramifications, adhering to quartz, and other stones.

It is of a rich yellow colour; and is the heaviest of metals, except plantina. It is not very hard when pure. It is the most ductile of all the metals. It cannot be oxidated by any heat of a furnace, but may by electricity and galvanism.

Gold is not acted upon by any acid, except the oxygenated muriatic, or nitro-muriatic acids, which latter was called from this aqua regia, because gold was named by the alchymists the king of the metals. With silver it forms an alloy of considerable ductility. Copper heightens its colour, and renders it harder

Tin and lead considerably impair its tenacity. With platina it forms an alloy which is very ductile. With zinc it affords a brittle and hard mixture, susceptible of polish. It unites well with iron, and hardens it remarkably.

On account of its peculiar property of not tarnishing in the air, it is much used for defending other metals; and on account of its beautiful lustre, it is much employed in ornaments. Its specific gravity is 19.3.

Of Platina.

Pure or refined platina is by much the heaviest body in nature. Its sp. gr. is 21.5. It is very malleable, though considerably harder than either gold or silver; and it hardens much under the hammer. Its colour on the touchstone is not distinguishable from that of silver. Pure platina requires a very strong heat to melt it; but when urged by a white heat, its parts will adhere together by hammering. This property, which is distinguished by the name of welding, is peculiar to platina and iron, which resemble each other likewise in their infusibility.

Platina is not altered by exposure to air; neither is it acted upon by the most concentrated simple acids, even when boiling, or distilled from it. Its ore has recently been found to contain, likewise, four new metals, palladium, iridium, osmium, and rhodium; which see; beside iron and chrome.

Of Silver.

Silver is the whitest of all metals, considerably harder than gold, very ductile and malleable, but less malleable than gold; for the continuity of its parts begins to break when it is hammered out into leaves of about the hundred and sixty thousandth of an inch thick, which is more than one-third thicker than gold leaf; in this state it does not transmit the light. Its specific gravity is from 10.4 to 10.5. It ignites before melting, and requires a strong heat to fuse it. The heat of common furnaces is insufficient to oxidize it; but the heat of the most powerful burning lenses vitrifies a portion of it, and causes it to emit fumes; which, when received on a plate of gold, are found to be silver in the metallic state. It has likewise been partly oxidized by twenty successive exposures to the heat of the porcelain furnace at Sevres. By passing a strong electric shock through a silver wire, it may be converted into a black oxide; and by a powerful galvanic battery, silver leaf may be made to burn with a beautiful green light. Lavoisier oxidized it by the blowpipe and oxygen gas; and a fine silver wire burns in the kindled united stream of oxygen and hydrogen gases. The air alters it very little, though it is disposed to obtain a thin purple or black coating from the sulphurous vapours, which are emitted from animal substances, drains, or putrefying matters. This coating, after a long series of years, has been observed to scale off from images of silver exposed in churches; and was found, on examination, to consist of silver united with sulphur.

Of Mercury.

Mercury, called also quicksilver, always appears in a liquid state, in the common temperature of the atmosphere; but in intense cold, as at 40 below zero, it becomes solid, and is then malleable, resembling silver. It is found in nature, sometimes in a pure state, but chiefly united to sulphur, when it forms cinnabar; and sometimes to silver. It is also united to the acids, and to oxygen. It is mostly found in Spain and South America. Like other fluids, it boils, and is converted into vapour. This process is employed to separate it from other substances. It is acted upon by most of the acids. It combines with sulphur and phosphorus; and forms alloys with most of the metals, which are then called amalgams. On this property depend some of the methods of gilding and of silvering mirrors. When acted upon by heat and air for a long time, it absorbs oxygen, and is converted into a real oxide, called precipitate per se, or red oxide of mercury. When the heat is increased, this oxide gives out its oxygen, the mercury reassuming its metallic appearance. When agitated long in air, mercury is converted into a black oxide.

Of Palladium.

This is a new metal, first found by Dr. Wollaston associated with platina, among the grains of which he supposes its ore to exist, or an alloy of it with iridium and osmium, scarcely distinguishable from the crude platina, though it is harder and heavier.

If crude platina be dissolved in nitro-muriatic acid, and precipitated with a solution of muriate of ammonia in hot water; the precipitate washed, and the water added to the remaining solution, and a piece of clean zinc be immersed in this liquid, till no farther action on it takes place; the precipitate now thrown down will be a black powder, commonly consisting of platina, palladium, iridium, rhodium, copper, and lead. The lead and copper may be separated by dilute nitric acid. The remainder being then digested in nitro-muriatic acid, and common salt about half the weight of the precipitate added on the solution, on evaporating this to dryness by a gentle heat, the result will be triple salts of muriate of soda with platina, palladium, and rhodium. Alcohol will dissolve the first and second of these; and the small portion of platina may be precipitated by sal ammoniac. The solution being diluted, and prussiate of potash added, a precipitate will be thrown down, at first of a deep orange, and afterward changing green. This being dried, and heated with a little sulphur before the blow-pipe, fuses into a globule, from which the sulphur may be expelled by exposing it to the extremity of the flame, and the palladium will remain spongy and malleable.

It may likewise be obtained by dissolving an ounce of nitrate of potash in five of muriatic acid, and in this mixture digesting the compound precipitate mentioned above. Or more simply by adding to a solution of crude platina, a solution of prussiate of mercury, on which a flocculent precipitate will gradually be formed, of a yellowish-white colour. This is prussiate of palladium, from which the acid may be expelled by heat.

Palladium is of a greyish-white colour, scarcely distinguishable from platina, and takes a good polish. It is ductile and very malleable; and being reduced into thin slips is flexible, but not very elastic. Its fracture is fibrous, and in diverging striæ, showing a kind of crystalline arrangement. In hardness it is superior to wrought iron. Its specific gravity is from 10.9 to 11.8.

Of Rhodium.

Rhodium exists in crude platina, and was discovered by Dr. Wollaston. It is of a white colour; no degree of heat that has yet been applied to it is capable of melting it, of course many of its properties remain unknown. When united with sulphur it is readily melted; and it forms an alloy with most of the metals except mercury.

Of Iridium.

This substance was discovered by Mr. Tennant in 1803. When crude platina is dissolved in nitro-muriatic acid, a black powder remains, which preceding chemists supposed to be plumbago, but which Mr. Tennant ascertained to be a compound of two new metals. This metal is in appearance like platina, and appears to be as difficult of fusion as that metal, and even more so. It resists the action of the acids; it forms alloys with all the metals tried except arsenic.

Of Osmium.

Osmium was also discovered by Mr. Tennant at the same time with the preceding. It exists in the black powder precipitated during the solution of crude platina. Its name is derived from its peculiar smell. It is of a dark grey or blue colour; resists the action of all the acids: is easily oxidized by heat in the open air; and may be amalgamated with mercury.

Of Copper.

Copper is a metal of a peculiar reddish colour; hard, sonorous, very malleable and ductile, and of great tenacity: specific gravity from 8.6 to 8.9. Besides its employment to make vessels of capacity, and to sheathe the bottom of ships, it is alloyed with zinc to make brass; it is combined with sulphuric acid to form Roman vitriol; and its oxides are employed in enamel painting, and in the manufacture of several colours.

Of Iron.

No metal is so widely diffused through nature as iron, most mineral bodies or stones being found with an admixture of it. Sands, clays, the waters of rivers and springs, are scarcely ever perfectly free from it. The parts of animal and vegetable substances also afford iron in the residues they leave after incineration. In its native state iron is very scarce; most iron being found in the state of oxide, in ochres, and bog-ores, and other earthy substances. The magnet or load-stone is an ore of iron.

Iron is of a bluish white colour, of considerable hardness, and elasticity; very malleable, and exceedingly tenacious. From the intense heat requisite to fuse it, it can only be brought into the shape required by hammering. In a white heat it appears as if covered with a kind of varnish; and in this state two pieces of it when applied together will adhere and may be perfectly united by forging, this process is termed welding, and can be applied to no other metal except platina. Iron is easily oxidized. An iron wire, ignited at one end by a brimstone match attached to it, and plunged into a glass jar of oxygen gas, will be entirely consumed by the successive combustion of its

Highly concentrated sulphuric acid has little effect on iron; but if the acid be diluted with about three parts of water, a violent action takes place, the iron is dissolved, and during the solution large quantities of hydrogen gas escape.

The substances known by the names of steel, and cast-iron, are combinations of iron with different degrees of carbon.

Iron is one of the principal ingredients in dyeing black, and in the manufacture of writing ink. Leather prepared by tanning with oak bark, is blackened by a solution of sulphate of iron.

Of Nickel.

Nickel is a metal of great hardness, of a uniform texture, and of a colour between silver and tin; very difficult to be purified, and magnetical. It even acquires polarity by the touch. It is malleable, both cold and red-hot; and is scarcely more fusible than manganese. Its oxides, when pure, are reducible by a sufficient heat without combustible matter; and it is little more tarnished by heating in contact with air, than platina, gold, and silver. Its specific gravity, when cast, is 8.279; when forged, 8.666.

Nickel is commonly obtained from its sulphuret, the kufernickel of the Germans, in which it is generally mixed also with arsenic, iron, and cobalt. The alloys which it forms are but imperfectly known: they are brittle and hard, and have never been applied to any useful purpose.

Of Tin.

Tin is of a fine white colour, with a shade of blue: it has a slightly disagreeable taste, and when rubbed emits a peculiar smell. Its specific gravity when hammered is 7.299. It quickly tarnishes when exposed to the air; but is not altered when kept under water. It is the brightest of metals, and very ductile, but at the same time tenacious and flexible. It enters into combination with most other metals, and its alloys are highly useful in the manufacture of hardware goods.

Of Lead.

Lead is of a bluish white colour, and when newly melted is very bright, but soon tarnishes when exposed to the air. It is the softest of all the metals; it does not become harder by hammering; it may be reduced to very thin plates, but its tenacity and ductility are not considerable. The use of lead is very extensive. Of the oxides of lead there are; 1. the powder precipitated by potash from the nitrate of lead; this is termed the yellow protoxide, which, when somewhat vitrified, constitutes litharge, and, when combined with carbonic acid, white lead, or ceruse. 2. When massicot has been exposed for about 48 hours to the flame of a reverberatory furnace it becomes red-lead, or minium. 3. If upon 100 parts of red-led we digest nitric acid of the specific gravity 1.26, part of it will be dissolved, the remaining part is peroxide of lead. The specific gravity of lead is 11.407.

Of Zinc.

Zinc is of a brilliant white colour, with a shade of blue, and is composed of thin plates cohering together. It is somewhat harder than silver. Its specific gravity when hammered is 7 1908. Zinc was formerly supposed not to be ductile: but if heated to a little above 212°, it becomes very malleable, and may be drawn into wires. Combined with copper, zinc forms one of the most useful alloys, namely brass.

The sulphuric acid diluted with water dis-

solves zinc very rapidly; in this process the water is decomposed, and much hydrogen escapes. By evaporating the liquor, sulphate of zinc, or white vitriol may be obtained in crystals.

Of Bismuth.

Bismuth is of a reddish white colour, and is usually found in silver and tin mines. It is composed of broad brilliant plates adhering to each other, and is harder than silver. Its specific gravity is 9.882. *Bismuth is not malleable; it is used chiefly in the composition of pewter, solder, printing types, &c.*

Of Antimony.

See ANTIMONY.

Of Tellurium.

This metal is of a bluish white colour, its texture laminated, and its brilliancy considerable. It is very brittle; its specific gravity 6.115. It melts a little above the melting point of lead. When exposed to the action of the blow-pipe, it burns with a bluish flame, and is converted into a white oxide. It may be combined with sulphur by fusion, and amalgamated with mercury. The metallic alloys which it is capable of forming are not known.

Of Arsenic.

Arsenic is often found native. When combined with sulphur it is called orpiment. It is also often united with metals. See ARSENIC.

Of Cobalt.

Cobalt is a brittle, somewhat soft, but difficultly fusible metal, of a reddish-grey colour, of little lustre, and a specific gravity of 8.6. Its melting point is said to be 130° Wedgewood. It is generally associated in its ores with nickel, arsenic, iron, and copper; and the cobalt of commerce usually contains a proportion of these metals.

Cobalt is susceptible of magnetism, but in a lower degree than steel and nickel.

Of Manganese.

Manganese is a metal of a dull whitish colour when broken, but which soon grows dark by oxidation, from the action of the air. It is hard, brittle, though not pulverizable, and rough in its fracture; so difficultly fusible, that no heat yet exhibited has caused it to run into masses of any considerable magnitude. Its specific gravity is 8.0. When broken in pieces, it falls into a powder by spontaneous oxidation.

The black oxide of manganese is found very generally. It is procured in the greatest purity in the neighbourhood of Exeter, and is very much used for obtaining the oxygenated muriatic acid gas employed in bleaching. It is also used by glass-makers for destroying the green or yellow tint of glass; and for this reason has been called glass-maker's soap. It is also employed for giving a violet colour to glass and porcelain. In a metallic state it is of a grey colour, not at all malleable, and more infusible than iron.

Where oxygen gas is wanted for philosophical experiments, the black oxide of manganese will be found to furnish it, at a cheap rate, in greater abundance than any other substance known to yield it.

Of Chromium.

This metal was first discovered by Vauquelin, who extracted it from the red lead ore of Siberia. Its colour is white, specific gravity 5.90. It is brittle; takes a good polish, and is magnetic, but less so than nickel and cobalt. Both heat and the acids act upon it with difficulty; on this account it has hitherto been met with only in small grains.

Of Uranium.

This metal is but little known; and it appears doubtful if it has ever been obtained in a state of purity, since the different specimens of different chemists have all differed in specific gravity. It has been found in France; *and some specimens of great beauty have been found in Cornwall. It is of a grey colour;* brittle, and extremely difficult of fusion.

Of Molybdenum.

Molybdenum is a metal which has not yet been reduced into masses of any magnitude; but has been obtained only in small separate globules, in a blackish brilliant mass. This may be effected by making its acid into a paste with oil, bedding it in charcoal in a crucible, and exposing it to an intense heat.

Of Tungsten.

Tungsten is obtained by exposing a mixture of tungstic acid and charcoal to a strong heat. The name given to this metal signifies heavy stone. It is of an iron colour, very hard, and brittle, and difficult of fusion. According to Professor Brande, its specific gravity is 17.5. By the action of heat and air it is converted into an oxide, which is of a yellow colour.

Of Columbium.

This metal, as its name imports, was discovered in a mineral from North America, by Mr. Hatchett. Berzelius appears to be the only person who has succeeded in obtaining Columbium. He describes it as having the colour of iron; as being very hard, and brittle; and burning at a red heat into a whitish oxide.

Of Titanium.

This name was given to a metallic substance discovered by Mr. Gregor in a kind of ferruginous sand found in Cornwall. It is so refractory that most persons have failed in their attempts to reduce it. Lampadius is said to have succeeded. Its colour is that of copper; with a metallic brilliancy; is very brittle, but in small scales it is very elastic.

Of Cerium.

Cerium was obtained by Hisinger and Berzelius from a mineral found in Sweden, to which they gave the name of *Cerite.* This metal is extremely difficult of fusion: Mr. Children, however, succeeded in fusing it by the aid of his powerful voltaic apparatus. It burned with a vivid flame, and was partly volatilized. It is a hard, white, brittle metal.

Of Potassium.

This metal was discovered by Sir H. Davy in 1807. He obtained it by submitting caustic potash to the action of voltaic electricity; the metal was slowly evolved at the negative pole. Potassium is a white metal of great lustre; it is ductile, and of the consistency of soft wax. It is lighter than water, its specific gravity being 0.85. When exposed to the air it instantly tarnishes, and must be kept in pure naphtha. It is a conductor of electricity. When thrown upon water, it acts with great violence, and swims on the surface, burning with a beautiful light of a red colour. The water becomes a solution of pure potash

On all fluid bodies which contain water, or much oxygen or chlorine, it readily acts; and

in its general powers of chemical combination, says its illustrious discoverer, potassium may be compared to the alkahest, or universal solvent, imagined by the alchemists.

Of Sodium.

This metallic substance appears to be the basis of soda, and was discovered by Sir H. Davy a few days after he discovered potassium. It is procured in the same way as potassium, which it resembles in many of its properties. It operates on most substances in a similar manner, but with less energy; and to keep it from tarnishing it must be preserved in naphtha.

Of Barium.

According to Sir H. Davy, barium is of a grey colour, about twice the weight of water. It greedily absorbs oxygen, and burns with a deep red light when gently heated, producing the oxide of barium. It is the metallic basis of the earth called barytes; and is produced by the application of the voltaic apparatus. See Barium.

OF LIGHT.

The physical properties of light will be considered under Optics. This substance seems to have considerable influence upon many chemical processes. The effect of light upon vegetation is well known. Many flowers follow the course of the sun; and plants that grow in houses, seem solicitous to turn to the light. Plants that grow in the shade, or in darkness, are pale, and without colour: and when this is the case, they are said to be etiolated or blanched. Gardeners avail themselves of this fact to render vegetables white and tender. The more plants are exposed to the light, the more colour they acquire. Yet the dead vegetable is deprived of colour by exposure to it.

Vegetables are not only indebted to light for their colour, their taste and odour are derived from the same source. From this cause it happens that hot climates are the native countries of perfumes, odoriferous fruits, and aromatic resins. The action of light on the organs of vegetables causes them to pour out streams of pure air from the surfaces of their leaves, while exposed to the sun: whereas, on the contrary, when in the shade, they emit air of a noxious quality. Even animals, in general, droop when deprived of light; and it appears to be of great importance to the health and happiness of human beings.

OF CALORIC.

The general opinion on the nature of caloric seems now to be that it is a peculiar substance, and not, as was formerly supposed, a mere property of matter. This opinion has been much strengthened by the discovery of Dr. Herschell, who found, while examining the sun by means of telescopes, that the most refrangible rays have the least heating power; and that the heating power gradually increases as the refrangibility diminishes. From these experiments it was concluded that the rays of caloric, proceeding from the sun, are not the same with the rays of light. See Caloric.

OF EARTHS.

Those substances known by the name of earths are nine in number and are by chemists divided into *Alkaline* earths, and earths proper. The leading properties of earths are the following.

1. Insolubility in water, or at least becoming so when combined with carbonic acid.
2. Little or no taste or smell, at least when combined with carbonic acid.
3. Fixed, incombustible, and incapable, when pure, of being altered by fire.
4. A specific gravity not exceeding 4.9.
5. When pure, capable of assuming the form of a white powder.
6. Not altered when heated with combustibles.

Of the Alkaline Earths.

1. *Lime.*—Lime is seldom found in a pure state; it is contained in chalk, which may be deemed a neutral salt, being formed by the combination of lime with carbonic acid. The best process for obtaining lime in a state of purity is this: wash chalk in distilled water, brought to a state of ebullition, and then dissolve it in distilled acetous acid: this acid, by combining with the lime, expels the carbonic acid, which escapes under the gaseous form; then precipitate the lime by carbonate of ammonia, for the acetous acid abandons the lime, in order to combine with the ammonia, and the lime is precipitated: wash and calcine this precipitate, and the residuum will be pure lime.

Lime is soluble in water, but in very small quantities; more than 600 parts of water are necessary to dissolve one of it. It has a pungent, hot, and acrid taste; it turns blue vegetable colours green. It takes up water with avidity. When thrown into this liquid it splits, swells up, acquires a larger volume, and a great heat. It dissolves in acids without effervescence. The borate of soda and the phosphates of urine dissolve it also.

Lime, when alone, is infusible, even though the fire may be urged by oxygen gas, as has been proved by Lavoisier; but if combined with acids, it forms a fusible body, for lime is a salifiable base. Of all these bases it is that most abundantly diffused throughout nature.

2. *Magnesia.*—Magnesia has never yet been found free from every kind of foreign matter. To procure it in the utmost degree of purity, crystals of the sulphate of magnesia (Epsom salt,) of which it forms the base, must be dissolved in distilled water, and decomposed by alkaline carbonates: the sulphuric acid combines with the alkalis; the magnesia with the carbonic acid, and is precipitated. This precipitate must then be calcined, in order to disengage the carbonic acid; and what remains will be pure magnesia.

Pure magnesia is exceedingly white, tender, and in appearance spongy. When perfectly pure, it is not sensibly soluble in water. It excites no sensible savour on the tongue; and in this respect it is greatly different from lime.

3. *Barytes.*—Barytes, or ponderous earth, has never yet been found pure and free from all combination It is found under the pulverulent form, and exceedingly white. It gives a very slight tint of green to blue vegetable colours. Its specific gravity is from 4.2 to 4.3. Analysis has proved that 100 parts of carbonate of barytes contain 62 of barytes, 22 parts of carbonic acid, and 16 parts of water.

4. *Strontian.*—This earth was discovered by Dr. Hope, professor of Chemistry at Edinburgh. It is found in the state of a carbonate, that is, combined with carbonic acid, in a vein of lead ore, at Strontian in Argyleshire, in the western part of Scotland. It has been found also combined with carbonic acid at Lead-hills, in the same country. Some of it has since been discovered at Montmartre in France, combined with sulphuric acid; and it is found in quantities in the neighbourhood of Bristol.

Strontian was at first confounded with barytes which indeed it resembles in several respects, though it differs from it in others.

Carbonate of strontian is decomposed by the sulphuric acid, and carbonic acid is disengaged: the sulphate of strontian, thus obtained, is very little soluble in water. It dissolves with effervescence in the nitric and muriatic acids, and carbonic acid is disengaged. These nitrates and muriates of strontian are not deliquescent, and are decomposed by the sulphates of lime, potash, and others. It may be deprived of its acid by calcination; its earth is then soluble in water, but in greater quantity in boiling than in cold water, for a part of it is precipitated by cooling.

The carbonate of strontian is lighter than carbonate of barytes; the specific gravity of the latter is from 4.2, to 4.3, that of the carbonate of strontian is only from 3.6, to 3.7. Analysis has proved, that 100 parts of the carbonate of strontian contain 62 parts of strontian, 30 parts of carbonic acid, and 8 parts of water.

Of the Earths Proper.

1. *Alumina.*—Alumina, or pure argil, is found chiefly in the different kinds of clay, of which it forms the base, and where it is often mixed with silex. To obtain it very pure, sulphate of alumina (alum) must be dissolved in water, and afterwards decomposed by alkaline carbonates. The alkali combines with the sulphuric acid, which then abandons the alumina; and the latter combines with the carbonic acid abandoned by the alkali. The alumina must then be freed from this acid by calcination; and after this process it will remain pure. It absorbs water with avidity, and becomes diluted in that liquid. It adheres strongly to the tongue. The borate of soda and the phosphates of urine dissolve it. When exposed to heat, it becomes dry, shrinks, and cracks. By the action of the fire it acquires so great hardness as to strike fire with steel: it is then no longer susceptible of being diluted in water. Alumina, even when perfectly pure, is completely fusible in the fire, if urged by a current of oxygen gas. The result of its fusion is a vitreous, opaque, and very hard substance, which scratches glass in the same manner as precious stones do.

2. *Yttria.*—This earth was discovered by Gadoline in a Swedish mineral, of a black colour, to which the name of Gadolonite has been given. When prepared, it is a fine white powder without taste or smell; it is insoluble in water, and heat does not melt it. It is also insoluble in pure alkalis, but readily soluble in alkalis when carbonated. Sp. gr. 4.842.

3. *Glucina.*—Glucina is a simple earth, lately discovered by Vauquelin, in the aigue-marine, called the occidental. It is a white granular earth, which effervesces with acids. In 100 parts of the aigue-marine there are 14 of glucina. It is soluble in the carbonate of ammonia, as well as in the sulphuric acid. In the latter case, the solution has at first a saccharine, and afterwards an astringent taste. Its crystals are sweet, like the solution. It has some resemblance to alumina; as it is soft to the touch, adheres to the tongue, is light, dissolves in potash, and is precipitated from its solution by ammonia. But it differs from alumina by its combinations with acids, being exceedingly sweet, by giving no alum when mixed with sulphate of potash, by being entirely soluble in carbonate of ammonia, and by not being precipitated from its solutions by oxalate of potash and tartrite of potash, as alumina is.

It has been found by analysis, that 100 parts of earth contain 68 of silex, 15 of alumina, 14 of glucina, 2 of lime, and of the oxide of iron.

4. *Zirconia.*—Zirconia is a simple earth, lately discovered by Klaproth, in the jargon of Ceylon, of which it is a constituent part, and even the most abundant; for it has been found by analysis, that 100 parts of the jargon of Ceylon contain 64 parts and a half of zirconia, 32 parts of silex, and two parts and a half of the oxide of iron. To obtain zirconia pure, it must be united to the muriatic acid, with which it forms a muriate of zirconia: this muriate must be dissolved on a large quantity of water, and the zirconia must be precipitated by potash: if it is carefully washed, and then brought to a red heat in a crucible, it will be perfectly pure. Calcined zirconia has a white colour. It is rough to the touch like silex; it has no taste, and is not soluble in water. Its specific gravity is at least 4.3; that of distilled water being 1.0.

When separated from its solutions by caustic alkalis, this earth retains a pretty large quantity of water, which gives it the semi-transparency of horn; it has then the appearance of gum-arabic, both by its slightly yellow colour and its fracture and transparency. It is susceptible of uniting with carbonic acid. It unites also with the sulphuric and nitrous acids: alkalis, and the first six primitive earths, separate it from the latter acid. It will not alone fuse by the blowpipe; but it fuses with the borate of soda, and gives a transparent colourless glass.

5. *Silex, or Silica.*—Silex, or vitrifiable earth, is almost in its state of purity in rock-crystal: but to have it perfectly pure, one part of beautiful rock-crystal must be fused with four parts of pure alkali; the mixture must then be dissolved in water, and precipitated by an excess of acid: the precipitate will be pure silex, which is rough and harsh to the touch; its particles, when diluted in water, are easily precipitated.

The fluoric acid dissolves silex exceedingly well: it is also the solvent of glass. Alkalis dissolve silex in the dry way, and with it form glass. Silex cannot be fused by a burning lens; but by exposing it to a fire, urged by oxygen gas, Lavoisier produced a commencement of fusion on its surface.

OF COMPOUND SUBSTANCES.

1. *Water.*—It is scarcely necessary to give any definition or description of this universally

known fluid. It is a [illegible] fluid, possessing a moderate degree of activity with regard to organized substances, which renders it friendly to animal and vegetable life, for both which it is indeed indispensably necessary. Hence [illegible] acts but slightly on the organs of sense, and is therefore said to have neither taste nor smell. It appears to possess considerable elasticity, and yields in a perceptible degree to the pressure of air in the condensing machine, as Canton proved, by including it in an open glass vessel with a narrow neck.

The solubility or insolubility of bodies in this fluid composes a large part of the science of chemistry. See Salt.

Native water is seldom, if ever, found perfectly pure. The waters that flow within or upon the surface of the earth, contain various earthy, saline, metallic, vegetable, or animal particles, according to the substances over or through which they pass. Rain and snow waters are much purer than these, although they also contain whatever floats in the air, or has been exhaled along with the watery vapours.

The composition of water is best demonstrated by exploding 2 volumes of hydrogen and 1 of oxygen, in the eudiometer. They disappear totally, and pure water results.

II. *Alcohol.*—See Alcohol.

III. *Oils.*—The distinctive characters of oil are inflammability, insolubility in water, and fluidity, at least in a moderate temperature. Oils are distinguished into fixed or fat oils, which do not rise in distillation at the temperature of boiling water; and volatile or essential oils, which do rise at that temperature with water, or under 320° by themselves.

The volatile oil obtained by attenuating animal oil, by a number of successive distillations, is called Dippel's animal oil.

Monnet asserts, that, by mixing acids with animal oil, their rectification may be very much facilitated.

The addition of a little ether, before re-distillation of old essential oils, improves the flavour of the product.

IV. *Alkalis.*—The term alkali is now applied to all substances having the following properties.

1. A caustic taste. 2. Volatilized by heat. 3. Capable of combining with acids, and of destroying their acidity. 4. Soluble in water, even when combined with carbonic acid. 5. Capable of converting vegetable blues to green.

The alkalis at present known are these.

1. Ammonia; 2. Potash; 3. Soda. The first is called *volatile alkali*; the two last are called *fixed alkalis*. The alkalis will be found more fully described under their respective names.

V. *Acids.*—The name of *acid* is given to all substances, whether liquids or solids, which produce that sensation on the tongue, which we call *sour*; which change the blue juices of vegetables to *red*, and combine with alkalis, earths, or metallic oxides, so as to form those compounds called *salts*. When two acids have the same radical, but contain different quantities of oxygen, each acid is distinguished by its termination. The name of that which contains most oxygen ends in *ic*, the other in *ous*. Thus we say *sulphuric* acid, and *sulphurous* acid; *phosphoric* acid, and *phosphorous* acid. To express the presence of a greater quantity of oxygen, the word *oxygenized* is added to the name of the acid, as oxymuriatic acid (now chlorine).

2. The acids have been divided by Dr. Thomson into acid products, acid supporters, combustible acids, and colorific acids. i. Acid Products consist of *sulphuric* acid, formerly called oil of vitriol, and vitriolic acid; *sulphurous* acid; *phosphoric, phosphorous* acids; *carbonic* acid, formerly called fixed air; *boracic* acid, from the salt called borax; and *fluoric* acid, from the *fluor* spar, or Derbyshire spar. ii. Acid Supporters contain *nitric* acid, called aqua fortis and spirit of nitre; *nitrous* acid; *oxymuriatic* acid, or chlorine; and the *arsenic, tungstic, molybdic, chromic,* and *columbic* acids, obtained from the metals arsenic, tungsten, molybdenum, chronium, and columbium. iii. Combustible Acids, are *acetic* acid, from wine or beer; *benzoic*, from the resin called benzoin; *sebacic*, from fat; *succinic*, from amber; *moroxylic*, from a saline exudation on the bark of the white mulberry tree; *camphoric*, from camphor: *oxalic*, from the wood-sorrel; *mellitic*, from the mellite of honey-stone; *tartaric*, from tartar; *citric*, from oranges and lemons: *kinic*, from a salt in the jesuit's bark: *saclactic*, from sugar of milk; *uric*, in human calculi; *malic*, from apples; *suberic*, from cork; and the *formic*, from the red ant. iv. Colorific Acids, or those which cause colour, are the *prussic*, which is the colouring matter of prussian blue, and the *gallic* acid obtained from nut-galls, a concretion formed on the oak in consequence of the puncture of insects. The acids are indispensable in various arts and manufactures; are employed for culinary purposes, and in medicine: and act an important part in the great laboratory of nature.

The preceding may be denominated compounds of the *first order*: and hence those substances which consist of combinations of these are termed compounds of the *second order*, or *doubly compound* substances. These may be reduced to three classes. 1. Soaps. 2. Neutral salts. 3. Hydrosulphurets.

1. *Soaps.* The fixed oils have the property of combining with alkalis, earths, and metallic oxides, and the compounds thus formed have received the name of Soaps. These soaps differ from each other very materially, according as their base is an alkali, an earth, or a metallic oxide.

2. *Neutral salts.* The term *salt* was originally confined to common salt; it was afterwards generalized by chemists, and applied to all bodies which are sapid, easily melted, soluble in water, and not combustible. It was then confined to acids, alkalis, and the compounds formed by the union of these bodies with each other; but it is now applied to all the compounds which the acids form with alkalis, earths, and metallic oxides. Every species of salt is distinguished by subjoining to the generic term the name of its base. Thus the salt composed of sulphuric acid and soda, is called *sulphate of soda*. Triple salts are distinguished by subjoining the names of both the bases. Thus the salt composed of tartaric

acid, potash, and soda, is called tartrate of potash and soda.

3. *Hydrosulphurets.* Sulphuretted hydrogen gas possesses many of the properties of an acid, and, like acids, it combines with the salifiable bases, and forms a class of bodies called *hydrosulphurets.* These are of considerable importance, being frequently employed in chemical analysis, to separate the metallic oxides from alkalis and earths. They precipitate almost all the metals from their solutions.

OF CHEMICAL AFFINITY.

Chemical affinity is the attraction which exists between the particles of bodies, which urges them towards each other, and keeps them united. The characteristic marks of affinity may be reduced to the three following.

1. It acts only at insensible distances, and affects only the particles of bodies. 2. Its force is always the same in the same particles, but it is different in different particles. 3. This difference is not affected by the mass.

See Attraction.

CHEMICAL OPERATIONS AND INSTRUMENTS.

The reduction of solids into powders of different degrees of fineness, by *pulverization,* &c. is necessary previously to their being chemically acted upon. But these processes can never reduce substances into their primary or elementary particles: they do not even destroy the aggregation of bodies. The real chemical operations, on the contrary, separate their constituent particles from each other. Brittle substances are reduced to powder by means of hammers, pestles, and mortars, stones, and mullers. Wedgewood's ware affords a most excellent kind of mortar for most purposes, as it is very strong, and not liable to be acted upon by acids. Many bodies cannot be reduced to powder by the foregoing methods: such are fibrous substances, as wood, horns of animals, elastic gum, and metals which flatten under the hammer; for these, files, rasps, knives, and graters, are necessary.

The separation of the finer parts of bodies from the coarser, is performed by means of sifting or washing.

Washing is used for procuring powders of an uniform fineness. The powdered substance is mixed with water, or some other convenient fluid: the liquor is allowed to settle, and is then decanted off; the coarsest powder remains at the bottom of the vessel, and the finer passes over with the liquor. By repeated decantations in this manner, various sediments are obtained, of different degrees of fineness: the last, being the finest.

Filtration is a finer species of sifting. It is sifting through the pores of paper, or flannel, or fine linen, or sand, or pounded glass, or porous stones, and the like; but is used only for separating fluids from solids, or gross particles that may happen to be suspended in them, and not chemically combined with the fluids. Unsized paper is a very convenient substance for making filters for chemical purposes. It is wrapped up in a conical form, and put into a glass funnel, which serves to strengthen the paper and support the weight of the fluid when poured into it.

D[illegible] substituted instead of filtration, for [illegible]rating solid particles which are diffused thro[illegible] liquors. If the sediment is extremely light, and apt to mix again with the fluid, a syphon is used for drawing off the clear fluid.

Lixiviation is the separation by means of water, or other fluid, of such substances as are soluble in it, from those which are not. Thus, if a mineral consists of salt and sand, or salt and clay, &c. the given body being broken to powder, is placed in water, which will dissolve the salt, and keep it suspended, whilst the earthy matter falls to the bottom of the vessel, and, by means of filtration, may be separated from the fluid.

Evaporation separates a fluid from a solid, or a more volatile fluid from another which is less volatile.

Simple evaporation is used when the more volatile or fluid substance is not to be preserved. Various degrees of heat are employed for this purpose, according to the nature of the substances. It is performed in vessels of wood, glass, metal, porcelain, &c. Basons made of Wedgewood's ware are very convenient, as they are not apt to break by sudden changes of heat.

When the fluid which is evaporated must be preserved, then the operation is called *distillation,* which see.

Crystallization.—When a salt is dissolved in water, or other fluid, and by evaporation the fluid is driven off, the salt gradually acquires the solid form, and in doing this, it arranges its particles in different figures. Vessels of earthenware, or glass, are employed for such crystallizations.

Solution.—When a salt is mixed with water, it loses its state of solidity: the particles of salt are divided and unite themselves to those of the water. The same takes place when resin is mixed with spirits of wine. In this process neither the salt nor the water is decomposed; and the salt may be recovered again in its original state and quantity, by evaporation.

The dissolution of metals by acids, however, is of a different nature; here, either the metal, the acid, or the water, is altered, and different products are obtained. Vessels of glass are generally used for solutions and dissolutions. The liquid used for dissolving a metal, or other solid substance, is usually called a solvent, or menstruum.

Precipitation.—The recovery or separation of a body from its solvent, by the addition of a third substance, so that the former may reappear in a solid state, however divided, is called precipitation. The substance thus recovered, is called a precipitate, and the superadded body that occasions this precipitation is called a precipitant.

Fusion.—The melting of any body from the solid to the liquid state, by the action of fire, is called fusion. The fusion of metallic substances requires vessels sufficiently strong to resist the fire. These are mostly, if not always, made of earthen-ware, or porcelain, or a mixture of clay and powder of black-lead, and are called crucibles. Sometimes they have covers, but others are broad and shallow, that the fused metal may be exposed to a current of air. These are named cupels: and are placed

under a sort of oven, made of earthenware, called a muffle; which with the included cupel is exposed to the heat of the furnace.

Furnaces.—In the application of the action of hea[illegible] bodies, furnaces of different forms are employed, according to the operations for which they are intended. A furnace is a kind of hollow cylindric tower; sometimes a little wider at the top, with notches, to give a passage to the air. This furnace ought to have at least two lateral apertures; an upper one which is the door of the fire-hole, and a lower one which is the door of the ash-hole. In the interval between these doors the furnace is divided into two parts by a horizontal grate for supporting the charcoal.

Another kind of furnace often necessary, is that called the reverberating furnace; it consists of an ash-hole, a fire-hole, a laboratory, and a dome. In the laboratory is placed a retort, which is supported by two iron bars that run across the furnace; the neck of it passes through a lateral aperture, and has adapted to it a receiver. As a strong heat is sometimes required for this furnace, a large volume of air must be made to pass through it; and in that case a great deal of heat is disengaged. The use of the dome is to reverberate the heat and flame on the retort, in order that it may every where be exposed to nearly an equal heat.

For farther information on the subject of chemistry, particularly as it respects the latest discoveries, the reader is referred to the article ELECTRO-CHEMISTRY; and for a description of some of the principal articles of chemical apparatus, to the word LABORATORY.

CHENOLEA, a genus of the order monogynia, in the pentandria class of plants. The calyx is globular, one-leafed, five-parted, caps. one-celled, with one smooth seed. There is one species, a native of the Cape.

CHENOPODIUM, GOOSE-FOOT, or WILD ORACH, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is pentaphyllous and pentagonal; no corolla; one seed, lenticular, superior. There are 23 species, 13 of which are natives of Britain. Most of them have an aromatic smell. A species which grows near the Mediterranean is used by the Egyptians in sallads, on account of its saltish aromatic taste. From this plant kelp is made in other countries.

CHERLERIA, a genus of the decandria trigynia class of plants. The flower has properly no petals; the nectaria are five in number, roundish and emarginated, very small, and placed in a circular direction. The fruit is a capsule, formed of three valves, and containing three seeds. There is one species.

CHERMES, in zoology, a genus of insects belonging to the order hemiptera. There are 17 species. It is an insect to be met with in great numbers upon the fig-tree. The larva has six feet. The chrysalis differs from it by two flat buds that spring from the thorax, and inclose the wings. These chrysalids are frequently met with on plants.

CHERRY-*tree*, in botany, See PRUNUS.

CHESNUT-*tree*. See FAGUS.

CHESS, an ingenious game, performed with different pieces of wood, on a board divided into 64 squares or houses, in which chance has so small a share, that it may be doubted whether a person ever lost but by his own fault. Each gamester has eight dignified pieces, viz. a king, a queen, two bishops, two knights, and two rooks, also eight pawns; all which, for distinction' sake, are painted of two different colours, as white and black.

CHIEF, in heraldry, is that which takes up all the upper part of the escutcheon, from side to side, and represents a man's head.

CHILIAD, denotes a thousand of any things, ranged in several divisions, each of which contains that number.

CHILIAGON, in geometry, a regular plane figure of 1000 sides and angles.

CHIMARRHIS, a genus of the class and order pentandria monogynia. The essential character is; corolla funnel-formed; capsule inferior, obtuse; two-celled; two-valved; seeds one in each cell. There is one species, a lofty tree, a native of Martinico.

CHIMES *of a clock*, a kind of periodical music, produced at equal intervals of time, by means of a particular apparatus added to a clock.

CHIMNEY, in architecture, a particular part of a house, where the fire is made, having a tube or funnel to carry off the smoke. The effect of chimneys is often destroyed by their being constructed on unscientific principles. It will be found for the most part that the smoking of chimneys arises from their being carried up narrower at the top than at the bottom, and from their being thrown in a zig-zag direction. Now it is evident from the very principle on which smoke rises at all in a chimney, that the higher it rises the less is the force that drives it, and the slower it must move, and consequently the more room it should have to move in, whereas in the usual way it has less. Chimneys, therefore, should be built as nearly perpendicular as possible; they ought to be free from all roughness on the inside; and a few inches wider at the top than at the base. This would effectually prevent smoking; and might be so managed as not to interfere with the form of the exterior.

CHIOCOCCA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The corolla is funnel-shaped and equal; the berry unilocular, dispermous, inferior. There are two species.

CHIONANTHUS, the snow-drop, or fringe-tree, a genus of the monogynia order, belonging to the diandria class of plants, and in the natural method ranking under the 44th order, sepiariæ. The corolla is quadrifid, with the segments very long; the fruit is a plum. There are four species described by botanists. The most remarkable is the chionanthus Virginica, common in Virginia and South Carolina, where it grows by the side of rivulets. It rises to the height of ten feet.

CHIRONIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. There are 10 species, of which the most remarkable is the Chironia frutescens, a native of the Cape of Good Hope.

CHIVALRY, in antiquity, an institution which, according to some writers, took its rise from the crusades; but, according to others, it

gave occasion to that enterprise; and which, though founded in caprice, and productive of extravagance, had a very considerable influence in refining the manners of the European nations during the twelfth, thirteenth, fourteenth, and fifteenth centuries.

CHLORA, a genus of the monogynia order, and octandria class of plants. Calyx octophyllous; corolla, monopetalous and octofid; capsule, unilocular, bivalved, and polyspermous. There are four species.

CHLORANTHUS, in botany, a genus of the class and order tetrandria monogynia. Calyx none; corolla, three lobed; petal by the side of the germ; anthers growing to the petal; drupe seeded. There is one species, a native of China.

CHLORITES, a kind of green jasper almost as pellucid as the coarser emeralds. It is sometimes amorphous, and sometimes chrystalized. There are four species, viz. the earthy chlorite, common chlorite, the foliated and shistose chlorite.

CHOCOLATE, in commerce, a kind of paste, or cake, prepared chiefly from the cacao-nut.

When the cacao is properly roasted, and well cleaned, it is pounded in a mortar, and afterwards ground on a stone, the paste being sufficiently ground, it is put hot into tin moulds, in which it congeals in a very little time. Complaints are made, that the Spaniards mix with the cacao-nuts too great a quantity of cloves and cinnamon, besides other drugs, as musk, ambergris, &c. In England, the chocolate is made of the simple cacao, excepting that sometimes sugar, and sometimes vanilla, is added.

CHOLERA *morbus*. See Medicine.

CHONDRILLA, a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There are three species.

CHORD, in geometry, a ri[illegible] line drawn from one part of an arch of a circle to the other.

CHORDS, *line of*, one of the lines of the sector and plane scale.

Chords, in music, are strings, by the vibration of which the sensation of sound is excited, and by the divisions of which the several degrees of tune are determined.

CHOROGRAPHY, the art of delineating or describing some particular country or province: it differs from geography as a description of a particular country differs from that of the whole earth; and from topography, as a description of a country differs from that of a town or district.

CHROMATICS. See Optics.

CHRONOLOGY, from Χρονος, *time*, and Λογος, *doctrine*, is that science which treats of the natural and artificial divisions of time, and refers to the points which it thus marks out, the various events recorded in history. Chronology may be divided into, 1. Mathematical chronology, which treats of the division of time into days, months, years, and cycles, and of the application of these divisions to the purposes of civil life.

2. Historical chronology, which treats of the eras and epochs fixed upon by different nations for determining the order of dates and facts in their annals; or it may be said to treat of all those historical documents which are used for establishing the existence of events, and the order in which they happened; such as eclipses, public registers, medals, columns, obelisks pyramids, &c.

3. Comparative chronology, which treats of the comparison of different eras, and is of the greatest importance in facilitating the study of history.

4. Tabular chronology, or that branch of the science in which all the leading events recorded in history are arranged in the order of time in which they happened. Tables of this description should include all the great political events which accompany the rise and fall of empires: the most striking natural phenomena; and an account of all the great men who have acted a conspicuous part, as philosophers, statesmen, and warriors. Chronological tables, with problems, &c., and suitable rules for their solution are to be found in almost every elementary work on astronomy, on which account it is deemed unnecessary to introduce them here.

CHRONOMETER, an instrument or machine for measuring time. The word is more particularly used to denote a portable machine, in which, by the nature of the escapement and the compensations for heat and cold, mean time is, or ought to be, kept with sufficient accuracy to determine the longitude at sea.

CHRYSALIS, in natural history, a state of rest and seeming insensibility which butterflies, moths, and several other kinds of insects, must pass through before they arrive at their winged or most perfect state. The first state of these animals is in the caterpillar or reptile form; then they pass into the chrysalis-state, wherein they remain, immoveably fixed to one spot, and surrounded with a case or covering, which is generally of a conical figure; and, lastly, after spending the usual time in this middle state, they throw off the external case wherein they lay imprisoned, and appear in their most perfect and winged form of butterflies, or

CHRYSIS, or gold-fly, a genus of insects belonging to the hymenoptera order. There are seven species, of which the lucidula is one: it is beautified with the most splendid colours. The fore part of the head is green and gold, and the hinder of a bright azure. The thorax is azure and green: the abdomen is green and gold before, and of a coppery red behind. This species lives in holes of walls.

CHRYSITRIX, in botany, a genus of the diœcia order, in the polygamia class of plants. There is one species, a native of the Cape.

CHRYSOBALANUS, cocoa plum: a genus of the monogynia order, and icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. There is only one species, the chrysobalanus icaco, a native of the Bahama Islands and many other parts of America, but commonly grows near the sea. It rises with a shrubby stalk eight or nine feet high.

CHRYSOCOMIA, goldy-locks: a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There are thirteen species, the most remarkable of which are the linosyris and the cernua.

These are herbaceous flowering perennials, growing from one to two feet high, ornamented with narrow leaves, and compound floscular flowers of a yellow colour.

CHRYSOGONUM, a genus of the polygamia necessaria order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There is one species, a native of Virginia.

CHRYSOLITE. *Peridot* of Haüy. Topaz of the ancients, while our topaz is their chrysolite. Chrysolite is the least hard of all the gems. It is scratched by quartz and the file. Its crystals are well formed compressed prisms, of eight sides at least, terminated by a wedged form or pyramidal summit, truncated at the apex. Its primitive form is a right prism, with a rectangular base. It has a strong double refraction, which is observed in looking across one of the large sides of the summit and the opposite face of the prism. The lateral planes are longitudinally streaked. The colour is pistachio green, and other shades. External lustre splendent. Sp. gr. 3.4. Chrysolite comes from Egypt, where it is found in alluvial strata. It has also been found in Bohemia, and in the Circle of Bunzlau.

CHRYSOMELA, in zoology, a genus of insects of the order of coleoptera, there are 122 different species, denominated from the trees on which they feed, as the chrysomela of tansy, beech, alder, willow, &c.

CHRYSOPHYLLUM, the BULLY TREE: a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 43d order, viz. dumosæ. The corolla is campanulated, decemfid, with the segments alternately a little patent. The fruit is a ten-seeded berry. There are six species, natives of the West Indies. The most remarkable are:

1. The Chrysophyllum cainito, rises thirty or forty feet high.

2. Chrysophyllum glabrum, never rises to the height of the cainito, nor do the trunks grow to half the size.

CHRYSOPRASE. This mineral, which is found in several parts of Germany, is always amorphous. Its fracture is either even or inclined to the splintery, with very little lustre; its colour green; specific gravity 2.5.

CHRYSOPLENIUM, a genus of the digynia order, in the decandria class of plants; and in the natural method ranking under the 12th order, succulentæ. The calyx is quadrifid or quinquefid, and coloured; no corolla; the capsule birostrated, unilocular, and polyspermous. Its English name is golden saxifrage. There are two species, common in the northern parts of Europe.

CHURN, an implement for agitating cream or milk, so as to effect the production of butter. Some churns are made upright, of a tapering form, and are worked by means of a pole and cross: the former passing through a hole in the lid. These are pail or bell-churns. A great variety of churns are in use; but, in general, their formation evinces more ingenuity than practical knowledge

CHYLE. See ANATOMY.

CICADIA, the FROG-HOPPER, or flea-locust, a genus of insects belonging to the order of hemiptera. The beak is inflected; the antennæ are setaceous: the four wings are membranaceous and deflected; and the feet in most of the species, are of the jumping kind. The species are fifty-one. The larvæ of several of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants, in the midst of which they reside. It is in the midst of this foamy substance that the larva goes through its metamorphosis into a chrysalis and perfect insect.

CICCA, a genus of the tetrandria order, in the monoecia class of plants. The male calyx is tetraphyllous; there is no corolla; the female calyx triphyllus: no corolla; four styles; the capsule four-berried. There is one species, a shrub of the East Indies.

CICER, the *chick-pea*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. There is but one species, which produces peas shaped like the common ones, but much smaller. They are cultivated in Spain, where they are natives.

CICHORIUM, *succory*, a genus of the polygamia æqualis order, in the syngenesia class of plants; belonging to the 49th natural order, compositæ. There are three species, 1. Cichorium endivia, the common endive, which is both an annual and biennial plant, and used as a sallad. 2. Cichorium intibus, or wild succory, grows naturally by the side of roads and in shady lanes. It is good in scorbutic complaints. 3. Cichorium spinosum, with a prickly stalk, grows in Sicily and the islands of the Archipelago.

CICINDELA, the *sparkler*, in zoology, a genus of coleopterous insects, of which there are 14 species. The campestris or field sparkler is one of the most beautiful. The upper part of the body is of a bluish green colour and rough; the under side, legs, and antennæ, are gold and red. The eyes are prominent. The thorax is angular and narrower than the head. Both are of a green colour tinged with gold. This insect runs, as well as flies, with great swiftness. It is found in dry sandy places, especially in the beginning of spring The larvæ of all this genus live under ground, and are, as well as the perfect insects, very fierce, attacking and destroying all they can.

CICUTA, *water hemlock*, a genus of the order digynia in the pentandria class of plants, ranking in the natural method under the 45th order umbellatæ. There are three species, 1. Cicuta bulbifera; 2. Cicuta maculata; 3. Cicuta virosa. This last is the only one remarkable, and that for the poisonous qualities of its roots.

CIDER, is the name of a fermented liquor, which is made in England, in great quantities, from the expressed juice of apples. The apples should be mellow ripe, and gathered when perfectly dry. It was formerly supposed that "the worse the fruit the better the cider," but this opinion has been refuted. The best pippins make the best flavoured cider, and such as are duly ripe, will produce a proportionate increase both of the quantity and of the flavour.

When the apples are gathered, they are ground in a mill into what is termed pommage. This pulp is then conveyed into the cider-press when it is formed by pressure into a kind

of cake called the cheese. This is effected by laying hair cloths between the layers of pommage, till there is a pile of ten or twelve layers. The whole is then pressed till all the *must* or *juice* is squeezed from it. This juice is then passed through a coarse hair sieve, after which it undergoes the process of fermentation in vats. When the fermentation has ceased, the liquor is put into casks, and kept in a cool place during winter. The proper time for racking it off may be known by the brightness of the liquor; the discharge of the fixed air; and the appearance of a *thick crust* on its surface. About the beginning of March it will be bright and pure, and is then fit for final racking and bottling.

CIMEX, or *bug*, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum is inflected. The antennæ are longer than the thorax. The wings are folded together crosswise, the upper ones are coriaceous from their base towards their middle. The back is flat; the thorax margined. The feet are formed for running. The cimex lectularius, or house bug, is particularly acceptable to the palate of spiders in general, and is even sought after by wood bugs. Trials have been made of various methods of destroying house-bugs, with oil of turpentine, camphor, solutions of sublimate, &c.

CIMICIFUGA, in botany, a genus of the polyandria order, in the diœcia class of plants. The male calyx is almost pentaphyllous; there is no corolla; the stamina are 20 in number: the female calyx is almost pentaphyllous; no corolla: the stamina 20, and barren; the capsules from four to seven, polyspermous. There is but one species; it is a native of the Carpathian mountains. It has obtained the name of cimicifuga, or bugbane, from its property of driving away those insects.

CIMOLITE, a species of white earth, found in some of the Grecian islands, where it is used for whitening stuffs. It is mentioned by Pliny under the name of cimolia, and in more modern authors it is called cimolia terra. Colour pearl-grey; when exposed to the air it becomes reddish. Texture earthy, fracture uneven, opaque, does not stain, but adheres strongly to the tongue. It is soft, and broken with difficulty: specific gravity is 2.000; and it becomes white before the blow-pipe.

CINCHONA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those plants, the order of which is dubious. The corolla is funnel-shaped, with a woolly summit; the capsule inferior, bilocular, with a parallel partition. There are nine species.

CINERARIA, a genus of the class and order syngenesia polygamia superflua. The calyx is simple, many-leaved, equal; pappus simple; receptacle naked. There are 41 species, most of them ornamental plants, and natives of the Cape.

CINNABAR, an ore of mercury, consisting of that metal united with sulphur. The principal use of cinnabar, is in painting; in which art it is known under the name of vermilion.

CINNAMON. See Laurus.

CINQUE *Ports*, five havens that lie on the east part of England towards France, thus called by way of eminence, on account of their superior importance, as having been thought by our kings to merit a particular regard, for their preservation against invasions. Hence they have a particular policy, and are governed by a keeper, with the title of a lord warden of the Cinque Ports, which office belongs to the constable of Dover; and their representatives are called Barons of the Cinque

[illegible]se five ports are Dover, Hastings, Rom[illegible] Hythe, and Sandwich; to which Winchelsea and Rye have been since added.

CIPHER, denotes certain secret characters *used in writing letters that contain some secret*, not to be understood but by those between whom the cipher is agreed on. There are several kinds of ciphers according to Lord Bacon; as the simple, those mixed with nonsignificants, those consisting of two kinds of characters, wheel-ciphers, key-ciphers, word-ciphers, &c.

CIRCÆA, *enchanter's nightshade*, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. There are two species, one of which is a native of Britain, and the other of Germany. They are low herbaceous plants with white flowers.

CIRCLE, in geometry, a plane figure comprehended by a single curve line, called its circumference; in which right lines drawn from a point in the middle, called the centre, are equal to each other.

The area of the circle is found by multiplying the circumference by the *fourth part* of the diameter; or half the circumference by half the diameter.

Circles, and similar figures inscribed in them, are always as the squares of the diameters; so that they are in a duplicate ratio of their diameters, and consequently of their radii.

A circle is equal to a triangle, the base of which is equal to the periphery, and its altitude to its radius; circles therefore are ratio compounded of the peripheries and the radii.

To find the proportion of the diameter of a circle to its circumference. Find, by continual bisection, the sides of the inscribed polygon, till you arrive at a side subtending any arch, however small; this found, find likewise the side of a sim[illegible] circumscribed polygon; multiply each by [illegible] number of the sides of the polygon, by which you will have the perimeter of each. The ratio of the diameter to the periphery of the circle will be greater than that of the same diameter to the perimeter of the circumscribed polygon, but less than that of the inscribed polygon. The difference of the two being known, the ratio of the diameter to the periphery is easily had in numbers very nearly, though not justly, true. Thus Archimedes fixed the proportion at 7 to 22.

CIRCLES, *druidical*, in British topography, a name given to certain ancient inclosures, formed by rude stones, circularly arranged.

These, it is now generally agreed, were temples, and many writers think also places of solemn assemblies for councils or elections, and seats of judgment.

CIRCUIT, in law, signifies the journey, or progress, which the judges take twice every year, through the several counties of England and Wales, to hold courts and administer

justice, where recourse cannot be had to the King's courts at Westminster; hence England is divided into six circuits, viz. the home circuit, Norfolk circuit, Midland circuit, Oxford circuit, Western circuit, and Northern circuit. In Wales there are but two circuits, North and South Wales.

CIRCULATION *of the blood*, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart to all parts of the body by the arteries, and returned from the same parts to the heart by the veins.

CIRCUMFERENCE, the curve line which bounds a circle; and otherwise called a periphery, the boundary of a right-lined figure being expressed by the term perimeter. The circumference of every circle is supposed to be divided into 360 degrees. The angle at the circumference of a circle is double that at the centre.

CIRCUMFERENTOR, an instrument used by surveyors for taking angles. See SURVEYING.

CIRCUMSCRIBED *hyperbola*, one of Sir Isaac Newton's hyperbolas of the second order, that cuts its asymptotes, and contains the parts cut off within its own space.

CIRCUMSCRIBING, in geometry, denotes the describing a polygonous figure about a circle, in such a manner that all its sides shall be tangents to the circumference. Sometimes the term is used for the describing a circle about a polygon, so that each side is a chord; but in this case it is more usual to say the polygon is inscribed, than the circle is circumscribed.

CIRCUMVALLATION, or *line of circumvallation*, in the art of war, is a trench bordered with a parapet, thrown up quite round the besieger's camp, by way of security against any army that may attempt to relieve the place, as well as to prevent desertion. See FORTIFICATION.

CISSAMPELOS, a genus of the monadelphia order in the diœcia class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. There are three species.

CISSOID, in geometry, a curve of the second order, first invented by Diocles and called after his name.

CISSUS, the wild grape, a genus of the monogynia order in the tetrandria class of plants, ranking in the natural method under the 46th order, hederaceæ. There are 15 species, natives of Jamaica and some of the adjacent islands, also of some parts of the East Indies. The branches have tendrils at their joints by which they climb up trees to a considerable height.

CISTUS, the *rock rose*, a genus of the monogynia order, in the polyandria class of plants, ranking in the natural method under the 20th order, rotaceæ. There are 66 species, mostly natives of the southern parts of Europe. They are very beautiful evergreen shrubs, and very ornamental in gardens. The flowers are white, purple, and yellow. They are propagated by seeds or cuttings. Gum labdanum is obtained from one of the species in the Levant.

CITADEL, a place fortified with four, five, or six bastions, built on a convenient ground near a city, that it may command it in case of a rebellion.

CITHAREXYLUM, in botany, *English fiddle-wood*, a genus of the didynamia angiospermia class and order. Natural order of personatæ. There are five species; all natives of the West Indies.

CITRIC *acid*. Acid of limes. It has been found nearly unmixed, with other acids, not only in lemons, oranges, and limes, but also in the berries of *vaccinium oxycoccus*, or cranberry, *vaccinium vitis idæa*, or red whortleberry, of birdcherry, nightshade, hip, in unripe grapes and tamarinds. Gooseberries, currants, bilberries, beamberries, cherries, strawberries, cloudberries, and raspberries, contain citric acid mixed with an equal quantity of malic acid. The onion yields citrate of lime.

CITRUS, the citron, orange, and lemon tree a genus of the polydelphia class and the icosandria order of plants. The calyx is quinquefid; the petals oblong, and five in number; the antheræ are 20, filaments united into various bodies; fruit, nine-celled. There are five species, with many varieties, viz.

I. Citrus aurantium, the orange: of which the varieties are, 1. Seville orange. This is a very handsome tree, and the hardiest of any. The fruit is large, rough-rinded, and sour, of excellent quality for economical uses. 2. The China orange. This has a smooth, thin rind, sweet fruit, of which there are several varieties in warm countries. 3. The forbidden-fruit tree, very much resembles the common orange-tree; but the fruit is larger. 4. The horned orange is a tree of moderate size, producing fruit which divide, and the rind runs out into divisions like horns. 5. The hermaphrodite orange is a common sized tree, producing fruit shaped partly like an orange, and partly like a citron. 6. The dwarf orange tree, or nutmeg-orange, growing two or three feet high; the fruit is very small.

II. Citrus medica, the citron-tree. The varieties are, 1. Citron-tree with sour fruit 2. with sweetish fruit; 3. with long fruit, 4. with warted fruit; 5. with recurved fruit; and 6. with blotched leaves.

The lemon-tree is accounted a variety of the citron. Of this there are no fewer than eleven varieties.

These are the most remarkable varieties of the species of citrus; but besides these there are several others.

1. Citrus trifoliata, is a thorny shrub, growing naturally in Japan, where it is likewise known by the names of gees, and karatals banna.

2. Citrus decumana, or shaddock, which derives its name from captain Shaddock, who brought it from the East Indies.

3. Citrus japonica, the fruit of which is no larger than a cherry, but very sweet and pleasant.

CIVIL *law*, is properly the peculiar law of each state, country, or city; but what is usually meant by the civil law, is a body of laws composed out of the best Roman and Grecian laws, compiled from the laws of nature and nations, and for the most part received and observed throughout all the Roman dominions for about 1200 years.

In England it is used in the ecclesiastical courts, in the courts of the admiralty, and in

the two universities; yet in all these it is restrained and directed by the common law.

Civil *year* is the legal year, or annual account of time, which every government appoints to be used within its own dominions; and is so called in contradistinction to the natural year, which is measured by the revolution of the heavenly bodies.

CIVILIAN, in general, denotes something belonging to the civil law, but more especially the doctors and professors of it are called civilians. Of these we have a college or society in London, known by the name of doctors-commons.

CLAMP, *in a ship*, denotes a piece of timber applied to a mast or yard, to prevent the wood from bursting; and also a thick plank lying fore and aft under the beams of the second deck.

Clamp is likewise the term for a pile of unburned bricks, built up for burning.

CLAMPING, in joinery, is the fitting a piece of board with the grain, to another piece of board cross the grain to prevent its warping.

CLARIFICATION, is the separation, by chemical means, of any liquid from substances suspended in it, and rendering it turbid.

CLARINET, in music, a wind instrument of the reed kind, the scale of which, though it includes every semitone within its extremes, is virtually defective. Its lowest note is E, below the F cliff, from which it is capable, in the hands of good solo performers, of ascending more than three octaves.

CLARO *obscuro*, or Clair *obscure*, in painting, the art of distributing to advantage the lights and shadows of a piece, both with regard to the easing of the eye, and the effect of the whole piece.

CLASS, a term given to the general divisions of a subject: thus in the Linnæan system, animals and plants are divided into classes.

CLATHRUS, in botany, a genus of roundish fungi; the substance of which is full of holes, like the meshes of a net. There are 7 species.

CLAVARIA, *club top*, a genus of the cryptogamia class of plants, and of the order of fungi; and in the 58th of the natural method. According to Miller, the whole genus of clavaria ought to be reckoned in the tribe of the zoophytes; and therefore he classes them among the vermes. Other naturalists, however, have not been able to discern any thing of an animal nature in the clavaria. The species are: 1. Clavaria bemotades, or the oak leather club-top, resembling tanned leather. 2. Clavaria militaris.

CLAVICLES, in anatomy, are two bones situated transversely and a little obliquely opposite to each other, at the superior and anterior part of the thorax, between the scapula and sternum.

CLAUSE signifies an article, or particular stipulation, in a contract, a charge or condition in a testament, &c.

Thus we say, a derogatory clause, a penal clause, saving clause, codicillary clause, &c.

CLAY. The clays are opaque and non crystallized bodies, and of dull fracture. They form with water a plastic paste, possessing considerable tenacity, which hardens with heat, so as to strike fire with steel. Marles and chalks also soften in water, but their paste is not tenacious, nor does it acquire a siliceous hardness in the fire. The affinity of the clays for moisture is manifested by their sticking to the tongue, and by the intense heat necessary to make them perfectly dry. The odour ascribed to clays breathed upon, is due [illegible]he oxide of iron mixed with them. Absolutely pure clays emit no smell.

Of the different kinds of clay at present known, the following are the principal. 1. *Porcelain clay*, derived chiefly from the decomposition of feldspar, and containing silica and alumina, with traces of oxide of iron. 2. *Marl clay*, which contains a portion of carbonate of lime, and is much used in making pale coloured bricks. 3. *Pipe clay*, which is very plastic, requiring a high temperature for fusion, and used for tobacco-pipes and white pottery. 4. *Potters' clay*, which is of a reddish colour; it is used for coarse pottery, and, mixed with sand, for bricks and tiles.

CLAYTONIA, in botany, a genus of the pentandria monogynia class of plants, the flower of which consists of five erect, large petals; the fruit is a roundish unilocular capsule, containing three roundish seeds. There are two species.

CLEF, or Cliff, in music, a mark set at the beginning of a song, to shew the key in which the piece is to be performed; or it is a letter marked on any line which explains the rest.

CLEMATIS, virgin's bower, in botany, a genus of the polyandria polygynia class of plants, the flower of which consists of four oblong lax petals. There is no pericarpium, but a small receptacle contains several roundish seeds, crowned with a slender filament. There are 21 species, chiefly climbing shrubs.

CLEOME, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 25th order, putamineæ. There are 15 species; all natives of warm climates, except two. They are herbaceous plants, rising from one to two feet high; and are adorned with flowers of various colours.

CLEPSYDRA, a water-clock, or instrument to measure time by the fall of a certain quantity of water.

There wer[illegible]any kinds of clepsydræ among the ancients; but they all had this in common, that the water ran generally through a narrow passage, from one vessel to another; and in the lower was a piece of cork or light wood, which, as the vessel filled, rose up by degrees, and shewed the hour.

CLERK, a word originally used to denote a learned man, or man of letters: whence the term became appropriated to churchmen, who were from thence called clerks or clergymen; the nobility and gentry being usually bred up to the exercise of arms, and none left but the ecclesiastics to cultivate the sciences. The term is now applied to persons in different offices of the law and government, and also to those who keep merchants' accounts.

CLERODENDRUM, a genus of the didynamia angiospermia class of plants. There are eight species, natives of the East Indies.

CLETHRA, a genus of the monogynia order in the decandria class of plants, and in the

natural method ranking under the 18th order, bicornes. There are four species, of which the most remarkable is, clethra alnifolia, a native of Virginia and Carolina, where it grows in moist places, and near the sides of rivulets, rising near eight or ten feet high. This plant bears the open air in Britain, and is one of the most beautiful flowering shrubs. It is propagated by layers, but they are generally [illegible]o years before they take root.

CLIBADIUM, a genus of the monœcia pentandria class and order. There is only one species, a native of Surinam.

CLIFFORTIA, a genus of the polyandria order, in the diœcia class of plants: and in the natural method ranking under the 38th order, tricoccæ There are nineteen species, all natives of Africa; they require to be kept in a green-house when cultivated in this country.

CLIMATES, in geography, spaces upon the surface of the terrestrial globe, contained between two parallels, so far distant from each other, that the longest day on one parallel differs half an hour from the longest day on the other. See GEOGRAPHY.

CLINCH, in the sea-language, that part of a cable which is bent about the ring of the anchor, and then made fast.

CLINIC *medicine*, particularly used for the method of visiting and treating sick persons in bed, and the more exact discovery of all the symptoms of their disease.

CLINOPODIUM, *field-basil*, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 41st order, asperifoliæ. There are five species, all herbaceous plants, growing from one to two feet high.

CLITORIA, a genus of the decandria order in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. There are five species, all herbaceous perennials, or annuals, of the kidney-bean kind, growing naturally in both the Indies. The flowers, which are elegant, stand singly, each on its proper footstalk. They are large, and generally of a deep blue, but sometimes of a white colour.

CLOCK. See HOROLOGY.

CLOFF, that in which any goods are put for the convenience of carriage; as the bags of pepper or hops, the ba[illegible]ls of butter, soap, &c.

CLOUD. A mass of vapour, more or less opaque, formed and sustained at considerable heights in the atmosphere, probably by the joint agencies of heat and electricity. The first successful attempt to arrange the diversified forms of clouds, under a few general modifications, was made by Luke Howard, Esq. We shall give here a brief account of his ingenious classification.

The *simple* modifications are thus named and defined: 1. *Cirrus.* Parallel, flexuous, or diverging fibres, extensible in any or in all directions. 2. *Cumulus.* Convex or conical heaps, increasing upwards from a horizontal base. 3. *Stratus.* A widely extended, continuous horizontal sheet, increasing from below.

The *intermediate* modifications which require to be noticed are, 4. *Cirro-cumulus.* Small well-defined roundish masses, in close horizontal arrangement 5. *Cirro-stratus.* Horizontal, or slightly inclined masses, attenuated towards a part or the whole of their circumference, bent downward, or undulated, separate or in groups, consisting of small clouds having these characters.

The *compound* modifications are, 6. *Cumulo-stratus.* The cirro-stratus, blended with the cumulus, and either appearing intermixed with the heaps of the latter, or superadding a wide-spread structure to its base.

7. *Cumulo-cirro-stratus,* vel *Nimbus.* The rain cloud. A cloud or system of clouds from which rain is falling. It is a horizontal sheet, above which the cirrus spreads, while the cumulus enters it laterally and from beneath.

The *cirrus* appears to have the least density, the greatest elevation, the greatest variety of extent and direction, and to appear earliest on serene weather, being indicated by a few threads pencilled on the sky. Before storms they appear lower and denser, and usually in the quarter opposite to that from which the storm arises. Steady high winds are also preceded and attended by *cirrus* streaks, running quite across the sky in the direction they blow in.

The cumulus has the densest structure, is formed in the lower atmosphere, and moves along with the current next the earth. A small irregular spot first appears, and is, as it were, the nucleus on which they increase. The lower surface continues irregularly plane, while the upper rises into conical or hemispherical heaps; which may afterwards continue long nearly of the same bulk, or rapidly rise into mountains. They will begin, in fair weather, to form some hours after sunrise, arrive at their maximum in the hottest part of the afternoon, then go on diminishing and totally disperse about sunset. Previous to rain, the cumulus increases rapidly, appears lower in the atmosphere, and with its surface full of loose fleeces or protuberances. The formation of large cumuli to leeward in a strong wind, indicates the approach of a calm with rain. When they do not disappear or subside about sunset, but continue to rise, thunder is to be expected in the night. The *stratus* has a mean degree of density, and is the lowest of clouds, its inferior surface commonly resting on the earth or water. This is properly the cloud of night appearing about sunset. It comprehends all those creeping mists, which in calm weather ascend in spreading sheets, (like an inundation of water), from the bottom of valleys, and the surfaces of lakes and rivers. On the return of the sun, the level surface of this cloud begins to put on the appearance of cumulus, the whole at the same time separating from the ground. The continuity is next destroyed, and the cloud ascends and evaporates, or passes off with the appearance of the nascent cumulus. This has long been experienced as a prognostic of fair weather.

The *cirrus* having continued for some time increasing or stationary, usually passes either to the cirro-cumulus or the cirro-stratus, at the same time descending to a lower station in the atmosphere. This modification forms a very beautiful sky; is frequent in summer, an attendant on warm and dry weather. The *cirro-stratus*, when seen in the distance, frequently gives the idea of shoals of fish. It precedes

wind and rain; is seen in the intervals of storms; and sometimes alternates with the cirro-cumulus in the same cloud, when the different evolutions form a curious spectacle. A judgment may be formed of the weather likely to ensue by observing which modification prevails at last. The solar and lunar *halos*, as well as the parhelion and paraselene, (mock sun and mock moon,) prognostics of foul weather, are occasioned by this cloud. The cumulo-stratus precedes, and the nimbus accompanies rain.

CLUPEA, or *herring*, in ichthyology, a genus belonging to the order of abdominales. There are 11 species, of which the following are the principal.

1. The clupea harengus, or common herring, has no spots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water; whence the proverb, As dead as a herring. Herrings are found from the highest northern latitudes yet known, as low as the northern coasts of France. They are met with in vast shoals on the coast of America, as low as Carolina. The great winter rendezvous of the herring is within the arctic circle. An immense number of them begin to appear off the Shetland isles in April and May; but these are only the forerunners of the grand shoal which comes in June; and their appearance is marked by certain signs, by the numbers of birds which follow to prey on them.

The first check this army meets with in its march southward is from the Shetland isles, which divide it into two parts; one wing takes to the east, the other to the western shores of Great Britain, and fill every bay and creek with their numbers; the former pass on towards Yarmouth, the great mart of herrings; they then pass through the British Channel, and disappear. Those which go towards the west, proceed to the north of Ireland: here they meet with a second interruption, and are obliged to make a second division; one party going to the western side, and being soon lost in passing into the Atlantic, the other into the Irish sea.

They are full of roe in the end of June, and continue in perfection till the beginning of winter, when they deposit their spawn. The young herrings approach the shores in July and August, and are then from half an inch to two inches long.

2. The clupea sprattus, or sprat, has 13 rays in the back fin. It is a native of the European seas, and has a resemblance to the herring, but is smaller. The season for them is from November to March.

3. The clupea encrasiolus, or anchovy, has the upper jaw longer than the under one, and is about three inches long. They are taken in the Mediterranean, and brought here and pickled.

4. Clupea alosa, the shad, has a forked snout, and black spots on the sides. In Great Britain the Severn affords this fish in higher perfection than any other river. It makes its first appearance there in May, but in very warm seasons in April.

CLUYTIA, in botany, in memory of Augerius Clutius, professor of botany at Leyden, a genus of the dioecia gynandria class and order. Essential character: calyx five leaved; corolla five-petalled; female, styles three; capsule three-celled; seed one. There are 10 species, all natives of hot climates.

CLYPEOLA, in botany, a genus of the tetradynamia siliculosa class and order. Natural order of siliquosæ. Essential character: silicle emarginate, or biculate, compressed, flat, deciduous. There are three species. These are low plants that have little beauty, [illegible] are preserved chiefly in botanic gardens.

CLYSTER is a liquid remedy to be injected chiefly at the anus into the larger intestines.

CNEORUM, *widow wail*, a genus of the monogynia order, in the triandria class of plants, ranking in the natural method under the 38th order, tricoccæ. There is only one species, which is a small evergreen, and very ornamental shrub, with simple leaves and yellow flowers. It is propagated from seeds.

CNICUS, *blessed thistle*, a genus of the polygamia æqualis order, in the syngenesia class of plants, in the natural method ranking under the 49th order compositæ. There are nine species, of which the only one remarkable is that called carduus benedictus. It is an annual plant, and flowers in June and July. The leaves are bitter, and a strong decoction from this plant produces vomiting. It is now little used in medicine.

COAGULATION, in chemistry, the rendering a fluid body in some degree solid by exposure to cold, or by the addition of something by which it is decomposed.

COAK, a hard sonorous substance, the residue of coal when subjected to destructive distillation. It is properly charcoal containing the earthy ingredients of the coal, and the process of charring it is conducted after the same manner as that of wood. It is chiefly used by iron and brass founders, when an intense heat is required; also for smelting iron ore, and for operations in which smoke would be detrimental, as in the drying of malt, and in the manufacture of most articles of confectionary.

COAL. This very important order of combustible minerals, is divided by Professor Jameson into the following species and sub-species:—

Species 1. Brown coal.

Species 2. Black coal, of which there are four sub-species; slate coal, cannel-coal, foliated coal, and coarse coal.

1. *Slate coal.* Its colour is intermediate, between velvet-black, and dark greyish black. It has sometimes a peacock-tail tarnish. It occurs massive, and in columnar and egg-shaped concretions. It has a resinous lustre, principal fracture slaty; is brittle, burns longer than cannel coal; cakes more or less, and leaves a slag.

2. *Cannel coal.* Colour between velvet and greyish black. Massive. Resinous lustre; fracture flat conchoidal, or even. Hardness as in the preceding. Brittle It is found in different parts of England, and also in Scotland; and has been worked on the lathe into drinking vessels, snuff-boxes, &c.

3. *Foliated coal.* Colour velvet black, sometimes with iridescent tarnish. Massive, and in lamellar concretions. Resinous or resplendent lustre; softer than cannel coal; between brittle and sectile, and easily broken.

It occurs in the coal formations in this and other countries.

4. *Coarse coal.* Colour dark greyish black, inclining to brownish black. Massive, and in granular concretions. Glistening lustre; fracture imperfect scaly; hardness as above, and easily frangible. It occurs in the German coal formations.

Species 3d. *Glance coal,* of which the Professor gives two sub-species. *Pitch-coal,* and Glance-coal. 1. *Pitch-coal.* Colour, velvet black. Massive, or in plates and botroidal branches, with a woody texture. Splendent and resinous: fracture, large perfect conchoidal. Brittle; does not soil; burns with a greenish flame; occurs along with brown coal in beds, and is found in the isles of Sky and Faroe. It is used for fuel, and for making vessels and snuff-boxes.

2. *Glance-coal,* of which we have four kinds, conchoidal, slaty, columnar, [illegible] fibrous. The conchoidal has an iron-black colour, inclining to brown, with sometimes a tempered steel tarnish. Massive and vesicular. Splendent, shining, and imperfect metallic lustre. Fracture flat conchoidal; hardness as above; brittle and easily frangible; burns without flame or smell, and leaves a white ash.

Slaty glance coal. Colour, iron-black. Massive. Lustre, shining and imperfect metallic. Principal fracture, slaty; coarse fracture, imperfect conchoidal. It is found in Spain, in Switzerland, England, Scotland, and Ireland. In this country it is called blind coal.

Columnar glance coal. Colour, velvet-black, and greyish black. Massive, disseminated, and in prismatic concretions. Lustre, glistening, and imperfect metallic. Fracture, conchoidal; burns without flame or smoke, and is found in several parts of Scotland.

Fibrous coal. Colour, dark greyish-black. Massive, in thin layers, and in fibrous concretions. Lustre, glimmering, or pearly. It soils strongly, is soft, passing into friable; and burns without flame, but some varieties scarcely yield to the most intense heat. It is found in the different coal fields of Great Britain. Its fibrous concretions distinguish it from every other kind of coal.

COASTING, that part of navigation where the places assigned are not far distant, so that a ship may sail in sight of land, or within soundings between them. In this there is only required a good knowledge of the land, the use of the compass and lead, or sounding line.

COAT *of arms,* in heraldry, a surcoat reaching to the waist, open at the sides, and ornamented with armorial bearings, worn by the ancient knights in times of war, or at tournaments, over their armour, being the principal characteristic by which they were distinguished from one another, the face being covered with the helmet.

COATING, in chemistry, is used principally for the purpose of defending certain vessels from the immediate action of fire; thus, glass retorts, and the inside of some furnaces, are coated with various compositions.

COBALT. See CHEMISTRY.

COCCINELLA, in zoology, a genus of insects of the order of coleoptera. The females deposit their eggs, which turn to small larvæ, slow in their process, and enemies to the plant-louse. Of all the different larvæ of the coccinella, the most curious is the white hedgehog; a name given it on account of the singularity of its figure, and the tufts of hair which render it remarkable. After a fortnight it settles on one spot, and, without parting with its fur, turns to a chrysalis: three weeks after which it becomes a coccinella.

COCCOLOBO, a genus of the trigynia order, in the octandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There are 19 species: the most remarkable is that called the uvifera, or sea-side grape. It grows upon the sandy shores of most of the West India islands.

COCCULUS *Indicus,* the name of a poisonous berry, supposed to be used by brewers in their malt liquors, particularly in porter, to give it an intoxicating quality. But as the use of it is forbidden by the laws of the land, it would be unfair to impute the practice of it to any respectable house.

COCCUS, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum proceeds from the breast: the belly is bristly behind; the wings of the male are erect; and the female has no wings.

There are about fifty species of this insect, extremely fertile, and troublesome in hot houses and green houses. The most important species is the coccus cacti, a native of the warmer parts of America. This is the famous cochineal animal, so highly valued in every part of the world for the incomparable beauty of its red colour, which it readily communicates to wool and silk, but with much more difficulty to linen and cotton.

The cochineal insect may, in some circumstances, be compared to the silk-worm, particularly in the manner of depositing its eggs. The insects destined for this purpose are taken at a proper time of their growth, and put into a box well closed, and lined with a coarse cloth, lest any of them should be lost; and in this confinement they lay their eggs and die. The box is kept close till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a sufficient indication that the animalcule has life, though the egg is so minute as hardly to be perceived; and this is the seed placed on the foliage of the cactus cochenilifer, or Indian fig, known to the Spaniards by the name of nopal, the quantity contained in the shell of a hen's egg being sufficient for covering a whole plant.

COCHINEAL. See the preceding article.

COCHLEARIA, *scurvy-grass,* a genus of the siliculosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosa. The silicula is emarginated, turgid, and scabrous; with the valves gibbous and obtuse. There are eight species.

COCK. See PHASIANUS.

COCKET is a seal belonging to the King's Custom-house, or rather a scroll of parchment sealed and delivered by the officers of the customs to merchants, as a warrant that their merchandises are customed. It is also used for the office where goods, transported, were first entered and paid their custom, and had a cocket or certificate of discharge.

COCKPIT, in a man of war, a place on the

lower floor, or deck, abaft the main-capstan, lying between the platform and the steward's room, where are partitions for the purser, surgeon, and his mates.

COCKSWAIN, or **COXSON**, an officer on board a man of war, who has the care of the barge and all things belonging to it, and must be also ready with his crew to man the boat on all occasions: he sits at the stern of the boat and steers.

COCOS, in botany, a genus belonging to the natural order of palmæ. It is of the monœcia hexandria class. There are five species, the principal is,

Cocos nucifera, the cocoa-nut tree. It frequently rises 60 feet high. The body of the trunk, generally leans to one side, occasioned by the great weight of nuts it sustains when young. The leaves or branches are often 14 or 15 feet long, about 28 in number, of a yellow colour, straight and tapering. When the kernel begins to grow, it incrusts the inside of the nut with a bluish, jelly-like substance: this hardens as it increases, and becomes as white as snow, and of the flavour of a filberd. The quantity of liquor in a full-grown nut is frequently a pint and upwards. The husky tegument of the nut consists of strong, tough, stringy filaments, which resemble coarse oakum. The leaves are wrought into brooms, hammocks in form of nets, mats, sacks, and other useful utensils.

COD. See GADUS.

CODE, a collection of the laws and constitutions of the Roman emperors, made by order of Justinian. The code is accounted the second volume of the civil law, and contains 12 books.

CODICIL. See WILL.

COEFFICENTS, in algebra, such numbers, or given quantities, as are put before letters, or unknown quantities, into which letters they are supposed to be multiplied. See ALGEBRA.

CŒLIAC *Artery*. See ANATOMY.

COFFEA, the *coffee-tree:* a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 47th order, stellatæ. There are 10 species, but that which is most worthy of attention is a native of Arabia Felix. The coffea Arabica seldom rises more than 16 or 18 feet in height; the main stem grows upright, and is covered with a light-brown bark; the branches are produced horizontally and opposite, crossing each other at every joint. The leaves also stand opposite; and when fully grown are about four or five inches long, and two broad in the middle, decreasing towards each end; the borders are waved, and the surface is of a lucid green. The flowers are produced in clusters at the root of the leaves, sitting close to the branches; they are of a pure white, and have a grateful odour. The fruit resembles a cherry. It grows in clusters, and is ranged along the branches under the axillæ of the leaves.

The coffee-tree is cultivated in Arabia, Persia, the East Indies, the isle of Bourbon, and several parts of America. It is also raised in botanic gardens in several parts of Europe.

COFFER, in fortification a hollow lodgment athwart a dry moat, from six to seven feet deep, and from sixteen to eighteen broad, the upper part being made of pieces of timber, raised two feet above the level of that moat, which little elevation has hurdles, laden with earth, for its covering, and serves as a parapet with embrasures.

COHESION, or attraction of cohesion, is that power by which the particles of bodies are held together. The absolute cohesion of solids is measured by the force necessary to pull them asunder. Heat is excited at the same time. At the iron cable manufactory of Captain Brown, a cylindrical bar of iron, 1¼ inch diameter, was drawn asunder by a force of 43 tons. Before the rupture, the bar lengthened about five inches, and the section of fracture was reduced nearly three-eighths of an inch. About this part a degree of heat was generated, which, according to Mr. Barlow of Woolwich, rendered it unpleasant, if not in a slight degree painful, to grasp the bar in the hand. The same thing is shewn in a greater degree in wire-drawing. When the force is applied to compress the body, it becomes shorter in the direction of the force, which is called the *compression:* and the area of its section at right angles to the force, expands. The cohesion, calculated from the transverse strength, is as near, or perhaps nearer, the real cohesion, than that obtained by pulling the body asunder. The cohesive force of metals is much increased by wire-drawing, rolling, and hammering them.

COINING, or COINAGE, is the making of the metallic currency of the country. The method of conducting this process in the Royal Mint has, within the last few years, undergone a complete reformation.

The machinery, which is the invention of Messrs. Bolton and Watt, Morrison, Barton and others, is, for the most part, worked by steam; and is so constructed as to secure the principles of economy, accuracy, and despatch, in an astonishing degree.

The newly constructed melting furnace of Mr. Morrison, it is said, is capable of melting, with ease, 10,000 lbs. troy of silver daily; this was done for several months, during the recoinage, in 1817. The beautiful invention of Mr. Barton for reducing the plates, out of which the blanks are to be cut, to a uniform thickness, has entirely superseded the old tedious, and clumsy process of filing each individual blank to the standard weight. But the most ingenious piece of the mint machinery is the coining press.

This press is worked by means of a series of machinery placed in an apartment over the coining room, and connected with the steam engine. It has adapted to it a contrivance by which it feeds itself with the blanks to be impressed, and removes them the instant they have received the impression; while at the same time it acts as a register, and keeps an unerring account of the number of pieces struck. There are eight of these presses fixed in the coining room; and by the aid of this new machinery, four boys are capable of striking 20,000 pieces of money in an hour.

COIX, *Job's tears*. a genus of the triandria order, in the monœcia class of plants; and in the natural method ranking under the 4th order, gramina. There are three species, the principal of which the coix lacryma, is a native

of the East Indies, and frequently cultivated in Spain and Portugal.

COLCHICUM, meadow saffron: a genus of the trigynia order, in the hexandria class of plants, and in the natural method ranking under the 9th order, spathaceæ.

There are three species; all bulbous-rooted perennials, possessing the singular property of their leaves appearing at one time, and their flowers at another.

COLD. When caloric combines with our bodies, or separates from them, we experience, in the first case, the sensation of heat, in the second, cold. When the hand is put upon a hot iron, part of the caloric leaves the iron, and enters the hand; this produces the sensation of heat. On the contrary, when the hand is put upon a lump of ice, the caloric rapidly leaves the hand and combines with the ice; this produces the sensation of cold. The sensation of heat is occasioned by caloric passing into our bodies; the sensation of cold by caloric passing out of our bodies. We say that a body is hot, when it communicates caloric to the surrounding bodies; we call it cold, when it absorbs caloric from other bodies.

The opinion that cold is a real substance seems to have gained considerable ground from the experiments of the members of the Academy del cimento at Florence, which were afterwards revived by Pictet of Geneva, with perfect success. But the concentration of cold in the focus of a speculum; although it appears to establish, or at least to render probable, the distinct and material existence of cold, is accounted for by modern philosophers on a different principle. The true solution of this problem is derived from the abstraction of that return of heat which the thermoscope mirror had derived from the one which is operated on by the cooling body, and now participating in its radiating tension. Thus, also, a black body placed in the focus of one mirror, would diminish the light in the focus of another; the eye, according to Sir H. Davy, being to the rays producing light, a *measure* similar to that which the thermometer is to rays producing heat. See Congelation.

COLDENIA, a genus of the tetragynia order, in the tetrandria class of plants; and in the natural method ranking among those of the dubious order. There is but one species, a native of India.

COLEOPTERA, among zoologists, the first order of insects, comprehending all those with four wings, the external pair of which are hard, rigid, and opake, and form a kind of case for the interior pair: the mouth consists of two transverse jaws.

According to the Linnæan system, there are about 56 genera in this order.

COLIC, in medicine, a severe pain in the lower venter, so called, because the disorder was formerly supposed to be seated in the colon.

COLISEUM, or Colisæum, in ancient architecture, an oval amphitheatre at Rome, built by Vespasian, wherein were statues set up, representing all the provinces of the empire: in the middle of which stood that of Rome, holding a golden apple in her hand.

COLLEGE, an assemblage of several bodies or societies, of several persons into one society. Among the Romans there were the colleges of augurs, managers of the public games, carpenters, potters, lock-smiths, engineers, butchers, bakers, and tent makers; each of which had its distinct hall, or place of meeting.

COLLIERS, vessels employed to carry coals from one port to another, principally from the northern parts of England to the capital, and more southern parts, and foreign markets. Their trade is known to be an excellent nursery for seamen.

COLLINSONIA, in botany, a genus of the diandria monogynia class and order. Leaves, ovate, glabrous; stem glabrous. Two species, found in North America.

COLLYRIUM, in pharmacy, a topical remedy for disorders of the eyes.

COLOGNE *earth*, a substance used in painting, much approaching to amber in its structure, and of a deep brown. It has generally been esteemed a genuine earth, but has been discovered to contain a great deal of vegetable matter, and, indeed, is a very singular substance.

COLON, in anatomy, the second of the three large intestines.

Colon, in grammar, a character marked thus, (:) to divide a sentence.

COLONEL, in military matters, the commander-in-chief of a regiment, whether horse, foot, or dragoons.

Colonel, *lieutenant*, the second officer in a regiment, who is at the head of the captains, and commands in the absence of the colonel.

COLONNADE. See Architecture.

COLONY. A colony is a settlement formed by the inhabitants of any nation in some part of the world, unoccupied by any other civilized nation.

COLOPHONY. Colophony, or black resin, is the resinous residuum after the distillation of the light oil, and thick dark reddish balsam, from turpentine.

COLOSSUS, a statue of a gigantic or enormous size. The most famous of this kind was the colossus of Rhodes, made in honour of Apollo, by Chares the disciple of Lysippus. It was 86 feet high, and its thumb so large that few people could embrace it. This statue was placed across the mouth of the harbour at Rhodes, and the ships, in full sail, passed betwixt its legs.

COLOURS, in optics. See Optics.

Colours, in painting. See Painting.

Colours, in heraldry, are red, blue, black, green, and purple, thus distinguished: gules, azure, sable, vert, and purpule; yellow and white called or and argent, are metals.

COLUBER, a genus of serpents. The generic character is, scuta or undivided lamellæ under the abdomen, broad alternate scales under the tail. There are 97 species, the principal of which are: 1. Coluber Berus, or the viper, whose general length is about 18 to 24 inches, though some have been found near three feet; the fangs, which are usually two, are placed on each side the fore part of the upper jaw. The remedy for the bite of the viper, is olive oil, thoroughly rubbed on the wounded part, and about a wine glass full taken internally. The viper is viviparous, and

produces its young towards the close of the summer. It is asserted, that the female admits her young down her throat on sudden surprises.* 2. The cerastes, or horned viper, grows to the length of 12 or 15 inches. It has a pair of horns above the eyes, and is a native of the desarts of Africa, Syria, and Arabia. The general colour is a yellow or reddish brown, with large spots, and the belly of a pale lead colour. 3. Coluber nasicornis, or horned-nose snake, is a native of the interior of Africa, and its bite produces speedy death. It has two horns on the anterior part of the upper jaw. 4. Coluber naja, or cobra de capello, is a native of India, and about the length of three or four feet. The Portuguese call it cobra de capello, or hooded snake, from its appearance when irritated, when it bends the head downward, and seems hooded by the expanded skin of the neck. The Indians deprive it of its fangs, and then carry it about in a basket, making it dance to the sound of music. 5. Coluber aquaticus, or water viper, called in Carolina the water rattle snake, is a large animal, and its bite mortal. It frequents the water, and in summer numbers are seen lying on the branches of trees, watching for birds or fish. 6. Coluber argus, or argus snake, is a large species, above five feet in length. The head is covered with scales, and the teeth are large. The upper part of the animal is of a dusky chesnut colour, and the scales are marked with white specks: the whole body being beautifully marked with transverse rows of red spots. It is a native of Arabia. 7. Coluber natrix, or ringed snake, is common in this country, frequenting woods, moist hedges, and shady places. The general colour is a bluish grey, or pale olive on the upper parts, marked along the sides by black streaks. It is inoffensive, and feeds on frogs, mice, insects, worms, &c. It deposits its eggs in any warm and moist situation in the form of a chain to the number of twelve, fourteen, sixteen, or more. 8. Coluber atrovirens or French snake, is a harmless animal, and nearly resembles the preceding. 9. Coluber constrictor, or black snake is nearly six feet long, and all over of a shining black. It is very useful in killing rats, which it will follow to the tops of houses. It is a native of North America. 10. Coluber austriacus or smooth snake, is found in France and several other parts of Europe, and is very fierce, though the bite is harmless. 11. Coluber gemmatus, or bogle snake is a beautiful species, about sixteen inches long; the colour of the upper parts is blue, with three narrow stripes from head to tail; the two lateral stripes white, and the middle one black, with a row of small white specks resembling a string of beads. 12. The coluber mycterizans, or long-snouted snake, is of a green colour with a yellow line on each side the abdomen. It is about three feet long and about half an inch in diameter. It is a native of North America and feeds on insects. 13. Coluber ahætulla, or iridescent snake, is in general of a blue-green gilded appearance, accompanied by iridescent hues. The length is about three feet and a half, and about three quarters of an inch in diameter. It is a native of India.

COLUMBA, in ornithology, the pigeon, a genus belonging to the order of passeres. There are about 70 species, natives of different countries. The following are the most remarkable:

1. Columba coronata, or great crowned pigeon, about the size of a turkey. The bill is black, and the body of a cinereous blue colour. This species inhabits the Molucca isles and New Guinea, and has been brought to England alive.

2. Columba Malaccensis, the Malacca pigeon is little larger than the house-sparrow. It is a most beautiful species, and the flesh is said to be extremely delicate.

3. Columba migratoria, or pigeon of passage, is about the size of an English wood-pigeon; the bill black: it is red; the head of a dusky blue; the breast and belly of a faint red; above the shoulder of the wing there is a patch of feathers shining like gold; the wing is coloured like the head, having some few spots of black, the tail is very long, and covered with a black feather, under which the rest are white; the legs and feet are red. They come in prodigious numbers from the north to winter in Virginia and Carolina.

4. Columba œnas, or the domestic pigeon, and all its varieties, derive their origin from one species, the stock dove; the English name implying its being the stock or stem, whence the other domestic birds have sprung. It is of a deep bluish ash-colour; the breast dashed with a fine changeable green and purple. The varieties produced from the domestic breed are numerous, and elegant; they are distinguished by names expressive of their several properties, as tumblers, carriers, jacobines, croppers, pouters, runts, turbites, owls, nuns, &c. The most celebrated of these, is the carrier. They are gregarious; lay only two eggs, and breed many times in the year.

5. Columba palumbus, the ring dove or wood pigeon, is a native of Europe and Asia. It is the largest pigeon we have, and might be distinguished from all others by its size alone. The head, back, and covers of the wings, are of a bluish ash-colour; the lower side of the neck and breast are of a purplish red, dashed with ash-colour. This species forms its nest of a few dry sticks in the boughs of trees.

6. Columba passerina, or the ground-dove of Carolina, is about the size of a lark. They fly in great numbers together, and make short flights from place to place, generally lighting on the ground.

7. Columba turtur, or turtle-dove, is a native of India. The irides are of a fine yellow, and the eye-lids encompassed with a beautiful crimson circle. They are very shy, and breed in thick woods, generally of oak; in autumn they migrate into other countries.

COLUMN, in the military art, a long deep file of troops or baggage. The first and second lines of the army as they are encamped, make generally two columns on a march, filing off either from the right or left: sometimes the army marches in four, six, or eight columns, according as the ground will allow: and each column is led by a general officer.

COLUMN. See ARCHITECTURE.

COLUMNEA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There are six species, natives of the East and West Indies.

COLURES, in astronomy and geography

two great circles supposed to intersect each other at right angles in the poles of the world, and to pass through the solstitial and equinoctial points of the ecliptic.

COLUTEA, bastard sena; a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. There are nine species, deciduous flowering shrubs, adorned with many lobed leaves, and butterfly-shaped flowers, of a deep yellow or red colour. They are propagated both by seeds and layers.

COLYMBUS, *diver*, in ornithology, a genus of anseres. This genus includes several species, viz. the divers, guillemots, and grebes; of which the following are the most remarkable.

1. The grylle, or black guillemot, is in length fourteen inches, in breadth twenty-two; the bill is an inch and a half long, straight, slender, and black; the inside of the mouth red; on each wing is a large spot of white. Except in breeding-time, the grylle keeps always at sea; and is very difficult to be shot, diving at the flash of the pan.

2. The troile, or foolish guillemot, weighs 24 ounces; its length is 17 inches, the breadth 27½; the bill is three inches long, black, straight, and sharp pointed; the inside of the mouth yellow; the feathers on the upper part of the bill are short and soft like velvet; from the eye to the hind part of the head is a small division of the feathers; the rest is of a deep mouse-colour. They are found in the northern parts of Scotland, and the cliffs about Scarborough.

3. The septentrionalis, or red-throated diver, is more elegantly shaped than the others. It weighs three pounds. This species breeds in the northern parts of Scotland, on the borders of the lakes.

4. The glacialis, or northern diver, is three feet five inches in length; the breadth four feet eight. This species inhabits several parts of the north of Europe, but it is not often seen on land. The natives of Greenland use the skins for clothing; and the Indians about Hudson's Bay adorn their heads with circlets of their feathers.

5. The immer, or ember-goose, is superior in size to a common goose, and of a dusky colour. This species inhabits the Orkney islands; it is found also in most parts of the north of Europe, and in Switzerland

6. The Chinese diver, supposed to inhabit China. From the various and uncertain accounts of authors, it is not clear what birds the Chinese use for catching fish: the custom, however, of doing it, is manifest, from the relations, of many travellers. The bird used for this purpose has a ring fastened round the middle of the neck, in order to prevent its swallowing: besides this it has a slender long string fastened to it; and, thus accoutred, is taken by its master into his fishing-boat, from the edge of which it is taught to plunge after the fish as they pass by.

7. The cristatus, crested diver, or cargoose, weighs two pounds and a half. Its length is 21 inches, the breadth 30. The cheeks and throat are surrounded with a ruff, of a bright tawny colour, edged with black; the chin is white; the breast and belly are of a silvery white: the outside of the legs are dusky; the inside of a pale green. They frequent the fenny parts of the country, and in Lincolnshire they are called gaunts.

8. The urinator, or tippet-grebe, is somewhat less than the preceding, and is without the crest and ruff. This species is rather scarce in England, but is common in the winter time on the lake of Geneva.

9. The horned grebe is about the size of a teal; weight, one pound; length, one foot; breadth, sixteen inches. It inhabits Hudson's Bay; and first appears in May, about the fresh waters.

COMA *Berenices*, Berenice's hair, in astronomy, a constellation of the northern hemisphere, composed of stars near the lion's tail.

COMARUM, *marsh-cinquefoil*: a genus of the polygamia order, in the icosandria class of plants; and in the natural method ranking under the 35th order, senticosæ. There is but one species, a native of Britain. It grows to the height of about two feet, and the fruit resembles the straw berry.

COMB, an instrument to clean, untangle, and dress, flax, wool, hair, &c. Combs for wool are prohibited to be imported into Britain.

COMB, in a ship, a little piece of timber set under the lower part of the beakhead, near the middle

COMBINATION. The intimate union of the particles of different substances by chemical attraction, so as to form a compound possessed of new and peculiar properties.

COMBINATIONS, in mathematics, denote the alterations or variations, of quantities, letters, sounds, or the like, in all possible ways.

Of the doctrine of Combinations.

1. *When only two are combined.*—One thing admits of no combination. Two, *a* and *b*, admit of only one, viz. *ab*. Three *a*, *b*, *c*, admit of three, *ab*, *ac*, *bc*. Four of six, viz. *ab*, *ac*, *ad*, *bc*, *bd*, *cd*. Five of ten, viz, *ab*, *ac*, *ad*, *ae*, *bc*, *bd*, *be*, *cd*, *ce*, *de*.

Whence the numbers of combinations of two and two only, proceed according to the triangular numbers, 13, 6, 10, 15, 21, &c. which are produced by the continual addition of the original series, 0, 1, 2, 3, 4, 5, &c. And if n be the number of things, the formula for expressing the sum of all their combinations by two's, will be $\frac{n . n-1}{1 . 2}$

Thus, if $n=2$; this becomes $\frac{2 . 1}{\cdot}=1.$

If $n=3$; it is $\frac{3 . 2}{} =3.$

If $n=4$, $\frac{4 . 3}{2} =6$, &c.

2. *When three are combined together.* Three things admit of one order, *a*, *b*, *c*. Four admit of four, viz. *abc*, *abd*, *acd*, *bcd*. Five admit of ten; *abc*, *abd*, *abe*, *acd*, *ace*, *ade*, *bcd*, *bce*, *bde*, *cde*. And so on, according to the first pyramidal numbers, 1, 4, 10, 20, &c. which are formed by the continual addition of the former, or the triangular numbers, 1, 3, 6, 10, &c. And the general formula for any number of combinations, taken by three's is $\frac{n . n-1 . n-2}{1 \quad 2 . \quad 3}$

So, if $n=3$; it is $\frac{3 . 2 . 1}{1 . 2 . 3.}=1$

If $n=4$; it is $\frac{4 . 3 . 2}{6}=4$.

If $n=5$; it is $\frac{5 . 4 . 3 .}{6}=10$.

Proceeding thus, it is found that a general formula for any number n of things, combined by m at each time, is $s =$ $\frac{n}{1} . \frac{\overline{n-1}}{2} . \frac{\overline{n-2}}{3} . \frac{\overline{n-3}}{4}$, &c. continued to m factors or terms, or till the last factor in the denominator be m.

So, in six things, combined by four's, the number of combinations, is

$$\frac{6 . 5 . 4 . 3}{1 . 2 . 3 . 4}=15.$$

3. By adding these together, the sum will be the whole number of possible combinations of n things combined by two's, three's, four's, &c. And all the series, are the co-efficients of the power n of a binomial, wanting only the first two, 1 and n; therefore the sum will be $\overline{1+1}|^{2}-n-1$, or, 2^n-n-1. If the number of things be five then $2^5-6=32-6=26$.

II. *To find the number of changes and alterations which a number of quantities can undergo, when combined in all possible varieties of ways, with themselves and each other, both as to the things themselves, and their order and position.*

One thing admits of one order or position.

Two may be varied four ways, as *aa*, *ab*, *ba*, *bb*.

Three quantities taken by two's may be varied nine ways, as *aa*, *ab*, *ac*, *ba*, *ca*, *bb*, *bc*, *cb*, *cc*.

In like manner four things taken by two's may be varied 4^2 or 16 ways; and five things, by two's, 5^2 or 25 ways.

Thus also when taken by three's the changes will be n^3 and when taken by four's, they will be n^4 and so generally when taken by n's they will be n_n, wherefore adding all those together, the whole number of changes or combinations in n things taken by two's, by three's, by fours, &c. to n's, will be the sum of the geometrical series, $n+1^2+n^3+n^4$, which sum is $=$

$$\frac{n^n-1}{n-1}\times n$$

For example, if the number of things n be four; this gives

$$\frac{4^4-1}{4-1}\times 4=\frac{255}{3}\times 4=340.$$

COMBUSTION. The disengagement of heat and light which accompanies chemical combination. It is frequently made to be synonymous with inflammation, a term which might be restricted, however, to that peculiar species of combustion in which gaseous matter is burned. Ignition is the incandescence of a body, produced by extrinsic means, without change of its chemical constitution.

Although the subject of combustion is incontrovertibly one of the most striking and interesting of chemical phenomena, it is impossible to enter at large on it in this place. We shall therefore simply offer the opinion of Sir H. Davy, as given in Dr. Ure's Chemical Dictionary, which is stated in terms as concise as they are luminous. After adverting to the theories of former writers, which he clearly shews to be incorrect, he adds:—

From the preceding facts, it is evident, 1st, *That combustion is not necessarily dependent on the agency of oxygen*; 2d, That the evolution of the heat is not to be ascribed simply to a gas parting with its latent store of that ethereal fluid, on its fixation or combustion; and, 3dly, That no peculiar substance or form of matter is necessary for producing the effect, but that it is a *general* result of the actions of any substances possessed of strong chemical attractions, or different electrical relations, and that it takes place in all cases in which an intense and violent motion can be conceived to be communicated to the corpuscles of bodies.

All chemical phenomena indeed may be justly ascribed to motions among the ultimate particles of matter, tending to change the constitutions of the mass.

COMET, an opaque, spherical, and solid body, like a planet, performing revolutions about the sun in elliptical orbits, which have the sun in one of the foci. See ASTRONOMY.

COMETARIUM, a curious machine exhibiting an idea of the revolution of a comet about the sun. It is contrived in such a manner, as by elliptical wheels to shew the unequal motion of a comet, in every part of its orbit.

COMETES, a genus of the pentandria monogynia class and order. There is one species, a native of Suratte.

COMMA, among grammarians, a point or character marked thus (,); serving to denote a short stop, and to divide the members of a period.

COMMENSURABLE, among geometricians, an appellation given to such quantities as are measured by one and the same common measure.

COMMENSURABLE *numbers*, whether integers or fractions, are such as can be measured or divided by some other number, without any remainder: such are 12 and 18, as being measured by 6 or 3.

COMMERCE, the exchange of commodities for other articles, or for some representative of value for which other commodities can be procured. See TRADE.

COMMISSARY *general of the musters*, an officer appointed to muster the army, as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact account of the strength of the army.

COMMISSARY *general of stores*, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

COMMISSARY *general of provisions*, an officer who has the inspection of the bread and provisions of the army.

COMMITTEE *of Parliament*, a certain number of members appointed by the House for the examination of a bill, making report of an inquiry, process of the House, &c. When a Parliament is called, and the speaker and members have taken the oaths, there are committees appointed to sit on certain days, *viz.* the committee of privileges and elections, of religion, of trade, &c. which are standing committees. Sometimes the whole House resolves itself into a committee, on which occasion each person has a right to speak and reply as often as he pleases, which is not the case when a house is not in a committee.

COMMODORE, in maritime affairs, an officer of the British navy, commissioned by the lords of the admiralty, or by an admiral, to command a squadron of men-of-war in chief.

COMMON, is a right or privilege which one or more persons claim to take or use, in some part or portion of that, which another man's lands, waters, woods, &c. naturally produce; without having an absolute property in such lands, woods, waters, &c. 2 Inst. 65.

COMMON-*place book* is a sort of register, or orderly collection of things worthy to be noted, and retained in the course of a person's reading; and so disposed, as that among a multiplicity of subjects, any one may be easily found.

COMMON-*pleas*, one of the king's courts held in Westminster Hall, wherein a lord chief justice, and three puisne justices preside. In personal and mixed actions, it has a concurrent jurisdiction with the court of king's bench; but has no cognizance of pleas of the crown.

* **COMPANY**, a society of merchants, tradesmen, or others, united in one common interest. When there are only two, three, or four thus associated, it is called a partnership; the word company being usually restrained to a considerable number of members associated by prescription or charter. The mechanics of all towns incorporated are thus formed into companies, which have charters of privileges and immunities. In London they are numerous, and many of them are very rich. In a commercial sense the term company denotes a large association formed for the purpose of trade; thus we have the Hamburgh company which is the oldest trading establishment in the kingdom, being incorporated in 1295; the Russia company confirmed by charter in 1566; the Eastland company settled in 1579; the Turkey or Levant company in 1581, and confirmed with new privileges in 1605; the company of merchants trading to Africa, established in 1750; the South Sea company, formed in the reign of Queen Anne; the East India company, originally established in 1606; and lastly, the Hudson's Bay company, first chartered in 1670.

Company, in the army, a body of foot commanded by a captain, who has under him a lieutenant and an ensign: the number of men is from 50 to 80.

COMPARATIVE *anatomy*, is the science which examines the structure of the body in animals. It includes, in its most extensive sense, a view of the corporeal organization of all classes in the animal kingdom. This science is termed comparative anatomy, not because it stands in contradistinction to human anatomy, but because, while it embraces the whole circle of animal existence, it considers man as the standard of all its comparisons, and the primary object of all its inquiries.

The importance of this science to the anatomical student, and to the student of natural history must be obvious; since it would be absurd to found any system of physiological reasoning on the structure of any single animal or class; while the strongest interest is excited, and the highest degree of satisfaction obtained by this universal survey. We are indebted to such investigations for the discovery of the circulation of the blood, and of the lymphatic system; and there is certainly much truth in the observation of Haller, that "physiology has been more illustrated by comparative anatomy, than by the dissection of the human body." The student who is desirous of entering on this most interesting and instructive subject, will reap much advantage from the perusal of the compendious and scientific view of it published by Blumenbach, and translated into the English language by Dr. Lawrence.

Comparative *degree*, among grammarians; that between the positive and superlative degrees, expressing any particular quality above or beneath the level of another.

COMPARISON *of ideas*, among logicians, that operation of the mind whereby it compares its ideas one with another, in regard of extent, degree, time, place, or any other circumstance, and is the ground of relations.

Comparison, in rhetoric, a figure that illustrates and sets off one thing, by resembling and comparing it with another, to which it bears a manifest relation and resemblance, as the following figure in Shakspeare:

"She never told her love,
But let concealment, like a worm i' the bud,
Feed on her damask cheek: she pined in
thought,
And sat like Patience on a monument,
Smiling at Grief."

COMPARTMENT, or **Compartiment**, in general, is a design composed of several different figures, disposed with symmetry, to adorn a parterre, a ceiling, &c.

COMPASS, or *mariner's compass*, an instrument whereby the ship's course is determined. See Magnetism.

Compasses, or *pair of compasses*, a mathematical instrument for describing circles, measuring figures, &c. They consist of two sharp-pointed branches or legs of iron, steel, brass, or other metal, joined at top by a rivet, whereon they move as on a centre.

COMPLEMENT, in astronomy, the distance of a star from the zenith: or the arch comprehended between the place of the star above the horizon and the zenith.

Complement, in geometry, is what remains of a quadrant of a circle, or of 90°, after any certain arch has been taken away from it. Thus, if the arch taken away be 40°, its complement is 50: because 50+40=90. The sine of the complement of an arch is called the cosine, and that of the tangent, the cotangent, &c.

Complements in a parallelogram, are the two smaller parallelograms made by drawing two right lines through the diagonal, and parallel to the sides of the parallelogram. In every parallelogram, these complements are equal.

COMPLEX *terms*, or ideas, in logic are such as are compounded of several simple ones. Complex ideas, however compounded and recompounded, though their number is infinite, and their variety endless, may be all reduced under these three heads, modes, substances, and relations.

Complex proposition, is either that which has at least one of its terms complex; or such as contains several members, as causal propositions; or it is several ideas offering themselves to our thoughts at once, by which we are led to affirm the same thing of different

objects. Thus, God is infinitely wise, and infinitely powerful.

COMPLEXUS, in anatomy, a broad and pretty long muscle, lying along the back-part and side of the neck.

COMPOSITE ***numbers***, are such as can be measured exactly by a number exceeding unity; as 6 by 2 or 3, or 10 by 5, &c. so that 4 is the lowest composite number. Composite numbers between themselves, are those which have some common measure besides unity; as 12 and 15, as being both measured by 3.

Composite *order*. See Architecture.

COMPOSITION, in grammar, the joining of two words together; or prefixing a particle to another word, to augment, diminish, or change its signification.

Composition, in logic, a method of reasoning, by which we proceed from some general self-evident truth, to other particular and singular ones.

Composition, in music, the art of disposing musical sounds into airs, songs, &c. either in one or more parts, to be sung by a voice, or played on instruments.

Composition, in commerce, a contract between an insolvent debtor and his creditors, by which the latter accept of a part of the debt in compensation for the whole.

Composition, in printing, commonly termed composing, is the arranging of the types, or letters, in the composing-stick, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several pages to make a form.

Composition of motion, is an assemblage of several directions of motion, resulting from several powers acting in different, though not opposite directions.

Composition of proportion, is the comparing the sum of the antecedent and consequent, with the consequent in two equal ratios; as suppose, 4 : 8 : : 3 : 6, they say, by composition of proportion, 12 : 8 : : 9 : 6. The same holds of the sum of the antecedent and consequent, compared with the antecedent: thus we say 12 : 4 : : 9 : 6. There is a great difference between composition of proportion by addition and by multiplication. See Proportion.

COMPOST, in husbandry and gardening, several sorts of soils, or earthy matters mixed together, in order to make a manure, for assisting the natural earth in vegetation.

COMPOSTO, in music, means compounded or doubled, as a fifteenth is an octave doubled, or an octave is compounded of a fifth and a fourth.

COMPOUND ***flower***, one consisting of several distinct lesser flowers, or corollulæ, each furnished with a style, stamina, &c. The corollulæ are of two kinds, viz. tubulated and ligulated: the tubulated are always furnished with a campanulated limb, divided into four or five segments; whereas the ligulated corollulæ have only a flat, linear limb, terminated by a single point, or by a broader extremity, divided into three or five segments. The plants with compound flowers are extremely numerous, forming a class by themselves, called by Linnæus syngenesia.

COMPRESSION, the act of pressing matter, so as to set its parts nearer to each other, and make it possess less place.

Water was, during a very long period, considered as a fluid perfectly unelastic; that is, unyielding, or incompressible; and this opinion was corroborated by an experiment of the Academy del Cimento in Italy. This opinion prevailed until the year 1761, when Mr. Canton discovered the compressibility of water, and of other liquids, which he immediately made known to the Royal Society. He took a glass tube, having a ball at one end, filled the ball and part of the tube with water, which he had deprived of air as much as it was in his power; then placed the glass thus filled under the receiver of an air-pump; and on exhausting the receiver, which removed the pressure of the atmosphere from the water and the glass vessel which contained it, in consequence of which the water rose a little way into the tube, viz. expanded itself. He then placed the apparatus under the receiver of a condensing engine, and on forcing the air into it, which increased the pressure upon the water, a diminution of bulk evidently took place; the water descending a little way within the tube.

COMPTONIA, a genus of the monœcia triandria class and order. The male cal. is an ament, two-leaved; cor. none; anthers two-parted. The female is also an ament, cal. six-leaved; cor. none; styles two; nect. ovate. There is one species, a shrub of North America.

CONCENTRATION, in chemistry, the act of increasing the strength of fluids, which are rendered stronger by abstracting a portion of the mere menstruum. This is generally effected by evaporation, where the menstruum is driven off at a lower heat than is required to drive off the substance with which it is united. Thus, dilute sulphuric acid may be considered as a mixture of the real acid with water; and by applying a certain heat the water may be evaporized, leaving the acid behind in a state of concentration

CONCENTRIC, in mathematics, something that has the same common centre with another: it stands in opposition to eccentric.

CONCERT, a musical performance in which any number of practical musicians, either vocal or instrumental, or both, unite in the exercise of their respective talents. The concerts of the ancient Greeks were executed only in the unison or octave.

CONCERTO, a composition expressly written for the display of some particular instrument, with accompaniments for the band.

CONCERTATO intimates the piece of music is composed in such a manner, as that all the parts may have their recitativos.

CONCESSION, in rhetoric, a figure, whereby something is freely allowed, that yet might bear dispute, to obtain something that one would have granted.

CONCHA, in anatomy, the larger cavity of the external ear, situated before the meatus auditorius or passage into the internal ear.

CONCHOID, in geometry, the name of a curve, given by its inventor Nicomedes.

This curve was used by Archimedes and other ancients, in the construction of solid problems; and Sir Isaac Newton says that he himself prefers it before other curves, or even the conic sections, in the construction of cubic and biquadratic equations.

CONCORD, in grammar, that part of con

struction, or syntax, in which the words of a sentence agree; that is, in which nouns are put in the same gender, number, and case; and verbs in the same number and person with nouns and pronouns.

Concord, in music, the relation of two sounds that are always agreeable to the ear, whether applied in succession or consonance. See Music.

CONCORDANCE, a sort of dictionary of the Bible, explaining the words thereof in alphabetical order, with the several books, chapters, and verses quoted, in which they are contained.

The best work of this kind which we have in the English language is that of Alexr. Cruden.

CONCRETE, in logic, is used in contradistinction to abstract; for example, when we consider any quality, as whiteness, inhering in any subject, as suppose in snow, if we may say the snow is white, then we speak of whiteness in the concrete; but if we consider whiteness by itself, as a quality that may be in paper, in ivory, and in other things, as well as in snow, we are then said to consider, or to take it in the abstract.

CONCRETIONS, *morbid*, in animal economy, hard substances that occasionally make their appearance in different parts of the body, as well in the solids as in those cavities destined to contain fluids.

CONDENSER, a pneumatic engine or syringe, whereby an uncommon quantity of air may be crowded into a given space; so that sometimes ten atmospheres, or ten times as much air as there is at the same time in the same space, without the engine, may be thrown in by means of it, and its egress prevented by valves properly disposed. See Pneumatics.

CONDITION, in the civil law, a clause of obligation stipulated as an article of a treaty or contract; or in a donation of testament, legacy, &c; in which last case a donee does not lose his donative, if it is charged with any dishonest or impossible conditions.

Condition, in common law, a restraint annexed to a thing, so that by the non-performance the party to it shall sustain loss, and by the performance receive advantage.

CONDITIONAL *syllogism*, a syllogism where the major is a conditional proposition. Thus,

If there is a God, he ought to be worshipped.
But there is a God;
Therefore he ought to be worshipped.

CONDUCTOR, in surgery, an instrument which serves to conduct the knife in the operation of cutting for the stone, and in laying up sinuses and fistulas.

Conductor, in electricity. All bodies are divided into conductors and non-conductors. The latter are called electrics. See Electricity.

CONE, in geometry, a solid figure, having a circle for its base, and its top terminated in a point or vertex. See Conic Sections.

CONFERVA, a genus belonging to the cryptogamia class of plants, and in the natural method ranking under the 57th order, algæ. There are 21 species, most of which grow on stones in slow streams, on the sides of cisterns, or in ponds.

CONGELATION, may be defined the transition of a liquid into a solid state, in consequence of an abstraction of heat: thus metals, oil, water, &c. are said to congeal when they pass from a fluid into a solid state. With regard to fluids, congelation and freezing meaning the same thing. Water congeals at 32°, and there are few liquids that will not congeal, if the temperature be brought sufficiently low. The only difficulty is to obtain a temperature equal to the effect; hence it has been inferred that fluidity is the consequence of caloric. Every particular kind of substance requires a different degree of temperature for its congelation, which affords an obvious reason why particular substances remain always fluid, while others remain always solid, in the common temperature of the atmosphere, and why others are sometimes fluid, and at others solid, according to the vicissitudes of the seasons, and the variety of climates.

Under the article Freezing, will be given a short table of freezing mixtures, the remaining part of this article shall be devoted to the new and elegant mode of congelation by the air-pump, originally, we believe, invented by Mr. Nairn, but brought to its present state of perfection by Professor Leslie of Edinburgh.

Accounts of this most beautiful experiment have been published in different philosophical works, but many of them are stated in such a form as is rather calculated to mar the efforts of the experimentalist, than to insure his success.

The following directions are offered as the result of a repetition of the process more than a hundred times, under almost every variety of form in which it could be effected.

Place on the plate of the air-pump a flat circular vessel of glass, of such a diameter as the size of the plate will admit, and of about an inch in depth. Pour into this vessel as much of the best sulphuric acid that can be obtained as will fill it to rather better than the depth of half an inch, place in the centre of the dish, containing the acid, a small metallic ring supported by three glass legs; and in this ring place a cup of *porous earthen ware*, containing the water to be frozen. Cover the whole with a low receiver, and push the exhaustion as far as the nature of the circumstances will admit.

During the process of exhaustion there will be perceived, in the water, the appearance of a delicate effervescence; in about five or six minutes after it is completed, there will appear a slight degree of roughness about the edge of the water; and in from five, to ten minutes more, the congelation will be seen to sweep over the whole surface of the water, obscuring it like a cloud. The congelation will now proceed rapidly; and in the space of an hour the mass will become solid, and may be removed from the cup. It may be necessary here to observe that the above statement has reference to the process as conducted on the common air-pump: when the large and powerful apparatus used by Mr. Leslie is employed, the effect will be produced in a shorter time, and on a greater quantity of water. From the Professor's own account of this experiment it would appear that, instead of a porous earthen ware cup, he sometimes used a glass one. He has not stated what the effect of this difference was; perhaps with his superior pump it might

be inconsiderable, but the case is far otherwise when the experiment is made on a small scale, as the following facts incontestibly prove. About a *table spoonful* of water was exposed in a glass cup to the action of a surface of acid of eight inches in diameter, and three quarters of an inch in depth; the receiver was exhausted, and the whole suffered to remain in this state for an hour, and in some instances, for two hours, but not the smallest symptom of freezing appeared, although a considerable evaporation took place. It was then removed, and four times the quantity of water, of the same temperature, put in a *porous cup*, was placed under the receiver, and over the same acid; before the exhaustion was completed, numerous star-like particles appeared on the surface of the water; and in exactly four minutes and a half, after it was completed, feathered spiculæ of ice shot across in every direction. At this instant the cup was removed, and although there appeared no ice at the bottom, yet on pouring out the water, a beautiful sheet of ice, perfectly transparent, and resembling a watch glass, was found adhering firmly to the cup, but which was easily separated by the application of a slight degree of warmth.

Instead of using sulphuric acid as an absorbent in this process, parched oatmeal, dry porphyritic trap, and pipe-clay have been recommended, but neither of these is so effectual as the acid, as any one will soon find who chooses to make the trial. Fig 5. Plate X. exhibits a section of the requisite apparatus for performing artificial congelation. AA, is the plate of the air-pump; B the glass bason containing the sulphuric acid; C the cup of porous earthen ware, containing the water to be frozen, and placed in its stand; and D the hemispherical glass receiver.

CONIC *sections* are curve lines formed by the mutual intersection of a plane, and the surface of a solid. The nature and properties of these figures formed a most extensive branch of the ancient geometry, and in modern times the greater part of the discoveries of the last century must appear absolutely unintellegible without a tolerable knowledge of conic geometry. These sections are derived from the different directions in which the solid cone is cut, by a plane passing through it; and they are, a triangle, a circle, an ellipse, a parabola, and an hyperbola. The mode of obtaining these sections is as follows.

If a cone be cut by a plane through the vertex, the section will be a triangle, ABC fig. 1. If the cone be cut by a plane parallel to the base, the section will be a circle. If by a plane DEF in such a direction that the side AC of a triangle passing through the vertex and its base perpendicular to EF may be parallel to DP the section is a parabola; if by a plane (DR fig. 2) meeting AC, the section is an ellipse; if by a plane DMO, fig. 3, meeting AC extended beyond A, it is an hyperbola.

If a line HG, fig. 1. be drawn in a parabola perpendicular to DP the square of HG will be to that of FP as DG to DP; for let LHK be a section parallel to the base, and consequently a circle, the rectangle LGK will be equal to the square of HG, and the rectangle BPC=the square of EP; ∴ these squares will be to each other as their rectangles.

There are three ways of investigating the properties of these curves. 1. By taking the demonstrations from the sections of a cone. 2. By taking a general property of the figures on a plane from which the others may be determined geometrically, or by taking the general property of each curve, and from it deducing all the other properties of the same curve. 3. By taking the equation to all the curves from whence their respective properties may be had by algebra, or by taking the equation to each singly, from whence its properties may be found by the same means.

Hereby the general property of conic sections is discovered, which makes the basis of the other methods. If they are considered as curves on a plane, they have the same properties as those formed by the intersections of a plane with a cone: and again the equation is produced which forms the basis of an algebraical process. Boscovich has deduced the properties of the three curves from one common property, and his method has been simplified by Mr. Newton of Cambridge. The foundation of his method is the mutual relation of two lines, one drawn from a given point, the other perpendicular to a line in a given position. I. If a point S be assumed without the line DX, fig. 4, and 5. and while the line SP revolves about S as a centre, a point P moves in it, so that its distance from S shall always be to PE, its distance from the line DX in a given ratio; the curve described by the point P is called a conic section, a parabola, an ellipse, or a hyperbola, as SP is equal to, less or greater than PE. II. The indefinite right line DX, is named the directrix. III. The point S is the focus. IV. The ratio of SP to PE is the determining ratio. V. If a line SD be drawn through the focus perpendicular to the directris, it is called the axis of the conic section. VI. The point A is the vertex. VII. A right line LST drawn through the focus parallel to the directrix and terminated by the curve in the points L, T is the principal parameter, or the latus rectum. *Corollaries.* (1.) SP being greater than PE, in the hyperbola, two curves will be described, which are called opposite hyperbolas. (2.) When the line SP comes into the position SAD; SP, PE, will be equal to SA, AD; ∴SA is to AD in the determining ratio. (3.) When SP comes into the position SL or ST, the distance of P from the directrix will be equal to SP and SL, or ST will be to SD in the determining ratio; ∴ the latus rectum LT is bisected in S. (4.) The latus rectum in the parabola is equal to double the distance of the locus from the directrix or to four times that from the vertex · for SL=SD, and SA=AD, ∴ LT=twice SD, or four times SA. VIII. The tangents DLQ, DTQ, fig. 6. and 7, which are drawn through the extremities of the latus rectum are called focal tangents. IX. The line AM in the ellipse and hyperbola, is termed the transverse axis, or major axis. X. If the transverse axis is bisected in C, the point C is called the centre of the ellipse or hyperbola. XI. If a line BC*b* bisected in C, be drawn perpendicularly to the transverse axis, and CB, C*b* be each a mean proportional between SA, SM, the segments of the axis intercepted between the focus and the vertices BC*b* is called the conjugate axis, or axis minor. XII. A right line PN*p* drawn through any point N in the axis parallel to the

tangent KAG, or perpendicular to the axis, and terminated by the curve in the points P and p is called an ordinate to the axis. XIII. And the segment of this axis AN intercepted between the ordinate and vertex in all the sections, also the other segment NM in the ellipse and hyperbola, is termed an abscissa. XIV. A line passing through the centre of an ellipse or hyperbola, which is terminated both ways by the curve in the former, and by the opposite curves in the latter, is called a diameter. XV. A line drawn through a point in the parabola parallel to the axis is a diameter to the parabola. XVI. The point where a diameter meets the curve, is a vertex to that diameter. XVII. If from the centre C, at the distance CA, (fig. 8.) half the transverse axis, a circle be described, cutting the directrix of the hyperbola in the points Hh, and lines be drawn from the centre through the points of intersection, they are called asymptotes. XVIII. If AM be the transverse axis, and Bb the conjugate axis of two opposite hyperbolas, and two other hyperbolas be described, the transverse axis, of which is Bb, and the conjugate AM, these last hyperbolas are conjugate to the former. XIX. If the two axes are equal, the hyperbolas are equilateral. XX. A right line drawn through any point in the diameter of a conic section, parallel to the tangent at its vertex, terminated both ways by the curve, is called an ordinate to that diameter. XXI. A diameter parallel to the tangent at the vertex of any diameter of the ellipse or hyperbola, is termed a conjugate diameter. XXII. A line which is a third proportional to any diameter of the ellipse or hyperbola and its conjugates is called a parameter to that diameter. XXIII. A line drawn through the focus of a parabola parallel to the ordinates of any diameter which is terminated both ways by the curve, is called a parameter to the diameter.

From these fundamental properties all the others are derived, and the curves may be mechanically described. This description depends, for the *parabola*, on the property that a line from a point in the curve to the focus, is equal to one drawn from the same point perpendicularly on the directrix; for the *ellipse*, on the property that the sum of the lines from the foci to a point is equal to the major axis; for the *hyperbola*, that the difference of the lines from the foci to a point in the curve is equal to the major axis.

Description of Conic sections on a plane.

1. *Parabola.* Let AB, (fig. 9.) be a right line and C a point without it, and DKF a ruler in the same plane, with the line and point so that one side as DK, be applied to AB, and KF, coincide with the point C and at F, fix one end of the thread at FNC, and the other at the point C; and let part of the thread, as FN, be brought to the side KF by a pin N; then let the square DKF, be removed from B to A, applying its side DK close to BA; and in the mean time the thread will be always applied to the side KF; and by the motion of the pin N will be described a curve called a semi-parabola. Then, bringing the square to its first position, moving from B to H the other semi-parabola will be described.

2. *Ellipse.* If two points as A and B, (fig. 10.) be taken in any plane, and in them is fixed a thread longer than the distance between them, and this extended by means of a pin C; and the pin be moved round from any point till it return back again to the same place, the thread being extended all the while, the figure described is an ellipse.

3. *Hyperbola.* If to the point A (fig. 11.) one end of the ruler AB be placed so that about that point as a centre it may freely move; and if to the other end B is fixed the extremity of the thread BDC, shorter than the ruler AB, and the other end of the thread fixed in the point C, coinciding with the side of the ruler AB in the same place with the given point A; let part of the thread BD be brought to the side of the ruler AB by the pin D; then let the ruler be moved about the point A, from C to T, the thread extended, and the remaining part coinciding with the side of the ruler; by the motion of the pin D a semi-hyperbola will be described. The ellipse returns into itself. but the parabola and hyperbola are unlimited.

If a line GM (fig. 9.) be drawn from a point in a parabola perpendicular to the axis, it will be an ordinate to the axis, and its square will be equal to the rectangle under the abcissa MI and latus rectum; for because GMC is a right angle, GM^2 is equal to the difference of GC^2 and CM^2; but GC is equal to GE, which is equal to MB; therefore GM^2 is equal to $BM^2—CM^2$; which, because CI and IB are equal, is (8 Euc. 2.) equal to four times the rectangle MI and IB, or equal to the rectangle under MI and the latus rectum.

From the genesis of the sections may be seen how one section degenerates into another. For an ellipsis being that plane of any section of the cone between the circle and parabola, it is easy to perceive that there may be a great variety of ellipses produced from the same cone; and when the section is parallel to one side of the cone, then the ellipsis becomes a parabola. This again being that section whose plane is always parallel to the side of the cone cannot vary as the ellipsis may; for when it moves from its parallel position, it degenerates into an ellipsis or hyperbola, therefore a circle may change into an ellipsis, the ellipsis into a parabola, the parabola into an hyperbola, and this again into an isosceles triangle.

Of Equations of Conic Sections.

The equation of a curve is an algebraic expression, denoting the relation between the ordinate and abscissa: the latter equal to x, and the former to y.

Let p be the parameter of a parabola, then $y^2=px$; the equation for all parabolas. Let a be the diameter of an ellipse and p, the parameter; then $y^2=\frac{p}{a}—\overline{ax+x^2}$ the equation for all ellipses.

Let a be the transverse diameter of an hyperbola, and p its parameter; then $y^2=\frac{a}{p}\times\overline{ax+x^2}$. If a be the second diameter then $y^2=\frac{p}{n}\times\overline{a^2+x^2}$, these are the equations for hyperbolas. As all equations are expressed by the second powers of x and y, all conic sections are curves of the second order: and again the locus of every quadratic equation is a conic section, therefore is a parabola, an ellipse, or hyperbola, as the form of the equation agrees with the above, or with any other, de-

duced from lines drawn in a different way with regard to the section.

Properties peculiar to the hyperbola.—As the hyperbola has some curious properties arising from its asymptotes which appear at first view almost incredible, we shall briefly demonstrate them.

(1) The hyperbola and its asymptotes never meet: if not, let them meet in S (fig. 11;) then by the property of the curve the rectangle $KX \times XE$ is to SX^2 as GE^2 to GM^2 or EP^2; that is, as GX^2 to SX^2; wherefore $KX \times XE$ will be equal to the square of GX; but the rectangle $KX \times XE$, together with the square of GE, is also equal to the square of GX; which is absurd.

(2) If a line be drawn through an hyperbola parallel to its second axis, the rectangle, by the segments of that line, betwixt the point in the hyperbola and the asymptotes, will be equal to the square of the second axis.

For if SZ (fig. 11.) be drawn perpendicular to the second axis, by the property of the curve, the square of MG, that is, the square of PE, is to the square of GE, as the squares ZG and the square of MG together, to the square of SZ or GX; and the squares of RX and GX are in the same proportion, because the triangles RXG, PEG; are equiangular; therefore the squares ZG and MG are equal to the square of RX; from which, taking the equal squares of SX and ZG, there remains the rectangle RSV, equal to the square of MG.

(3) Hence, if right lines be drawn parallel to the second axis, cutting an hyperbola and its asymptotes, the rectangles contained betwixt the hyperbola and points where the lines cut the asymptotes will be equal to each other; for they are severally equal to the square of the second axis.

(4) If from any points, d and S, in an hyperbola, there be drawn lines parallel to the asymptotes $d\,a$ SQ and S $b\,d\,c$, the rectangle under $d\,a$ and $d\,c$ will be equal to the rectangle under QS and S b; also the parallelograms $d\,a$ G c, and SQG b, which are equiangular, and consequently proportional to the rectangles, are equal.

For draw YW RV parallel to the second axis, the rectangle $Y\,d \times d\,W$ is equal to the rectangle $RS \times SW$; wherefore WD is to SV as RS is to d Y. But because the triangles RQS, a YD, and GSV, $c\,d$ W, are equiangular, W d is to SV as $c\,d$ to S b, and RS is to DY as SQ to $d\,a$; wherefore, $d c$ is to S b as SQ to $d\,a$; and the rectangle $d\,c$, $d\,a$, is equal to the rectangle QS, S b.

(5) The asymptotes always approach nearer the hyperbola.

For, because the rectangle under SQ and S b or QG, is equal to the rectangle under $d\,a$ and $d\,c$, or AC and QG is greater than a G; therefore, $d\,a$ is greater than QS.

(6) The asymptotes come nearer the hyperbola than any assignable distance.

Let X be any small line. Take any point, as d, in the hyperbola, and draw $d\,a$, $d\,c$ parallel to the asymptotes: and as X is to $d\,a$, so let a G be to GQ. Draw QS parallel to $a\,d$, meeting the hyperbola in S; then QS will be equal to X. For the rectangle $SQ \times QG$ will be equal to the rectangle $d\,a \times a\,G$; and consequently SQ is to $d\,a$ as AG to GQ.

If any point be taken in the asymptote below Q, it can easily be shown that its distance is less than the line X.

General properties of conic sections.—A tangent to a parabola bisects the angle contained by the lines drawn to the focus, and directrix; in an ellipse and hyperbola, it bisects the angle contained by the lines drawn to the foci. In all sections, lines parallel to the tangent are ordinates to the diameter passing through the point of contact, and in the ellipse and hyperbola, the diameters parallel to the tagent, and those passing the points of contact, are conjugate to each other. If an ordinate be drawn from a point to a diameter, and a tangent from the same point which meets the diameter produced in the parabola, the part of the diameter between the ordinate and tangent will be bisected in the vertex; and in the ellipse and hyperbola, the semi-diameter will be a mean proportional between the segments of the diameter, the centre and ordinate, and the centre and tangent. The parallelograms, formed by tangents drawn through the vertices of any conjugate diameter, in the same ellipses or hyperbola, will be equal to each other.

CONJUGATE *diameter*, or axis of an ellipsis, the shortest of the two diameters, or that bisecting the transverse axis.

CONJUGATE *hyperbolas.* See CONIC SECTIONS.

CONJUGATION, in grammar, a regular distribution of the several inflections of verbs in their different voices, moods, tenses, numbers, and persons, so as to distinguish them from one another.

The English have scarcely any natural inflexions, deriving all their variations from additional particles, pronouns, &c. whence there is scarcely any such thing as strict conjugation in that language.

CONIUM, *hemlock*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. There are five species; the most remarkable are,

1. Conium Africanum, with prickly seeds, a native of the Cape of Good Hope, and rarely growing above nine inches high: the leaves are of a greyish colour, and the flowers are white.

2. Conium maculatum, or the greater hemlock, grows naturally on the sides of banks and roads in many parts of Britain. It is a biennial plant, which perishes after it has ripened its seeds. The stalk is smooth, spotted with purple; and rises from four to upwards of six feet high, branching out towards the top, with decompounded leaves. The stalks are terminated by umbels of white flowers. This species is poisonous when taken in large quantities, yet it is found very efficacious in some diseases.

3. Conium tenuifolium, with striated seeds. This is also a biennial plant, and much resembles the preceding. It is a native of Germany.

CONJUNCTION. See ASTRONOMY.

CONNARUS, *Ceylon Sumach*, a genus of the decandria order, in the monadelphia class of plants, ranking under the dubious in the natural method. Of the four species, the most remarkable is the connarus monocarpus, a native of India, which grows to the height of eight or ten feet, and the stalk is covered with a thick black bark.

CONOID, in geometry, a solid body, generated by the revolution of a conic section about its axis.

CONOPS, a genus of insects of the order of diptera, of which there are 13 species. 1. The Calcitrans, is to be found every where, especially in autumn, when it is a great torment to horses. 2. The macrocephala, resembles a wasp, but is variegated with yellow, black, red, and brown. The other species are not remarkable.

CONSANGUINITY, or kindred, is the connection or relation of persons descended from the same stock or common ancestor; and is either lineal or collateral. Lineal consanguinity is that which subsists between persons, of whom one is descended in a direct line from the other; as grandfather, father, and son. Collateral consanguinity is that which subsists between persons descended from the same common ancestor, but not from one another; as brothers, uncles, and nephews.

Consanguinity terminates in the sixth and seventh degree, excepting in the succession of the crown, in which case it is continued to infinity.

CONSCIENCE, in ethics, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil.

CONSEQUENT *of a ratio*, in mathematics, the latter of the two terms of a ratio, or that to which the antecedent is compared; thus in $m : n$, or m to n, n is the consequent, and m the antecedent.

CONSIGNMENT, the sending, or delivering over, goods, money, or other property, to another person. It may be either consigned unconditionally, or for some particular purpose. Consigned goods are supposed in general to be the property of him *by* whom they are consigned, but to be at the disposal of him *to* whom they are consigned.

CONSONANCE, in music, is the effect of two or more sounds heard at the same time; but its general signification is confined to concording intervals.

CONSONANT, a letter that cannot be sounded without some single or double vowel before or after it. Consonants are first divided into single and double; the double are *x* and *z*, the rest are all single: and these are again divided into mutes and liquids; eleven mutes, *b, c, d, f, r, g, j, k, p, q, t*; and four liquids, *l, m, n, r*. But the most natural division of consonants is that of the Hebrew grammarians, who have been imitated by the grammarians of other oriental languages.

CONSPIRACY, in law, signifies an agreement between two or more, falsely to indict, or procure to be indicted, an innocent person for felony.

CONSTELLATION, in astronomy, a system of several stars that are seen in the heavens near to one another. See ASTRONOMY.

CONSTITUTION, in matters of policy, signifies the form of government established in any country or kingdom.

The constitution and government of a country frequently differ, though the latter should be founded on the former in every particular.

CONSTITUTION also denotes an ordinance, decision, regulation, or law, made by authority of any superior, ecclesiastical or civil. The constitutions of the Roman emperors make a part of the civil law, and the constitutions of the church make a part of the canon law.

CONSTRUCTION, in geometry, is the drawing such lines, such a figure, &c. as are previously necessary for the making any demonstration appear more plain and undeniable.

CONSTRUCTION *of equations*, in algebra, the method of drawing a geometrical figure whose properties shall express the given equation, in order to demonstrate the truth of it geometrically.

CONSUL, is an officer established by virtue of a commission from the King, and other princes, in all foreign countries of any considerable trade, to facilitate and despatch business, and protect the merchants of the nation.

CONSUMPTION, in medicine, a word of very extensive signification, implies all disorders that bring any decay or waste upon the constitution.

CONTACT, is when one line, plane, or body, is made to touch another, and the parts that do thus touch are called the points or places of contact.

CONTENT, in geometry, the area or quantity of matter or space included in certain bounds.

CONTIGUOUS *angles*, in geometry, are such as have one leg common to each angle; and are sometimes called adjoining angles, in contradistinction to those produced by continuing their legs through the point of contact, which are called opposite or vertical angles.

CONTINENT, in geography, a great extent of land not interrupted by seas, in contradistinction to island, peninsula, &c.

CONTINGENT, something casual or uncertain. Hence future contingent, in logic, denotes a conditional event which may or may not happen, according as circumstances fall out.

CONTINGENT is also a term of relation for the quota that falls to any person upon a division. Thus each prince in Germany, in time of war, was formerly obliged to furnish so many men, so much money and ammunition for his contingent.

CONTINGENT *use*, in law, is a use limited in a conveyance of lands which may or may not happen to vest, according to the contingency mentioned in the limitation of the use.

CONTINUED *proportion*, in arithmetic, is that where the consequent of the first ratio is the same with the antecedent of the second; as $4 : 8 :: 8 : 16$, in contradistinction to discrete proportion.

CONTOUR, the outline of a figure. It is sometimes used with great latitude, to express the general cast or lineaments of the visage See PAINTING.

CONTRABAND, in commerce, a prohibited commodity or merchandize bought or sold, imported or exported, in prejudice to the laws and ordinances of a state, or the public prohibitions of the sovereign.

CONTRACT, a covenant or agreement between two or more persons, with a lawful consideration or cause. Contracts are either express or implied. Express contracts are, where the terms of the agreement are openly

uttered, as to pay a stated price for certain goods. Implied, are such as reason and justice dictate, and which therefore the law presumes that every man undertakes to perform.

CONTRA-*harmonical proportion*, in arithmetic, is that relation of three terms, wherein the difference of the first and second is to the difference of the second and third as the third is to the first: thus, 3, 5, and 6, are numbers contra-harmonically proportional, for 2 : 1 : : 6 : 3.

CONTRAST, the artificial opposition in works of painting and sculpture, of groups, attitudes, or colours; so as by their variety and striking difference, to strengthen the effect of the whole.

CONTRATE-*wheel*, in watch-work, that next to the crown, the teeth and hoop of which lie contrary to those of the other wheels, whence it takes its name.

CONTRAVALLATION, in the military art, implies a line formed in the same manner as the line of circumvallation, to defend the besiegers against the enterprises of the garrison; so that the army forming a siege lies between the lines of circumvallation and contravallation.

CONTRAYERVA, in the materia medica, the name by which the root of the dorstenia plant is known in the shops.

CONTRE, in heraldry, an appellation given to several bearings, on account of their cutting the shield contrary and opposite ways.

CONTROLLER, an officer appointed to control or oversee the accounts of other officers, and, on occasion, to certify whether or no things have been controlled or examined. In England we have several officers of this name, controller of the King's house, controller of the navy, controller of the customs, controller of the mint, &c.

CONTUMACY, in law, a refusal to appear in court, when legally summoned; or the disobedience to the rules and orders of a court, having power to punish such offence.

CONVALLARIA, or *lily of the valley*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under sarmentaceæ, or 11th order. The species are 11, two of which are natives of Britain, viz. the maialis, or May lily; and the multiflora, or Solomon's seal. They are plants of considerable beauty, and may be propagated by their creeping roots.

CONVENTION, a treaty, contract, or agreement between two or more parties. Every convention among men, provided it be not contrary to honesty and good manners, produces a natural obligation, and makes the performance a point of conscience.

CONVENTICLE, a diminutive of *convent*; denoting properly a cabal, or secret assembly, of a part of the monks of a convent, to make a brigue or party in the election of an abbot. From the ill use of these assemblies the word is come into disrepute; and now stands for any mischievous, seditious, or irregular assembly. The term conventicle is said, by some, to have been first applied in England to the schools of Wickliffe; and has been since used to signify the religious assemblies of all in this country who do not conform to the established doctrines and worship of the church of England.

CONVERGING or *convergent lines*, in geometry, are such as continually approach nearer one another, or whose distance becomes still less and less.

CONVERGING *hyperbola*, is one whose concave legs bend in towards one another, and run both the same way.

CONVERGING *rays*, in optics, those rays that, issuing from divers points of an object, incline towards another, till they meet and cross, they then become diverging rays. See OPTICS.

CONVERSE, in mathematics. One proposition is called the converse of another, when, after a conclusion is drawn from something supposed in the converse proposition, that conclusion is supposed; and then, that which in the other was supposed, is now drawn as a conclusion from it.

CONVERSION *of equations*, in algebra, is when the quantity sought, or any part or degree of it, being in fractions, the whole is reduced to one common denomination, and then omitting the denominators, the equation is continued in the numerators only.

CONVERSION *of propositions*, in logic, the changing of the subject into the place of the predicate, and the predicate into the place of the subject; and yet always retaining the same quality of both propositions.

CONVEX, an appellation given to the exterior surface of gibbous or globular bodies, in opposition to the hollow inner surface of such bodies, which is called concave.

CONVEYANCE, in law, a deed which passes land from one to another. The most common conveyances now in use are, deeds of gift, bargain and sale, lease and release, fines and recoveries, settlements to uses, &c.

CONVOLVULUS, in botany, a genus of the pentandria monogynia class and order. Natural order of campanaceæ, or bell-form flowers. Essential character: corolla bell-shaped, plaited; stigmas two; capsules two-celled, with two seeds in each cell. There are 110 species of this very numerous genus, not more than thirteen species are natives of Europe; the others are mostly inhabitants of the warmer climates of Asia and America. Very few of them are cultivated in our gardens, except C. purpureus, purple bindweed; and C. tricolor, trailing bindweed, more commonly known by the names of convolvulus, major and minor; the stems are herbaceous and milky, in the greater part twining, in a very few shrubby; leaves alternate; peduncles axillary or terminating, one flowered, with two bractes, or many flowered

CONVOY, in marine affairs, one or more ships of war, employed to accompany and protect merchants' ships, and prevent their being insulted by pirates or the enemies of the state in time of war.

CONVOY, in military affairs, a detachment of troops employed to guard any supply of men, money, ammunition, provisions, stores, &c. conveyed in time of war, by land or sea, to a town or army.

CONVULSION, *spasmus*. See MEDICINE.

CONYZA, *fleabane*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are 41 species, none of which merit any particular description.

COOPER, one who manufactures casks, tubs of all sizes, pails, and some other similar articles used in domestic concerns. These are made generally of oak timber; a great part of which comes from America, cut up into narrow pieces or staves; they are sometimes bent, and sometimes straight, according to the purposes for which they are wanted. The staves are kept together by means of hoops, made from hazel or ash, or of iron.

COPAIFERA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under those of which the order is doubtful. There is but one species, the officinalis, which yields the copaiba balsam. This tree grows in the province of Antiochi, in the Spanish West Indies. Some of these trees do not yield any balsam; those which do are distinguished by a ridge which runs along their trunks. These trees are wounded in the centre; and one of them will yield five or six gallons of balsam.

COPAL, improperly called *gum copal*, is a hard, shining, transparent, citron-coloured, odoriferous, concrete juice of an American tree, but which has neither the solubility in water common to gums, nor the solubility in alcohol common to resins, at least in any considerable degree. By these properties it resembles amber. It may be dissolved by digestion in linseed oil, rendered drying by quick-lime, with a heat very little less than sufficient to boil or decompose the oil. This solution, diluted with oil of turpentine, forms a beautiful transparent varnish, which, when properly applied, and slowly dried, is very hard, and very durable. This varnish is applied to snuff-boxes, tea-boards, and other utensils. It preserves and gives lustre to paintings, and greatly restores the decayed colours of old pictures, by filling up the cracks, and rendering the surfaces capable of reflecting light more uniformly.

COPPER, a metal next to iron in specific gravity, but lighter than gold, silver, or lead.

This metal is of a fine red colour, and has a great deal of brilliancy. Its taste is styptic and nauseous; and the hands when rubbed for some time on it, acquire a peculiar and disagreeable odour. Its malleability is great it may be hammered out into leaves so thin as to be blown about by the slightest breeze. Its ductility is also considerable. Its tenacity is such, that a copper wire 0.078 inch in diameter is capable of supporting 302.26 pounds avoirdupoise without breaking. See CHEMISTRY.

COPPERAS is the sulphate of iron, and is commonly called green vitriol. If sulphuric acid be diluted with water, and be poured upon iron, much effervescence will be seen: the metal will be dissolved, and the solution, when evaporated, will exhibit the sulphate of iron, or common copperas, which is a neutral salt in a very impure state.

COPULA, in logic, the verb that connects any two terms in an affirmative or negative: as, "Riches make a man happy;" where *make* is the copula.

COPULATIVE *propositions*, in logic, those where the subject and predicate are so linked together by copulative conjunctions, that they may be all severally affirmed or denied one of another

COPY, in a legal sense, is the transcript of an original writing: as the copy of a patent, of a charter, deed, &c.

COPY, among printers, denotes the manuscript, or original of a book, given to be printed.

COPYHOLD, in the law of England, is a species of land tenure, evidently the offspring of the ancient tenure in villenage. It is called *copy-hold* because the tenant holds his lands by copy of court roll of the manor at the will of the lord.

COPYING *machine*. See POLYGRAPH.

COPY-*right*. See LITERARY PROPERTY.

COR *Caroli*, in astronomy, an extra-constellated star in the northern [illegible]misphere, situated between the Coma Berenices, and Ursa Major, so called by Dr. Halley in honour of King Charles,

COR *Hydræ*, a fixed star of the first magnitude, in the constellation of Hydra.

COR *Leonis*, or *Regulus*, in astronomy, a fixed star of the first magnitude, in the constellation Leo.

CORACIAS, the roller, a genus of birds of the order of picæ. Sixteen species have been enumerated, though some of them are suspected to be only varieties. The following are the most remarkable:

1. The garrula, or garrulous roller, is about the size of a jay: the bill black, and at the base beset with bristles; the head, neck, breast, and belly, are of a light-bluish green; back and scapulars, reddish brown; coverts on the ridge of the wing, a rich blue, beneath a pale green; upper part and tips of the quills dusky; the lower parts of a fine deep blue, tail forked, of a light blue; the legs are short and of a dirty yellow. Mr. Pennant observes that these birds are frequent in several parts of Europe. The flesh tastes like that of a turtle.

2. The cyanea, or blue-striped roller is eight inches long; the bill three quarters of an inch long, bent at the tip, and of a black colour; the general colour of the plumage deep blue-black, dashed with streaks of greenish blue; the tail and legs are black; it inhabits New Caledonia.

3. The sinensis, or Chinese roller is of the size of a jay, the bill and irides are red, but the general plumage is green. It is a native of China, but not very common.

CORAL *fishery*. Red coral is found in the Mediterranean, on the shores of Provence, from Cape de la Couronne to that of St. Tropez; about the isles of Majorca and Minorca; on the south of Sicily; on the coast of Africa; and, lastly, in the Ethiopic ocean, about Cape Negro. The divers say, that the little branches are found only in the caverns whose situation is parallel to the earth's surface and open to the south. The manner of fishing being nearly the same wherever coral is found, it will suffice to instance the method used at the bastion of France, under the direction of the company established at Marseilles for that fishery Seven or eight men go in a boat commanded by the patron or proprietor, and when the net is thrown by the caster, the rest work the vessel, and help to draw the net in. The net is composed of two rafters of wood tied crosswise, with leads fixed to them: to these they fasten a quantity of hemp twisted loosely round, and intermingled with some large net-

ting. This instrument is let down where they think there is coral, and pulled up again when the coral is strongly entangled in the hemp and netting.

CORALLINA, or *coral*, a genus belonging to the order of vermes zoophyta. The species are distinguished by the form of their branches, and are found in the ocean adhering to stones, bones, shells, &c. The corals were formerly believed to be vegetable substances hardened by the air; but are now known to be composed of a congeries of animals, endued with the faculty of moving spontaneously. The islands in the south-sea are mostly coral rocks covered over with earth. The little creatures, which have scarcely sensation enough to distinguish them from plants, build up a rocky structure from the bottom of that sea, too deep to be measured by human art, till it reaches the surface. Some of the coralline islands appear to be much older than others; and it is probable that, as these submarine works are continually going on, new islands may by that means frequently be produced. M. De Peyssonel of Marseilles, seems to have been the first who threw a proper light upon the nature and productions of coral. Those bodies which the count de Marsigli imagined to be flowers, this ingenious naturalist discovered to be insects inhabiting the coral: for upon taking branches of it out of the water, the flowers, which proceeded from a number of white points, disappeared: but upon being again restored to the water, they again became perceptible. The holes in the bark are the openings through which the insects that form these substances for their habitation come forth: and those cavities which are partly in the bark, and partly in the substance, are the cells which they inhabit. When the insects are dead, they corrupt, and communicate to the water the smell of putrid fish. The milky juice of coral is the blood of the animal, and running along the furrows perceived upon the proper substance or body of coral, becomes fixed, and hard, and is changed into stone.

The coral insect, expands itself in water, and contracts itself in air, or when it is touched with the hand in water, or acid liquors are poured upon it. Broken branches of coral have been observed to fasten themselves to other branches, and have continued to grow; and this is the case when they are connected with detached pieces of rock and other substances, from which no nourishment could be derived.

There are properly but three kinds of coral; red, white, and black; the black is the rarest and most esteemed; but the red was formerly in great repute as a medicine. When coral is newly taken out of the sea, the small protuberances on its surface are soft, and yield, on being pressed, a milky juice which effervesces with acids.

CORALLINES in natural history, were formerly reckoned plants, but in the Linnæan system, are placed in the class zoophytæ, and defined to be submarine plants like bodies, consisting of many slender, finely divided, and jointed branches, or animals, growing in the form of plants, having their stems fixed to other bodies, which stems are composed of capillary tubes, whose extremities pass through a calcareous crust and open into pores on the surface. The branches are often jointed and always subdivided into smaller branches, which are either loose and unconnected, or jointed as if glued together. They are distinguished from plants, by their texture and hardness, they also yield in distillation volatile salt, and their smell, when turbid, resembles that of horns and other animal substances. The corallines are distributed into the vesiculated, tubular, celliferous, and articulated kinds.

CORCHORUS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 37th order, columneæ. There are 16 species; of which the most remarkable is the olitorius, an annual, and a native of Asia, Africa, and America. It rises with a round stalk, to nearly two feet in height. The flowers come out at the sides of the branches opposite to the leaves. They are composed of five small yellow petals, and a great number of stamina. This plant is sold by the Jews about Aleppo, and is therefore called Jews' mallow.

CORDAGE, a term used, in general, for all sorts of cord, whether small, middling, or great, made use of in the rigging of ships.

CORDIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. There are five species, of which the principal are,

1. The myxa, or Assyrian plum, grows wild in Assyria or Egypt, and also on the coast of Malabar. It rises to the height of a middling plum-tree. The flowers are produced in bunches, and are white. The germen is roundish, and swells to a plum of the same form, and about the size of a damson, of a dark brown colour, a sweet taste, and very glutinous.

2. The sebestena, or rough leaved cordia, is a native of both the Indies, and sends forth several shrubby stalks eight or ten feet high. The plums are much of the shape of those of the myxa. The fruit of this tree is less valuable than the wood, a small piece of which thrown upon a clear fire will perfume a room with a most agreeable odour.

CORDIAL, in medicine, whatever raises the spirits, and gives them a sudden strength and cheerfulness.

CORDON, in fortification, a row of stones, made round on the outside, and set between the wall of the fortress which lies aslope, and the parapet which stands perpendicular.

COREOPSIS, tickseeded sunflower: a genus of the polygamia frustranea order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There are 20 species, most of them herbaceous perennials. They rise from three to eight feet in height; terminated by clusters of compound radiated flowers of a yellow colour. The flowers are all shaped like sunflowers, but smaller, and are very ornamental.

CORIANDRUM, *coriander*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. There are only two species, both of them herbaceous annuals, the leaves of which are useful for the kitchen, and the seeds are used in medicine. Both species have divided small leaves, resembling parsley: but there is only one species generally culti-

vated, namely, the sativum. This has a small fibrous white root, crowned by many parted leaves, having broadish segments; and in the centre an upright, branchy stalk, two feet high, having all the branches terminated by umbels of flowers, which are succeeded by globular fruit. It is propagated by seed, which ought to be sown in March. The seeds are recommended as carminative and stomachic.

CORIARA, the *tanner's* or *myrtle-leaved sumach*, a genus of the decandria order, in the diœcia class of plants, and in the natural method ranking under the 54th order, miscelaneæ. There are three species, the myrtifolia, rusufolia, and the sarmentosa. The first two are natives of the south of France, but the last is most commonly cultivated in this country.

CORIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the doubtful order. There is only one species, viz. the monspeliensis, or blue maritime coris. There are two varieties of this plant, one with a red, and the other with a white flower; but these are only accidental, and arise from the same seeds. They grow wild about Montpelier, and in most places in the south of France.

CORISPERMUM, *tickseed*, a genus of the digynia order, in the monandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There are two species; but neither of them is remarkable.

CORK. See QUERCUS.

CORK-FOSSIL, a name given to a kind of stone. It is a species of amianthus, consisting of flexible fibres loosely interwoven, and somewhat resembling vegetable cork. It is the lightest of all stones; it is fusible, and forms a black glass.

CORN, in country affairs, the grain or seeds of plants separated from the spica or ear, and used for making bread.

It is against the common law of England to buy or sell corn in the sheaf, before it is thrashed and measured: the reason whereof seems to be, because by such sale, the market is in effect forestalled.

CORN, in medicine and surgery, a hard tumour like a flat wart, growing in several parts of the feet, especially upon the joints of the toes. This disorder is not unjustly attributed to the wearing of narrow-toed shoes.

CORNEA *tunica*, in anatomy, the second coat of the eye; so called from its substance, which resembles horn.

CORNET, in the military art, signifies a commissioned officer in a troop of horse or dragoons.

CORNUCOPIÆ, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The involucrum is monophyllous, funnel-shaped, crenated, and multiflorous; the calyx bivalved; the corolla one-valved. There are two species.

CORNUS, *cornel-tree*, *cornelian cherry*, or *dogwood*; a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellatæ. Of this genus there are 12 species; the most remarkable are the following: 1. The mas or cornelian cherry-tree, has an upright tree stem, rising 20 feet high, and bearing small umbels of yellowish-green flowers, and succeeded by small, red, cherry-like, eatable, acid fruit. 2. The sanguinea, bloody twig, or common dogwood, has an upright stem, branching 10 or 12 feet high, having blood-red shoots, with oblong pointed leaves; all the branches are terminated by umbellate white flowers, succeeded by black berries. 3. The Florida or Virginian dog-wood, rises 12 or 15 feet high. Of this species there are several varieties, chiefly distinguished by the colour of their berries, which are red, white, or blue.

CORNUITA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There ar[illegible]wo species: the principal of which is, the p[illegible]midata; it has blue pyramidal flowers and hoary leaves. It grows plentifully in several of the islands of the West Indies. It rises to the height of 10 or 12 feet, with rude branches, the leaves being placed opposite. The flowers are of a fine blue colour.

COROLLA, among botanists, the most conspicuous part of a flower, surrounding the organs of generation. See BOTANY.

COROLLARY, is a consequence drawn from something already advanced or demonstrated.

CORONA, among botanists, expresses any thing growing on the head of a seed.

CORONA *borealis*, the northern crown or garland, in astronomy, a constellation of the northern hemisphere.

CORO[illegible], an ancient officer of the kingdom, and so called because he is wholly employed for the king and crown. In ancient times none under the degree of knight were chosen; but this qualification is now dispensed with. The Lord Chief Justice of the King's Bench is the sovereign coroner of the whole kingdom; but, under him there are two special coroners for each county. The duties of the coroner are, to inquire into the manner of death when any one is slain, or dies suddenly, or in prison. This inquiry must be made, *super visum corporis*, at the very place where the death happened, and in presence of a jury of four, five, or six, or more of the inhabitants of the neighbouring towns. If any person be found guilty of murder by this inquest, the coroner must commit him to prison for trial, and inquire also concerning his lands, goods, and chattels, which are forfeited thereby. It is also the duty of the coroner to inquire concerning shipwrecks, and treasure-trove. Although there are some honourable exceptions, yet it must be allowed that the office of coroner has fallen into great disrepute, since, instead of being filled by men whose circumstances place them beyond the influence of interested motives, it is occupied by characters who have no other view in serving than the emoluments of the office.

CORONILLA, jointed podded colutea, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. There are 14 species, all plants of considerable beauty with bright yellow flowers, but the principal is the emerus. This species rises with a shrubby stem, six or eight feet high. The leaves of this plant are esteemed laxative, and used as a substitute for common senna

in some parts of Europe. A dye is procured by fermentation from the leaves, like that of indigo.

CORPORAL, an officer under a serjeant, in a company of foot, who has charge over one of the divisions, places and relieves sentinels, and keeps good order in the corps-de-garde: he also receives the word from the inferior rounds which pass by his corps-de-garde. There are generally three corporals in each company.

CORPORATION, a body politic, or incorporate, so called because the persons or members are joined into one body, and are qualified to take and grant, &c. Corporations are either spiritual or temporal: spiritual, as bishops, deans, archdeacons, parsons, vicars, &c. Temporal, as mayor, commonalty, bailiff, burgesses, &c. And some corporations are of a mixed nature, composed of spiritual and temporal persons, such as heads of colleges and hospitals, &c.

Corporations may be established three different ways, viz. by prescription, letters patent, or act of parliament; but are most commonly established by patent or charter.

A corporation may be dissolved; for it is created upon a trust, and if it be broken, it is forfeited.

CORPUSCULAR *philosophy*, that way of philosophising which endeavours to explain things, and to account for the phenomena of nature by the motion, figure, rest, position, &c. of the corpuscles, or the minute particles of matter.

Boyle reduces the principles of the corpuscular philosophy to the four following heads.

1. That there is but one universal kind of matter, which is an extended, impenetrable, and divisible substance, common to all bodies, and capable of all forms. On this head, Newton remarks thus: "All things considered, it appears probable to me, that God in the beginning created matter in solid, hard, impenetrable, moveable particles; of such sizes and figures, and with such other properties, as most conduced to the end for which he formed them; and that these primitive particles, being solids, are incomparably harder than any of the sensible porous bodies compounded of them; even so hard as never to wear or break in pieces; no other power being able to divide what God made one in the first creation.

2. That this matter, in order to form the vast variety of natural bodies, must have motion in some, or all its parts; and that this motion was given to matter by God, the creator of all things; and has all manner of directions and tendencies. "These corpuscles," says Newton, "have not only a vis inertiæ, accompanied with such passive laws of motion as naturally result from that force; but also are moved by certain active principles; such as that of gravity, and that which causes fermentation, and the cohesion of bodies."

3. That matter must also be actually divided into parts; and each of these primitive particles, fragments, or atoms of matter, must have its proper magnitude, figure, and shape.

4. That these differently sized and shaped particles, have different orders, positions, situations, and postures, from whence all the variety of compound bodies arises.

CORRECTION, in printing, the pointing out or discovering the faults in a printed sheet, in order to be amended by the compositor, before it be printed off. See PRINTERS, *marks of*.

CORRELATIVE, something opposed to another in a certain relation. Thus, father and son are correlatives. Light and darkness, motion and rest, are correlative and opposite terms.

CORROSION, the action of gnawing away, by degrees, the continuity of the parts of bodies. Acids corrode most natural bodies.

CORROSIVES, in surgery, are medicines which corrode whatever part of the body they are applied to; such are burnt alum, white precipitate of mercury, white vitriol, red precipitate of mercury, butter of antimony, and lapis infernalis.

CORTUSA, *bear's ear sanicle*, a genus of the monogynia order, in the pentandria class of plants, ranking in the natural method under the 21st order preciæ. There are two species; both low, flowery, herbaceous perennials, having wheel-shaped flowers of a fine red colour. They are natives of mountainous countries.

CORUNDUM, a mineral, of which there are two species, the perfect and imperfect. Perfect corundum or sapphire is found in the East Indies, especially in Pegu and the island of Ceylon: and it is most commonly crystallized The crystals are of no great size; their primitive form, is a rhomboid whose angles are 86° and 94°.

It causes only a single refraction. Specific gravity, from 3.7 to 4.2. Colour, most frequently blue; sometimes red, purple, yellow, and green, and sometimes colourless; imperfect corundum is usually crystallized; sometimes found in amorphous masses; colour grey, often with various shades of blue and green.

CORUSCATION, a glittering or gleam of light issuing from any thing. It is chiefly used for the electrical fluid when rendered visible, as in a flash of lightning, &c.

CORVUS, the raven or crow kind, in ornithology; a genus of birds of the order of picæ, the distinguishing characteristics of which are these: the beak is convex and cultrated; the nostrils are covered with bristly feathers; the tongue is forked and cartilaginous; and the feet are of the walking kind. According to some naturalists there are 41 species; but Gmelin has enumerated 48. The most remarkable are the following.

1. The corax, or raven of English authors, weighs three pounds, and is about two feet two inches in length; the colour is black, finely glossed with a rich blue, the belly excepted, which is of a dusky colour. They are very docile birds, and may be trained up to fowling like hawks, or to fetch and carry like spaniels; they may be taught to speak like parrots; and even to imitate the human voice in singing. They have a great propensity to pilfer, often hiding things of value, to the great loss of the owner, without use to themselves. Their scent is remarkably good, and they are very long-lived.

2. The corone, or carrion crow, is very similar to the raven in habits and colour, but is only about half its size. It is not so frequently to be met with as the preceding.

3. The frugilegus, or rook, is the corvus of

Virgil; no other species of this kind being gregarious. It differs but little in its form from the carrion-crow: the most remarkable difference is in the nostrils and root of the bill; which parts in the crow are well clothed with feathers, but in the rook are bare or covered only with some bristly hairs. Besides insects, it also feeds on all sorts of grain, and instead of being of inconvenience, it is of service to the husbandman in destroying the maggot of the chafer-beetle, which, in some seasons, destroys whole crops of corn by feeding on the roots. The rook is a gregarious bird, sometimes being seen in immense flocks, so as almost to darken the air.

3. The monedula, or jackdaw. These birds are about the size of a small pigeon, though not quite so thick. They rarely build their nests in trees, preferring the ruins of human habitations, or of churches and towers, where their eggs and young are more beyond the reach of depredating school-boys. They sometimes lay in rabbit holes. They are domesticated with great facility, and may be taught to utter a considerable number of words. They are much addicted to pilfering, hiding not only their food, but a variety of toys and trinkets, a circumstance which has not unfrequently brought suspicion and disgrace upon the most honest domestics.

4. The glandarius, or jay. The jay weighs about seven ounces, and is about thirteen inches long. Its colours are beautifully arranged, by which it attracts attention, but its voice is harsh and chattering. Its nest is built of sticks, roots, and tender twigs, in the woods. Jays feed on almost all sorts of seeds and fruits, on nuts and acorns, and occasionally on eggs and even chickens. They will imitate with great ease and accuracy a variety of sounds, and articulate a considerable number of words, and, by this acquired talent, have sometimes produced considerable mischief. The jay is not found in the south, beyond Greece or Italy, and is unknown in Ireland.

5. The pica, or magpie. This bird is extremely common in England, and is found in most countries between Sweden and Italy in Europe. In America it is rare, and is a bird of passage. Though its colours consist only of black and white, yet the plumage of one seen in a perfect state of nature will excite a very high sensation of beauty. The pica may easily be brought up in a state of domestication, and will speak with great ease many phrases with all the readiness of the parrot, though not with his distinct and accurate enunciation. It constructs its nest with peculiar dexterity, not only covering the bottom with materials of a soft and downy texture, for the comfort of its young, but fixing the entrance at the side, and wattling a complete roof for its habitation, which is thus rendered warm, dry, and secure.

6. The graculus, or red-legged crow, is common on the coasts of Devonshire and Cornwall; and is to be found in Kent, Wales, and Scotland also. It is a turbulent, bold, and clamorous bird, builds in rocky situations, is voracious, and often seen snatching from its companions locusts or juniper berries, which constitute its favourite food. It is fond of glare, and has been known to snatch up burning sticks from the hearth, and place them in situations where, if unobserved, they must have produced destructive conflagrations.

CORVUS, the raven, in astronomy, a constellation of the southern hemisphere, wherein, according to Ptolemy and Tycho's Catalogue, are seven stars; whereas the Britannic Catalogue reckons

CORYLUS [illegible] hazel, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. There are three species with many varieties, C. avellana, common hazel nut tree, is properly a shrub, the trunk of which is covered with a whitish bark, which is smooth on the branches, frequently of a bay colour, spotted with white; the shoots are sometimes hairy, ash-coloured, and green, with white tubercles. The male catkins appear in autumn, and wait for the expansion of the female germs in spring; the styles are of a bright red colour, long, and setaceous; the flowering branches, especially those which bear the fertile flowers, are set with short fine hairs, terminating in globules; the catkins are in pairs, and of a yellowish-green colour.

CORYMBIUM, a genus of the monogamia order, in the syngenesia class of plants, in the natural method ranking under the 49th order, compositæ. There are four species.

CORYMBUS, properly denotes a cluster of ivy berries. Among botanists, it is a mode of flowering, in which the lesser flower stalks are produced along the common stalk on both sides, rising to the same height.

CORYPHA, mountain palm, or umbrella-tree, a genus of the order of palmæ, belonging to the monœcia class of plants. The corolla is tripetalous; the stamina six, with one pistil; the fruit a monospermous plum. There are two species. The umbracula is a native of the West Indies, where it is called codda pana.

CORYPHÆNA, in ichthyology, a genus belonging to the order of thoracici. There are 12 species, most of them natives of foreign seas. The most remarkable are the blue and parrot fishes, described by Mr. Catesby. The head of the first is of an odd structure, resembling that of the spermaceti whale: the mouth is small, each mandible armed with a single row of even teeth, so closely joined that they seem entire bones; the iris of the eye is red. On the back is a long fin, indented on the edge; behind the gills are two fins, one under the abdomen and another behind the anus. The tail is forked; and the colour of the whole fish is entirely blue. They are taken on the coasts of the Bahama islands, and in most of the seas between the tropics.

COS, the *whetstone*, in natural history, a genus of vitrescent stones, consisting of fragments of an indeterminate figure, sub-opaque and granulated. Of this genus there are several species, some consisting of rougher and others of smoother, or even of altogether impalpable, particles; and used not only for whetstones, but also for mill-stones and other similar purposes.

Cos *Turcica, Turkey-stone*, a species of stones of the garnet kind, belonging to the siliceous class. It is of a dull white, and often of an unequal colour; some parts appearing more compact than others.

CO-*secant*, in geometry, the secant of an

arch which is the complement of another to 90°.

Co-*sine*, in trigonometry, the sine of an arch, which is the complement of another to 90°.

COSMOGRAPHY, a description of the *several parts of the visible world; or the art of delineating the several bodies according to their magnitudes, motions, relations, &c.* It consists of two parts, astronomy, and geography.

COSSACKS, or *Cosaks*, a military nation inhabiting the frontiers of the Russian empire, and constituting the principal defence against the incursions of the Tartars and other savage tribes.

COSTUS, in botany, a genus of the monandria-monogynia class of plants, the flower of which consists of three lanceolated, concave, equal petals, placed erect; the fruit is a roundish capsule, with three cells, containing several triangular seeds. There are three species. The root of this plant, or the costus Arabicus is given in obstructions of the menses, and in chronic cases, in which there are infarctions of the viscera.

CO-*tangent*, the tangent of an arch, which is the complement of another to 90°.

COTTON, a soft downy substance found on the gossypium, or cotton-tree. Cotton is separated from the seeds by a mill, and then spun and prepared for all sorts of fine work. The finest sort comes from Bengal and the coast of Coromandel. Cotton forms a very considerable article in commerce, and is distinguished into cotton-wool and cotton-thread.

Cotton, *manufacture of.* It will not be expected by those of our readers who have any knowledge of the nature of this most extensive branch of the commerce of Great Britain, that we should here enter into a description of the vast and ingenious machinery employed in the manufacture of cotton; even an outline of the subject would far exceed our limits. From the simple method of spinning by the domestic machine called the one thread wheel, which, during a long period, was the only method used in this country, improvements in machinery succeeded each other, notwithstanding the outrageous opposition of the labouring classes, with such rapidity that, at the present time, such is the perfection which this one branch of mechanics has attained, and such the progress that has been made in the application of it, Britain has nothing to fear from the ingenuity of her most powerful rivals. Many years must elapse before she can be equalled in the present stage of her progress; and she never stands still. Among those who deserve to have their names enrolled as valuable contributors to this great source of national wealth, the most prominent are those of Hargreaves, Arkwright, Crompton, Kelly, and Watt. It would be injustice to omit noticing here how much the *execution* of the most improved machinery is indebted to the skilful management of the persons who use it: a circumstance which is chiefly to be attributed to the noble efforts of such men as Birbeck, Ure, and others, to render workmen acquainted with the principles of the processes which it is their business to conduct.

COTTUS, or *Bull-head*, in ichthyology, a genus belonging to the order of thoracici. The head is broader than the body, and the gill-membrane has six rays. There are ten species, of which the principal is the gobio, the river bull-head. This is about five inches long when full grown, is found in almost every part of Europe in clear streams, and conceals itself *under a stone, or in the gravel. Its food consists of worms, aquatic insects, and extremely young fish. It is said to deposit its spawn in* a hole in the gravel formed by it for the purpose, and which nothing but necessity will induce it to leave. It is capable of swimming very vigorously and rapidly, but is far more stationary than active in its habit. It is used as food, but almost exclusively by the poor. The mailed bull-head, or cataphractus, is found in abundance in the seas of Europe.

COTYLEDON, *navel-wort*; a genus of the pentagynia order in the decandria class of plants; and in the natural method ranking under the 13th order, succulentæ. There are 19 species, most of them succulent perennials for the green-house; though some require to be kept in a stove. They rise from half a foot to a yard and a half high, and are adorned with yellow flowers growing in umbels.

COUCH, in painting, a term used for each lay or impression of colour, either in oil or water, with which the painter covers his canvas, wall, wainscot, or other matter to be painted.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his head raised.

COUCHE', in heraldry, denotes any thing lying along: thus, chevron couche is a chevron lying sideways, with the two ends on one side of the shield, which should properly rest on the base.

COUCHING *of a cataract*, in surgery, one of the two chief methods of curing a cataract, by couching with the needle.

COVENANT, the agreement or consent of two or more by deed in writing, sealed and delivered; whereby either, or one of the parties, promises to the other, that something is done already, or shall be done afterwards.

A covenant is generally either in fact, or in law. In fact, is that which is expressly agreed between the parties, and inserted in the deed. In law, is that covenant which the law intends and implies, though it be not expressed in words.

CO-*versed sine*, in geometry, the remaining part of the diameter of a circle, after the versed sine is taken from it.

COVERT-*way*, or *Corridor*, in fortification, a space of ground, level with the field, on the edge of the ditch, three or four fathoms broad, ranging quite round the half-moons, and other works toward the country.

COVERTURE, in law, is applied to the condition of a married woman, who by the laws of this realm is sub potestate viri, and therefore disabled to make bargain with any, to the prejudice of herself or her husband.

COUGH, *tussis*, in medicine, a convulsive motion of the diaphragm, muscles of the larynx, thorax, and abdomen, violently shaking, and expelling the air that was drawn into the lungs by inspiration.

COULTER, in husbandry, an iron instrument fixed in the beam of a plough, and serving to cut the edge of each furrow. See Plough.

COUNCIL, or **Counsel**, *in a general sense, an assembly of divers considerable persons to concert measures relating to the state.*

COUNSELLOR *at law*, a person retained by a client to plead his cause in a public court of judicature. There are two degrees of counsel, viz. barrister and serjeants. Barristers are called to the bar after a certain period of standing in the inns of courts.

COUNT, a nobleman who possesses a domain erected into a county. The dignity is a medium between that of a duke and a baron.

Count *wheel*, in the striking part of a clock, a wheel which moves round once in 12 or 24 hours. It is sometimes called the locking-wheel.

COUNTER *barry* or **Contre** *barre*, in heraldry, is the same as our bendy sinister per bend counterchanged.

Counter *bond*, a bond of indemnification, given to one who has given his bond as a security for another's payment of a debt, or the faithful discharge of his office or trust.

Counter *changed*, in heraldry, is when any field or charge is divided or parted by any line or lines of partition, consisting all interchangeably of the same tinctures.

Counter *deed*, a secret writing either before a notary or under a private seal, which destroys, invalidates, or alters a public one.

Counter *ermine*, in heraldry, is the contrary to ermine, being a black field with white spots.

COUNTERFEITS, in our law, are persons that obtain any money or goods by counterfeit letters or false tokens, who being convicted before justices of assize, or of the peace, &c. are to suffer such punishment as shall be thought fit to be inflicted, under death, as imprisonment, pillory, &c.

COUNTERMARCH, in military affairs, a change of the face or wings of a battalion, by which means those that were in the front come to be in the rear. It also signifies returning or marching back again.

Counter-mine, in war, a well and gallery driven and sunk till it meets the enemy's mine, to prevent its effect.

Counter-paled, *contre palle*, in heraldry, when an escutcheon is divided into 12 pales, charged per fesse, the two colours being countercharged.

Counter-part, in music, denotes that one part is to be applied to another. Thus the bass is said to be the counterpart to the treble. In law, it is the duplicate, or copy of an indenture or deed.

Counterscarp, in fortification, is the exterior slope of the ditch, though it is often taken for the covered way and glacis. *Angle of the counterscarp* is that made by its two sides meeting before the middle of the curtain.

COUPLE *close*, in heraldry, the fourth part of a chevron, never borne but in pairs, except there be a chevron between them, saith Guillim, though Bloom gives an instance to the contrary.

COURSE, in navigation, that point of the compass or horizon on which the ship steers, or the angle between the rhumb-line and the meridian. See **Navigation**.

Course, in architecture, *a continued range of stones, level, or of the same height throughout the whole length of a building, without* being interrupted by any aperture.

Courses, in a ship, the mainsail and foresail: when the ship sails under them only, without lacing on any bonnets, she is said to go under a pair of courses. To sail under a main course and bonnets, is to sail under a mainsail and bonnet.

COURT. A court is a place appropriated to the judicial administration of justice.

The most general division of our courts is into such as are of record, or not; those of record are again divided into such as are supreme, superior, or inferior.

The supreme court of this kingdom is the high court of parliament, consisting of the king, lords, and commons, who are vested with an absolute authority in making laws, and repealing and reviving old ones.

Superior courts of record are the House of Lords, the chancery, king's bench, common pleas, and exchequer: the less principal ones are such as are held by commission of gaol-delivery, oyer and terminer, assize, nisi-prius, &c.

The inferior courts of record, are corporation courts, courtsleet, and sheriff's torn, &c.

Courts not of record, are the courts-baron, county-courts, hundred-courts, &c. Also the admiralty and ecclesiastical courts, which are not courts of record, but derive their authority from the crown, and are subject to the controul of the king's temporal courts where they exceed their jurisdiction.

Court-baron is a court which every lord of the manor has within its own precincts. This court is an inseparable ingredient of every manor; and if the number of the suitors should so fail as not to leave sufficient to make a jury or homage, that is, two tenants at least, the manor is lost. The court-baron may inquire into the death of tenants, nuisances, wastes, forfeitures, and the like; and the punishment is by amercement.

Court *of chancery*. See **Chancellor**.

COUSIN, a term of relation between the children of brothers and sisters, who in the first generation are called cousins-german, in the second generation, second cousins, &c.

COUSU, in heraldry, a piece of another colour or metal so placed on the ordinary as if sewed thereon.

COW, in zoology, the female of the ox kind. See **Bos**.

CRAB'S *claws*. See **Materia Medica**.

Crab's *eyes*. See **Pharmacy**.

Crab, an engine of wood, with three claws, placed on the ground like a capstan, and used at launching, or heaving ships into the dock.

CRADLE, in surgery, a case in which a broken leg is laid after being set.

Cradle, among shipwrights, a timber frame made along the outside of a ship by the bilge, for the convenience of launching her with ease and safety.

CRAFT, in the sea language, signifies all manner of nets, lines, hooks, &c. used in fishing. Hence all such little vessels as ketches, hoys, and smacks, &c. used in the fishing trade, are called small craft.

CRAMBE, *sea cabbage, sea kale*, or *sea*

colewort, a genus of the siliquosa order, in the tetradynamia class of plants, ranking in the natural method under the 39th order, siliquosæ. There are six species, three herbaceous esculents with perennial roots, producing annually large leaves, like those of the cabbage, spreading on the ground with yellow flowers. Only one species is a native of Britain, and it grows wild in several parts of the sea-coast. It is propagated by seeds sown in common light earth in autumn or spring. The crambe fruticosa is a green house plant.

CRAMERION, a genus of the monogynia order, in the tetrandria class of plants.

CRAMPONEE, in heraldry, a cross which has at each end a cramp or square piece coming from it.

CRANE. See GRUS.

CRANE, in mechanics, signifies a machine for raising and lowering heavy bodies and large weights, and removing them from one place to another within the sweep of its arm, which revolves on a centre.

The parts of a crane are, the post or upright, which is either moveable or turns upon pivots; the gib, an arm extending from the upper part of the post; and the stay, intended for a support to the gib, and fixed in a diagonal direction from the gib to the bottom of the post. These with the requisite wheels, pullies, and levers, complete the crane.

Mr. James Ferguson appears to have been the first who introduced any improvement of importance in the construction of cranes. His crane with three trundles, having different numbers of stones, is well known. Cranes have been generally constructed of timber; but cast and unrought iron have been lately introduced, and with decided advantage; both as it regards the effects which the weather must always be expected to produce on such machines; and also as it respects the combination of its parts in having the strength duly proportioned, and in adapting its formation to any situation or circumstance. The greatest improvement in the construction of cranes is due to Mr. Bramah, who has ingeniously contrived to connect with them the almost boundless power of the hydraulic press.

CRANICHIS, a genus of the class and order gynandria decandria. The essential character is, nectary galeated. There are five species.

CRANIOLARIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There is one species, a native of New Spain, but not possessed of any remarkable property.

CRANK, a contrivance in machines, in manner of an elbow, only of a square form, projecting from a spindle, and serving by its rotation to raise and lower the pistons of engines.

CRANK likewise denotes the iron support for a lantern, and also the iron made fast to a stock of a bell for ringing it.

CRANZIA, a genus of the pentandria monogynia class and order. There is one species, a native of the East Indies.

CRAPE, a light transparent stuff, in manner of gauze: made of raw silk gummed and twisted on the mill, woven without crossing, and much used in mourning. The invention of this stuff came originally from Bologna; but, till of late years, Lyons is said to have had the chief manufacture of it.

CRASPEDIA, a genus of the class and order syngenesia polygamia segregata. There is one species, a native of New Zealand.

CRASSULA, lesser orpine, or live-ever; a genus of the pentagynia order, in the pentandria class of plants; and in the natural method ranking under the 13th order, succulentæ. There are 64 species, all of them natives of warm climates. Several of them are cultivated in this country, but require the assistance of artificial heat for their preservation.

CRATÆGOS, wild service-tree, hawthorn, &c. a genus of the digynia order, in the icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. There are 23 species. This genus consists chiefly of shrubs or trees, hardy and deciduous; leaves simple, undivided, or lobed; peduncles in most species many flowered; corymbed terminating, and solitary from the axils; corollas white, appearing in May and June, and succeeded by red berries in autumn.

CRATER, in astronomy, a constellation of the southern hemisphere, consisting of seven stars according to Ptolemy's Catalogue, of eight in Tycho's, and eleven in the Britannic Catalogue. The term is also used to signify the mouth or opening of a volcanic mountain.

CRATEVA, the garlic pear; a genus of the monogynia order in the dodecandria class of plants; and in the natural method ranking under the 25th order, putamineæ. There are five species, natives of both Indies. They are of the tree kind; and are chiefly distinguished by their fruit. The tapia, or garlic pear, has a smooth round fruit about the size of an orange, with a hard brown shell or cover, which incloses a mealy pulp, filled with kidney-shaped seeds. It has a strong smell of garlic. The marmelos grows to the size of a very large tree, with trifoliate leaves. The flowers have the smell of roses, and are succeeded by an oblong fruit of the size of an apple, covered with a very hard bony shell, and containing a soft fleshy pulp, having the taste of quinces. From the flowers of this plant is obtained by distillation a water highly odoriferous and cordial; and the pulpy part of the fruit is prepared into various kinds of marmalades.

CRAX, in ornithology, the curasson, a genus of birds belonging to the order of gallinæ. The base of the beak of each mandible is covered with wax; and the feathers of the head are curled. There are five species, viz. 1. the alecator, or Indian hen of Sloane, is about the size of a small turkey. They are frequent at Guiana, and form a very considerable article of food to the inhabitants. 2. The rubra, or Peruvian hen, is red, with a bluish head. These birds are natives of Mexico and Peru. They are frequently kept tame in our menageries in England, and readily mix with other poultry, feeding on bread and grain. 3. The mitu, or Brazilian pheasant, is black, with a dusky belly; it is a native of Guinea and Brazil. 4. The globicera, has a yellow protuberance between the nostrils, and is of a bluish black colour: it is likewise a native of Brazil. 5. The pauxi, or Mexican phea-

sant of Brisson, is of a bluish colour, with blue wax, and the tip of the tail and belly white.

CRAY-FISH, or CRAW-FISH. See CANCER.

CRAYONS, are coloured substances, which naturally possess, or are reduced by art, to the texture of chalk; they are used for sketching and painting in their dry state, in the form and manner of a black lead pencil. As crayons may be obtained of any requisite colour, and prepared in the very best manner at any of the respectable colour shops, it is unnecessary to give directions here for their preparation. Crayon painting is generally executed on strong blue paper, which should be freed from its knots by cutting them with a sharp knife, or rubbing them down with a piece of flat pumice-stone.

After this is done the paper must be pasted very smooth on a linen cloth, previously strained on a deal frame, the size according to the artist's pleasure: on this the picture is to be executed: but it is most eligible not to paste the paper on till the whole subject is first dead-coloured. The method of doing this is very easy, by laying the paper with the dead-colour on its face, upon a smooth board or table, when, by means of a brush, the back of the paper must be covered with paste; the frame with the strained cloth must then be laid on the pasted side of the paper; after which turn the painted side uppermost, and lay a piece of clean paper upon it, to prevent smearing it: this being done, it may be stroked gently over with the hand; by which means all the air between the cloth and the paper will be forced out.

When the paste is perfectly dry, the student may proceed with the painting. The advantages arising from pasting the paper on the frame according to this method, after the picture is begun, are very great, as the crayons will adhere much better than in any other way; which will enable the student to finish the picture with a firmer body of colour, and greater lustre.

CREAM. See MILK.

CREAM *of tartar*, the common name of supertartrate of potash; it is also denominated crystals of tartar. In this salt there is an excess of the TARTARIC acid, which see.

CREPIS, bastard hawk-weed, a genus of the polygamia order, in the syngenesia class of plants, and in the natural method ranking under the forty-ninth order, compositæ. There are twenty species, most of them herbaceous annuals, rising to the height of a foot or a foot and a half, and having their branches terminated by compound red and yellow flowers. These are very large, and consist of many flat florets, which are succeeded by plenty of seed, which, if permitted to fall on the ground, will produce a number of young plants without further trouble.

CREPITATION, that noise which some salts make over the fire in calcination, called also detonation.

CREPUSCULUM, in astronomy, twilight: the time from the first dawn or appearance of the morning to the rising of the sun; and again, between the setting of the sun and the last remains of day. The crepusculum is computed to begin and end when the sun is about eighteen degrees below the horizon. It is of longer duration in the solstices than in the equinoxes, and longer in an oblique than in a right sphere. The crepuscula are occasioned by the sun's rays refracted in our atmosphere.

CRESCENT, in heraldry, a bearing in form of a new moon.

CRESCENTIA, the calabash tree; a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 25th order, putamineæ.

There are two species, viz. 1. The cujete, narrow leaved calabash-tree. 2. The cucurbitina broad leaved calabash tree. These are small trees, with large leaves, either singly, alternate, or in alternate bundles. Flowers on the trunk or branches sub-solitary; they are both natives of the West Indies.

CRESSA, in botany, a genus of plants of the class and order pentandria digynia. The essential character is calyx five leaved: corolla, salver-form; filaments sitting on the tube; capsule two valved. There are two species.

CREST, in armoury, the top part of the helmet, generally ornamental. In heraldry, it is that part of the casque or helmet next the mantle.

CRINODENDRUM, in botany, a genus of plants of the class and order monadelphia decandria. Calyx none, corolla bell-shaped, six petalled; capsula one celled, gaping at the top. It is a native of Chili.

CRINUM, a genus of the monogynia order, in the hexandria class of plants, ranking in the natural method under the 9th order, spathaceæ. It is a beautiful greenhouse plant, about three feet high, having large funnel-shaped flowers, blue, white, or striped, and a very fragrant smell. There are six species.

CRITICISM, from the Greek word κρινω, signifies, in general, the art of judging: but, in its more restrained and usual sense, denotes the art of judging with propriety concerning the nature of literary compositions.

CROCODILE. See LACERTA.

CROCUS, in botany, a genus of the triandria monogynia class and order. Natural order ensatæ. There are two species with many varieties, viz. C. officinalis, officinal crocus, or saffron, and C. vernus, or spring crocus.

CROISADE, CRUSADE, or CRUZADO, a name given to the expeditions of the Christians against the Infidels, for the conquest of Palestine; so called because those who engaged in the undertaking wore a cross on their clothes, and bore one on their standard.

CROMLECHS, in British antiquities, are huge, broad, flat stones, raised upon other stones set up on end for that purpose. They are common in Anglesea. They are supposed by some persons to have been tombs, though others imagine that they were altars for religious services.

CROSLET, in heraldry, is when a cross is crossed again at a small distance from each of the ends.

CROSS, in heraldry, is an ordinary composed of fourfold lines, whereof two are perpendicular, and the other two transverse. The content of a cross is not always the same; for when it is not charged, it has only the fifth part of the field.

CROSSELET, a little or diminutive cross,

used in heraldry, where the shield is frequently seen covered with crosselets.

CROSSOTYLUS, a genus of the polyandria order, in the monadelphia class of plants. There is one species, a native of the Society Isles.

CROTALARIA, *rattle-wort*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. There are 32 species, all of them natives of warm climates. They rise from eighteen inches to five feet in height, and are adorned with flowers of a red, blue, or yellow colour. The most remarkable species is the retusa. It is a native of the East Indies. The flowers are yellow; the pods smooth, and placed horizontally; they are filled with seeds, which, when dried, and shaken by the lightest wind, produce a rattling noise; and this, by the inhabitants of the countries where the plant is native, is attributed to the devil, who is thought to deliver his oracles in this whimsical manner.

CROTALUS, *rattle-snake*, a genus belonging to the order of amphibia serpentes, the generic character of which is, scuta on the abdomen; scuta and squamæ beneath the tail; rattle terminating the tail.

1. Crotalus horridus, or banded rattle-snake. The genus crotalus, or rattle-snake, affords the most signal examples of the powerfully destructive poison with which some of the serpent tribe are furnished.

This species is found, in general, from three to four or five feet in length: and is of a yellowish-brown colour; the head is large, flat, and covered with small scales; the rest of the upper parts with large oval ones. At the extremity of the tail is situated the rattle, consisting of several hard, dry, horny processes, and which, on the least disturbance or irritation, is elevated and shaken in such a manner as to cause a strong or brisk rattling sound.

2. Crotalus durissus, or striped rattle snake. This species may be distinguished from the former by the different disposition of its colours; being of a deep brown above, with pale yellow streaks forming a continued series of lozenges down the back. It is also a native of America. Its bite, appears to be equally fatal with that of the former species.

3. Crotalus dryinas, or wood rattlesnake. This is said to be of a paler tinge than the two former species, and variegated with yellowish marks on the back.

4. Crotalus miliarius, or miliary rattlesnake. It is of a grey-brown, shaded on the back with red, and marked by large black spots with white edges. This is the smallest species of rattlesnake yet known, rarely exceeding the length of two feet. In its general habits it resembles the preceding kinds.

CROTCHET, in music, one of the notes or characters of time, equal to half a minim, and double of a quaver. A dot added to the crotchet, increases its time by one-half. See Music.

Crotchets, marks or characters, serving to inclose a word or sentence, which is distinguished from the rest, being generally in the form [ ], or this ( ).

CROTON, *wild ricinus*, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. There are 53 species. The plants of this numerous genus are herbaceous, or more frequently shrubby. Leaves accompanied with stipules, generally alternate, seldom opposite: flowers axillary, or terminating usually in spikes; but sometimes in corymbs: the spikes are mostly monaecous. These plants are chiefly inhabitants of the East and West Indies.

CROTOPHAGA, in ornithology, a genus of birds belonging to the order of picæ. The most remarkable species is the ani, which is about the size of a blackbird: the colour of the whole bird is black, in some parts glossed with purple, and about the neck faintly tinged with green on the margins. This species is found in Jamaica, St. Domingo; also at Cayenne, and other parts of South America. Contrary to the custom of all other birds, they have the singularity of many lying in the same nest; to make which they all unite in concert, and, after laying their eggs, sit on them close to each other to hatch them, each striving to do the best for the general good: and when the young are hatched, the parents, without reserve, do their best to feed the whole flock.

CROUP *of a horse*, is the extremity of the reins above the hips.

CROW. See Corvus.

Crow, in mechanics, a kind of iron lever sharp at one end, and a claw at the other, used for heaving or pushing great weights.

CROWN, in heraldry, is used for the representation of that ornament, in the mantling of an armoury, to express the dignity of persons.

Crown, *the imperial*, is a bonnet or tiara, with a semicircle of gold, supporting a globe with a cross at top.

Crown, in architecture, the upper member of the cornice.

Crown, in astronomy, a name for two constellations, the one called borealis, the other meridionalis.

Crown, in geometry, a plane ring, included between two concentric perimeters, generated by the motion of part of a right line round the centre, to which the moving part is not contiguous.

The area of a crown is had by multiplying its breadth by the length of the middle periphery; for a series of terms in arithmetic progression being $n \times \frac{a+w}{2}$, *i. e.* the sum of the first and last multiplied by half the number of terms, the middle terms must be $\frac{a+w}{2}$; therefore, that multiplied by the breadth or sum of all the two terms will give the crown.

Crown-*wheel of a watch*, the upper wheel which by its motion drives the balance. In royal pendulums it is called the swing-wheel.

Crown-*work*, in fortification, an outwork having a large gorge, and two long sides terminating towards the field in two demi-bastions. It is intended to inclose a rising ground, or to cover an intrenchment.

CRUCIANELLA, petty madder, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. There are nine species, natives of the southern parts of Europe; but none of them possessed of any remarkable quality.

CRUCIBLE, a chemical vessel made of earth, and so tempered and baked as to endure the greatest fire. They are used to melt metals, and to flux minerals, ores, &c.

CRUIZERS, in naval affairs, vessels, employed on a cruize. They are, in truth, small men of war made use of to secure our merchants' ships and vessels from the enemy's small frigates and privateers. They are generally formed for sailing well, and are commonly well manned. The safety of the trade in the Channel requires that ships of this description should be kept out at sea.

CRUSTACEOUS *fish*, in natural history, those covered with shells, consisting of several pieces or scales, as those of crabs, lobsters, &c. They are generally softer than the shells of the testaceous kind, which consist of a single piece, and commonly thicker and stronger than the former; such as those of the oyster, scallop, cockle.

CRYPTOGAMIA, one of Linnæus's classes of plants, the organs of fructification of which are either concealed within the fruit itself, or so minute as to escape observation. It embraces 4 orders: filices, musci, algæ, and fungi, which see.

CRYPTOSTOMUM, a genus of the pentandria class and order. There is one species, a shrub of Guiana.

CRYSTAL, in natural history, the name of a very large class of fossils, hard, pellucid, and naturally colourless.

CRYSTALLIZATION. The word crystal *originally signified* ice; but it was afterwards applied to crystallized silica, or rock crystal. Chemists have applied the word to all transparent bodies of a regular shape; and at present it is employed to denote in general the regular figures which bodies assume when their particles have full liberty to combine according to the laws of cohesion. These regular bodies occur very frequently in the mineral kingdom, and have long attracted attention on account of their great beauty and regularity. By far the greater number of the salts assume a crystalline form; and as these substances are mostly soluble in water, we have it in our power to give the regular shape of crystals in some degree at pleasure.

All the substances with which we are acquainted may be divided into solid, liquid, and gaseous Crystals are obviously confined to the first set, the fluidity of the two last rendering them incapable of retaining a regular form; but many of them may be made to assume a solid state, and in that case they usually crystallize. Most solid bodies either occur in the state of crystals, or are capable of being made to assume that form. There is a particular form which every substance always affects when it crystallizes. Thus common salt is observed to assume the shape of a cube; and alum that of an octahedron, consisting of two four-sided pyramids, applied base to base. Saltpetre assumes the form of a six-sided prism: sulphat of magnesia, that of a four-sided prism; and carbonate of lime that of a rhomboid. This, however, is liable to considerable variations, according to the circumstances of the case; but there are a certain number of forms peculiar to every substance; and the crystals of that substance, in every case, adopt one or other of these forms, and no other.

As the particles of bodies must be at liberty to move before they crystallize, it is obvious that we cannot reduce any bodies to the state of crystals, except those which we are able to make fluid.

Solution is the common method of crystallizing salts. They are dissolved in water; the water is slowly evaporated; the saline particles gradually approach each other, combine together, and form small crystals; which become constantly larger by the addition of other particles, till at last they fall by their gravity to the bottom of the vessel. Or a saturated solution being prepared in hot water, it is set by to cool. On the escape of the caloric, by which the solution was in great part accomplished, the salt crystallizes. Such salts commonly form in groups, attached to the sides or bottom of the vessel, or depending from a pellicle. They usually contain more water of crystallization than the former class.

There are many substances, however, neither soluble in water nor other liquids, which, notwithstanding, are capable of assuming a crystalline form. This is the case with the metals, with glass, and some other bodies. The method employed to crystallize them is fusion, which is a solution by means of caloric alone. By this method particles are separated from one another; and if the cooling proceeds gradually, they are at liberty to arrange themselver in regular crystals.

As to the theory of crystallization it may be sufficient here to remark that Haüy, and other chemists of eminence, have assumed that the primitive molecules of matter have three distinct forms, viz. the tetraedron, the simple prism, and the cube; and that these figures form every crystal in nature, and by a certain arrangement with respect to each other, completely fill space. This theory has been found insufficient to account for all the phenomena attending the process of crystallization.

Dr. Wollaston, in order to obviate the difficulties thence arising, has ingeniously proposed to consider the primitive particles of matter as spheres, which, by mutual attraction, have assumed that arrangement which brings them as near as possible to each other. This, however, must be understood with limitation. Dr. Wollaston does not consider the particles as perfectly spherical, but, like Haüy, divides their forms into three classes, viz. the sphere, the spheroid, and the oblong sphere, or ellipsoid. Others are of opinion that the primitive particles of matter are perfectly spherical. This opinion was, we believe, originally advanced, and very ingeniously supported by Mr. Gurney in his lectures at the Surrey Institution.

Great attention has of late been paid to the measuring of the angles of crystals. The instrument used for this purpose is called a goniometer, of which there are two kinds.

1. The goniometer of M. Carangeau, used by M. Haüy, consists of two parallel blades, jointed like those of scissars, and capable of being applied to a graduated semicircular sector, which gives the angle to which the joint is opened, in consequence of the previous apposition of the two blades to the angle of the crystal. 2. The reflective goniometer of Dr. Wollaston; an admirable invention, which measures the angles of the minutest possible crystals with the utmost precision. An account

of this beautiful instrument may be found in the Phil. Trans. for 1809, and in Tilloch's Magazine for February 1810, vol. 35.

CUBÆA, in botany a genus of the decandria monogynia class and order. Calyx turbinated, five-parted, unequal, permanent; petals, five, unequal; filaments villose, three shorter; germen pedicelled; legume villose; six or seven seeded. There are two species.

CUBE, or hexahedron, a solid regular body, consisting of six equal square sides. It is supposed to be generated by the motion of a square plane along a line equal and perpendicular to one of its sides.

To determine the surface and solidity of a cube. Multiply one side by itself, which will give one square; this multiplied by 6 will give the whole surface. Also multiply one side twice by itself, that is, cube it, and that will give the solid content.

CUBES or *cubic numbers*, are formed by multiplying any numbers twice by themselves. Thus the cubes of 1, 2, 3, 4, 5, 6, &c. are 1, 8, 27, 64, 125, 216, &c.

CUBE, *duplication of the*, is the finding of the side of a cube that shall double in solidity a given cube. It cannot be done geometrically, as it requires the solution of a cubic equation, or the finding two mean proportionals. Let a be the side of the given cube, and z that of the double one, then $z^3 = 2a^3$, or $a^2 : z^2 :: z : 2^a$, therefore if a and z be the 1st and 2d terms of a set of continued proportionals, then $a^2 : z^2$ is the ratio of the square of the 1st to that of the 2d, which is the same as the ratio of the 1st term to the 3d, or the 2d to the 4th, or of z to 2^a; therefore, z being the 2d term, 2^a will be the 4th, so that z the side of the cube sought, is the 2d of 4 terms in continued proportion; the 1st and 4th being a and 2^a, *i. e.* the side of the double cube is the 1st of two mean proportionals between a and 2^a.

CUBE, or *cubic number*, in arithmetic, is that produced by the multiplication of a square number by its root.

CUBE *root of any number, or quantity*, such a number, or quantity, which, if multiplied into itself, and then, again, the product thence arising, by that number or quantity, being the cube root, this last product shall be equal to the number or quantity whereof it is the cube root; as 2 is the cube root of 8, because two times 2 are 4, and two times 4 are 8; and $a+b$ is the cube root of $a^3+3a^2b+3ab^2+b^3$.

CUBIT, in the mensuration of the ancients, a long measure, equal to the length of a man's arm, from the elbow to the tip of the fingers. Dr. Arbuthnot makes the English cubit equal to 18 inches; the Roman cubit equal to 1 foot, 5.406 inches; and the cubit of the Scripture equal to 1 foot, 9.888 inches.

CUCKOW. See CUCULUS.

CUCKOW *spit*. See CICADA.

CUCUBALUS, berry-bearing chickweed, a genus of the trigynia order in the decandria class of plants, and in the natural method ranking under the 22d order, caryophylei. There are 17 species; the most remarkable of which are,

1. The behen, Swedish lychnis, or gumsepungar, a native of several parts of Europe. The flower is curiously wrought like a network, and is of a purplish colour. The leaves have somewhat of the flavour of peas: the Gothlanders apply them to erysipelatous eruptions.

2. The catholicus, or night-flowering lychnis, grows naturally in Spain and Italy. It is a perennial plant, rising with an upright branching stalk, a foot and a half high. The flowers are closed all the day; but at night when the sun has left them, they expand, and emit an agreeable smell.

3. The otites, or catch-fly, is a native of Britain and other European countries. It has a thick, fleshy, perennial root, which strikes into the ground, whence rises a jointed stalk three or four feet high. At the joints there exudes a viscous clammy juice, that sticks to the fingers when handled; and the small insects which settle upon those parts of the stalks are so fastened that they cannot get off. The flowers are small, and of a greenish colour.

CUCUJUS, a genus of insects of the coleoptera order: antennæ filiform; feelers four, equal, the last joint truncate and thicker; lip short, bifid; the divisions linear and distant; body depressed. There are 11 species belonging to this genus.

CUCULLANUS, a genus of worms of the order intestina: body sharp, pointed behind and obtuse before; mouth orbicular, with a striated hood. They are most of them viviparous. There are eight species, which take their names from the animal in which they are found.

CUCULLARIS. See ANATOMY.

CUCULUS, the cuckow, in ornithology, a genus belonging to the order of picæ. There are 46 species. The most remarkable are:

1. The canorus, or common cuckow, weighs about five ounces, and is in length 14 inches, in breadth 25. The bill is black, and about two-thirds of an inch in length. The head, hind part of the neck, coverts of the wings and rump, are of a dove-colour, darker on the head and paler on the rump. The legs are short, and the toes disposed two backwards and two forwards, like those of the wood-pecker. This bird appears in our country early in the spring, and makes the shortest stay with us of any bird of passage. It takes its departure about the beginning of July. Some of these birds, however, have been found to winter in this island, taking up their abode in hollow trees, where they have lain in a torpid state. The cuckow does not rear her own offspring, but selects the nest of some other bird, particularly that of the hedge sparrow, in which she deposits her eggs. When the sparrow has sat her usual time, and disengaged the young cuckow, and some of her own offspring from the shell, her own young ones are soon turned out by the intruder, who remains in possession of the nest. There are many more male cuckows than females; for when five or six have been taken in a trap, not a female has been found among them. Cuckows may be brought up tame. They will eat bread and milk, fruit, insects and flesh. 2. The indicator or honey guide is a native of Africa, particularly in the interior parts from the Cape of Good Hope, where it guides by its note the persons who go in search of wild honey. 3. The capensis, or Cape cuckow, is somewhat smaller than the European. It also inhabits the Cape of Good Hope. 4. The honoratus or sacred cuckow, inhabits Malabar, and feeds on reptiles. The

inhabitants hold it in great veneration. 5. The vetula is larger than a blackbird, and is a native of Jamaica. It is very tame and easily taken. It feeds on lizards, frogs, small snakes, and young rats and birds. It is called the rain-bird, from its making a great noise before rain. 6. The cayanus, or Cayenne cuckow, is of the same size with the preceding. The inhabitants of Cayenne call it the devil, and account it a bird of bad omen.

CUCUMIS, in botany, a genus of the monœcia syngenesia class and order. Natural order of cucurbitaceæ. There are 13 species. These are all annual plants, with herbaceous scandent stems. The sativus, common cucumber, generally cultivated for the tables, is so well known, as not to require a particular description. The melo, common or musk melon, belongs to this genus. There is a great variety of this fruit cultivated in this country, especially by those who supply the markets, where their size is chiefly regarded, so that by endeavouring to increase their bulk, the fruit becomes of little value.

CUCURBITA, in botany, a genus of the monœcia syngenesia class and order. Natural order of cucurbitaceæ. There are seven species. The plants of this genus are very nearly allied to those of cucumis, and are distinguished from it chiefly by the swelling rim of the seed. Like them they are annual, with trailing herbaceous stems, furnished with tendrils for climbing.

CUIRASS, a piece of defensive armour, made of iron plate, well hammered, serving to cover the body from the neck to the girdle, both before and behind.

CULEX, the gnat, a genus of insects belonging to the order of diptera. The mouth is formed by a flexible sheath, inclosing bristles pointed like stings. The antennæ of the males are filiform; those of the females feathered. There are seven species. These insects are well known by the severe punctures they ininflict, and the itchings thence arising. Before they turn to flying insects, they have been in some measure fishes, under two different forms. "You may observe in stagnate waters," says Barbut, "from the beginning of May till winter, small grubs with their heads downward, and their hinder parts on the surface of the water; from which part arises sideways a kind of vent-hole, or small hollow tube like a funnel; and this is the organ of respiration. These larvæ retain their form during a fortnight or three weeks, after which period they turn to chrysalids. After three or four days the chrysalis passes to the state of a gnat. A moment before, water was its element; but now it becomes an aerial insect, and can no longer exist in water. The sting of the gnat is a tube, containing five or six spicula of exquisite minuteness; some dentated like the head of an arrow, others sharp-edged like razors. These spicula, introduced into the veins, act as pump-suckers, into which the blood ascends. The insect injects a small quantity of liquor into the wound, by which the blood becomes more fluid, and is seen through the microscope passing through these spicula. The pain occasioned by the string may be removed by washing the part affected with volatile alkali, or with a little vinegar. Gnats engender in the air. The female deposits her eggs on the water, placing them one by the side of another in the form of a little boat. This vessel, composed of two or three hundred eggs, swims on the water for two or three days, after which they are hatched. If a storm arises, the boats are sunk. Every month there is a fresh progeny of these insects. Were they not devoured by swallows, other birds, and by several carnivorous insects, the air would be darkened by them."

CULMINATION, in astronomy, the passage of any heavenly body over the meridian, or its greatest altitude for that day.

CULMUS, in botany, a straw, or haulm, the proper trunk of grasses which elevates the leaves, flower, and fruit.

CUMINUM, *cummin*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is ovate and striated; there are four partial umbels, and the involucra are quadrifid. There is but one species, viz. the cyminum. It is an annual plant, perishing soon after the seed is ripe. It rises nine or ten inches high in the warm countries, where it is cultivated, but seldom rises above four in this country.

CUNILA, in botany, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. There are four species, none of which has any remarkable property.

CUNNINGHAMIA, a genus of the tetrandria monogynia class and order. There is one species.

CUNONIA, a genus of the digynia order in the decandria class of plants, and in the natural method ranking with those of which the order is doubtful. There is one species, a native of the Cape.

CUOGOLO, in natural history, the name of a stone much used by the Venetians in glass making, and found in the river Fesino. It is a small stone of an impure white, of a shattery texture, and is of the shape of a pebble.

CUP-*galls*, in natural history, a name given by authors to a very singular kind of galls, found on the leaves of the oak and some other trees. They are of the figure of a cup, or drinking-glass without its foot, being regular cones adhering by their point or apex to the leaf; and the top or broad part is hollowed a little way, so that it appears like a drinking class with a cover.

CUPANIA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. There are three species, small trees of the West Indies, which possess no remarkable property

CUPEL, a shallow earthen vessel, somewhat resembling a cup, from which it derives its name. It is made of phosphate of lime, or the residue of burned bones rammed into a mould, which gives it its figure. This vessel is used in assays wherein the precious metals are fused with lead, which becomes converted into glass, and carries the impure alloy with it. See ASSAY.

CUPELLATION. The refining of gold by scorification with lead upon the cupel, is called cupellation. See ASSAY.

CUPOLA, in architecture, a spherical

vault; or the round top of the dome of a church, in form of a cup inverted.

CUPPING, in surgery, the operation of applying cupping-glasses for the discharge of blood, and other humours, by the skin.

CUPRESSUS, the cypress-tree, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 51st order, coniferæ. There are seven species; the most remarkable are the following: 1. The sempervirens, or evergreen, with an upright straight stem, closely branching all round, into numerous quadrangular branches, rising in the different varieties from 15 to 40 or 50 feet in height, with small, narrow, erect evergreen leaves. 2. The thyoides, or evergreen American cypress, commonly called white cedar, has an upright stem branching out into numerous two-edged branches, rising 20 or 30 feet high, ornamented with the flat evergreen leaves, imbricated like the arbor vitæ, and small blue cones, the size of juniper-berries. 3. The disticha, or deciduous American cypress, grows 50 or 60 feet high, with small spreading deciduous leaves, arranged distichous, or along two sides of the branches. All these species are raised from seeds, and will sometimes also grow from cuttings; but those raised from seeds prove the handsomest plants.

The wood of the first species is said to resist worms, moths, and putrefaction, and to last many centuries. The same tree has been extolled as a remedy in pulmonic diseases, from its supposed property of meliorating the air by its balsamic exhalations.

CURATELLA, a genus of the digynia order, belonging to the polyandria class of plants, and in the natural method ranking with those the order of which is doubtful.

CIRCULIO, in zoology, a genus of insects belonging to the order of coleoptera.

The larvæ of the curculiones bear a resemblance to oblong soft worms. Some species of them, that are dreaded for the mischief they do in granaries, find means to introduce themselves, while yet small, into grains of corn, and there make their abode. Corn-lofts are often laid waste by these insects, whose numbers are sometimes so great as to devour and destroy all the grain. When the insect is come to its full size, it remains within the grain, and there becomes a chrysalis.

CURCUMA, *turmeric*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. It has four barren stamina, with a fifth fertile. There are three species: 1. The rotunda, with a round root, having a jointed root like that of ginger, but round. The flowers are of a pale yellow colour; and in this country are never succeeded by seeds. 2. The longa has long roots of a deep-yellow colour, which spread under; they are about the thickness of a man's finger. The flowers grow in loose spikes on the top of the footstalks; they are of a yellowish-red colour, and shaped like those of the Indian reed. 3. The pallida, which differs from the others in being an annual plant. These plants grow naturally in India, whence the roots are brought to Europe for use. They are used in dying yellow, and in medicine as a remedy for the jaundice.

CURFEW, in the law Latin of the middle ages, *ignitegium*, or *pyritegium*, and in French *couvre-feu*, was a signal for all persons to extinguish their fires at a certain hour. In those times people generally made their fires in holes dug in the centre of the floor, under an opening formed in the roof; and when the fire was to be extinguished, or when the family went to bed, the whole was shut by a cover of wood or earth. Hence in the dark ages, when all ranks were turbulent, a law was established that the fire should be extinguished at a certain hour in the evening; that the cover should be put over the fire place, and that all the family should retire to rest or at least keep within doors. The signal for this was given by the ringing of a bell, which was therefore called the curfew bell.

CURRANS, or CURRANTS. See RIBES.

CURRANTS, also signify a smaller kind of grapes brought principally from Zante and Cephalonia. They are gathered off the bunches, and laid to dry in the sun, and so put up in large butts.

CURRENT, in hydrography, a stream or flux of water in any direction. In the sea, currents are either natural, occasioned by the diurnal motion of the earth round its axis, or accidental, caused by the waters being driven against promontories, or into gulphs and straits, where wanting room to spread, they are driven back, and thus disturb the ordinary flux of the sea. Dr. Halley makes it highly probable that in the Downs there are under-currents, by which as much water is carried out as is brought in by the upper currents.

CURRYING, the method of preparing leather with oil, tallow, &c. The chief business is to soften and supple cows' and calves' skins, which make the upper-leathers and quarters of shoes, coverings of saddles, coaches, and other articles which must keep out water.

When the skins are brought from the tanner's yard, they are first soaked for some time in common water, and when taken out, are stretched on a smooth wooden horse. The currier scrapes off with a paring-knife all the superfluous flesh, and immerses them again. They are next put on a wet hurdle, and trampled with the heels, till they become soft and pliant, when they are steeped in train oil, and afterwards spread out on large tables, and their ends secured. Tallow and oil are rubbed in with a polished stone. The oil could not be rubbed in, unless the hides were well soaked and wetted through with water; the oil occupying the place of the *extract*, which is evaporated by drying.

The skins are afterwards spread out on large tables, and their ends secured by means of a *pummel*, an instrument consisting of a thick piece of wood, the lower side of which is full of furrows, or teeth, crossing each other. The skins are then folded, squared, and moved in various directions, to render them supple. The skins are now coloured black, white, red, green, &c. which process is performed either on the *flesh* or *grain* side; that on the former, by skinners, and that on the *grain* or *hair* side by curriers. When a skin is to be made

white, it is rubbed with chalk, or white-lead, and afterwards with pumice-stone. But, when a black colour is wanted, the skin must be first oiled and dried, then passed over a puff, dipped in water impregnated with iron, when it is immersed in another water prepared with soot, vinegar, and gum-arabic. Thus it gradually acquires a deep dye, and the operations are repeated till it becomes of a shining black.

CURSITOR, an officer or clerk belonging to the chancery, who makes out original writs; of these there are 24 in number, and to each are allotted several counties.

CURSOR, in mathematical instruments, is any small piece that slides; as the piece in an equinoctial ring-dial that slides to the day of the month. It also signifies a brass point screwed on the beam-compasses, which may be moved along the beam for the striking of circles.

CURTATE *distance*, in astronomy, the distance of a planet from the sun to that point where a perpendicular let fall from the planet meets with the ecliptic.

CURTIN, **Curtain**, or **Courtin**, in fortification, is that part of the rampart of a place which is betwixt the flanks of two bastions bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way and into the moat.

CURTISIA, a genus of the tetrandria monogynia class and order. There is one species, a tree of the Cape.

CURVATURE *of a line*, is the peculiar manner of its bending or flexure, by which it becomes a curve of certain peculiar properties.

Of all the circles that touch a curve in any given point, that is said to have the same curvature with it, which touches it so closely, that no circle can be drawn through the point of contact between them: and this circle is called the circle of curvature; its centre, the centre of curvature; and its semi-diameter, the ray of curvature belonging to the point of contact.

CURVE, in geometry, a line which, running on continually in all directions, may be cut by one right line in more points than one.

Curves, *family of*, according to Wolfius, is a congeries of several curves of different kinds, all defined by the same equation of an indeterminate degree; but differently, according to the diversity of their kinds.

CUSCUTA, *dodder*, a genus of the digynia order, in the tetrandria class of plants, and in the natural method ranking under those the order of which is doubtful. There are four species, one of which is a native of Britain, viz. the Europaea, dodder, hell-weed, or devil's-guts. This is a most singular plant, almost destitute of leaves, parasitical, creeping, fixing itself to whatever is next to it. It decays at the root, and afterwards is nourished by the plant which supports it. Hops, flax, and nettles, are its common support, but principally the common nettle.

CUSSONIA, a genus of the pentandria digynia class and order. There are two species, natives of the Cape.

CUSTOM, a very comprehensive term, denoting the manners, ceremonies, and fashions of a people which, having turned into a habit, and passed into use, obtains the force of laws; in which sense it implies such usages as, though voluntary at first, are yet, by practice, become necessary.

Custom is hence, both by lawyers and civilians, defined *lex non scripta*, a law, or right, not written, established by long usage, and the consent of our ancestors: in which sense it stands opposed to the *lex scripta*, or the written law.

CUSTOS, the principal clerk belonging to the court of common pleas, whose business it is to receive and keep all the writs made returnable in that court, filing every return by itself; and, at the end of each term, to receive of the prothonotaries all the records of the nisi prius, called the posteas.

Custos *rotulorum*, an officer who has the custody of the rolls and records of the sessions of peace, and also of the commission of the peace itself. He usually is some person of quality, and always a justice of the peace, of the quorum, in the county where he is appointed.

CUT-*water*, or knee of the head, the sharpness of the head of the ship, below the beak; so called because it cuts or divides the water before it comes to the bow.

CUTICLE, *cuticula*, in anatomy, a thin membrane closely lying upon the skin, or cutis, of which it seems a part, and to which it adheres very firmly, by the intervention of the corpus reticulare.

CUTIS, the skin, in anatomy, is that strong thick covering which envelopes the whole external surface of animals. It is composed chiefly of two parts: a thin white elastic layer on the outside, which is called the epidermis, or cuticle; and a much thicker layer, composed of a great many fibres, closely interwoven, and disposed in different directions; this is called the cutis, or true skin.

CUTTING, in heraldry, is used for the dividing a shield into two equal parts, from right to left, parallel to the horizon, or in the fesse way.

CYANELLA, a genus of the hexandria monogynia class and order. There are three species, natives of Africa.

CYANILE, a stone commonly found in granite rocks. The primitive form of its crystals is a four-sided oblique prism, the sides of which are inclined at an angle of 130°. It is sometimes crystallized in six-sided prisms. It causes single refraction, and its specific gravity is from 3.5. to 3.6. Its colour is white, with shades of sky or Prussian blue.

CYCAS, in botany, a genus of plants belonging to the first natural order, palmae. The fruit is a dry plum with a bivalved kernel. There are two species: 1. The circinalis, or sago-tree, grows spontaneously in the East Indies, and particularly on the coast of Malabar. It runs up with a straight trunk to 40 feet or more. The leaves are pinnated, and grow to the length of seven or eight feet. The flowers are produced in long bunches at the footstalks of the leaves, and are succeeded by oval fruit, about the size of large plums, of a red colour when ripe, and a sweet flavour. Each contains a hard brown nut, inclosing a white meat, which tastes like a chesnut.

This is a valuable tree to the inhabitants of

India, as it not only furnishes a considerable part of their constant bread, but also supplies them with a great article of trade. The Indians saw the body into small pieces, and after beating them in a mortar, pour water upon the mass; this is left for some hours to settle. When fit, it is strained through a cloth; and the finer particles of the mealy substance running through with the water, the gross ones are left behind and thrown away. After the farinaceous part has sufficiently subsided, the water is poured off, and the meal being properly dried, is occasionally made into cakes and baked.

The same meal more finely pulverized, and reduced into granules, is what is called sago, which is sent into all parts of Europe, and sold in the shops as a great strengthener and restorative.

2. The cycas revoluta, or bread-tree of the Hottentots, was discovered by Professor Thunberg. The pith, or medulla, is collected and tied up in skins, and then buried in the earth for several weeks, till it becomes sufficiently mellow and tender to be kneaded up with water into a paste, of which they afterwards make small loaves or cakes, and bake them under the ashes.

CYCLAMEN, *sowbread*, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 21st order, preciæ. There are five species, which produce many beautiful varieties. They are low, herbaceous, flowery perennials, of the tuberous-rooted kind, with numerous angular, heart-shaped, spotted, marbled leaves, with flowers, of various colours. All the varieties are extremely ornamented, and some of the flowers very fragrant.

CYCLAS, a genus of the decandria monogynia class and order. There are two species, trees of Guiana.

CYCLE, in chronology, a certain period or series of years, which regularly proceed from the first to the last, and then return again to the first, and circulate perpetually. The most considerable cycles are those of the sun, of the moon, and of the Roman indiction.

CYCLOID. The cycloid is a curve generated by the motion of any point in the periphery of a circle, whilst the periphery itself revolves on a right line, till that point which touched the line at the beginning of the motion be brought to touch it again.

CYCLOPÆDIA, or *Encyclopædia*, denotes the circle or compass of arts and sciences.

CYCLOPTERUS, the sucker, in ichthyology, a genus belonging to the order of amphibia nantes. There are three species:

1. The lumpus, or lump-fish, grows to the length of nineteen inches, and weighs seven pounds. The shape of the body is like that of the bream, deep and very thick, and it swims edge-ways. The back is sharp and elevated; the belly flat, of a bright crimson colour. Along the body are several sharp bony tubercles. Beneath the pectoral fins is an aperture surrounded with a fleshy substance, edged with small threads, by which the animal adheres so closely to the substance it fastens on, as not to be removed but with great trouble. These fish abound in the Greenland seas, and on the coast of Scotland. 2. The liparis, or sea snail, is of a soft unctuous texture, and soon melts away. The length is five inches, and the colour a pale brown. 3. Cyclopterus minor, or the lesser sucking fish, is found on the coast of Britain. It is about four inches, and fastens very tenaciously to stones and rocks.

CYDER. See Cider.

CYGNUS, in astronomy, a constellation of the northern hemisphere, consisting of 17 stars according to Ptolemy's Catalogue; of 19 in Tycho's; and in the Britannic Catalogue of 107.

CYLINDER, in geometry, a solid body, supposed to be generated by the rotation of a parallelogram. See Geometry.

Cylinder, *properties of the.* 1. The section of every cylinder by a plane oblique to its base is an ellipsis. 2. The superficies of a right cylinder is equal to the periphery of the base multiplied into the length of its side. 3. The solidity of a cylinder is equal to the area of its base multiplied into its altitude. 4. Cylinders of the same base, and standing between the same parallels, are equal. 5. Every cylinder is to a spheroid inscribed in it as 3 to 2. 6. If the altitudes of two right cylinders be equal to the diameters of their bases, those cylinders are to one another as the cubes of the diameters of their bases.

CYLISTA, a genus of the class and order diadelphia decandria. There is one species.

CYMATIUM, in architecture, a member or moulding of the cornice, the profile of which is waved, that is, concave at the top, and convex at the bottom.

CYMBACHNE, a genus of the class and order polygamia monœcia. The inflorescence is half-spiked. There is one species, a grass of Bengal.

CYMBAL, or *cymbalum*, a musical instrument of antiquity, similar to the tympanum or drum. The cymbal was round, and made of brass, like our kettle-drums; but is generally thought to have been smaller.

CYMBARIA, a genus of the class and order didynamia angiospermia. The calyx is ten-toothed; capsule cardate, two-celled. There is one species, an herbaceous plant of the mountains of Dauria.

CYMOPHANE, the oriental chrysolite of jewellers. This stone has been found only in Brazil, the island of Ceylon, and at Northschink in Siberia. It is usually met with in round masses about the size of a pea, but it is sometimes crystallized.

CYNANCHUM, *bastard dog's-bane* a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 30th order, contortæ. There are 27 species, of which the following are the most remarkable:

1. The acutum, or Montpelier scammony.

2. The Monspeliacum, or round-leaved Montpelier scammony. They abound with a milky juice like the spurge which, when concreted, has frequently been sold for scammony.

CYNARA, the *artichoke*, a genus of the polygamia æqualis order, in the syngenesia class of plants. Of this genus there are six species, but only two are cultivated for use.

1. The scolymus, or garden artichoke, has large, thick, perennial roots, crowned by a cluster of large, pinnatifid, erect leaves. In

the middle are upright stalks rising a yard high, on the top of which is a large round scaly head, composed of numerous, oval, calycinal scales, inclosing the florets, sitting on a broad fleshy receptacle, which, with the fleshy base of the scales is the only eatable part of the plant. The varieties of this species are, 1. The conical green-headed French artichoke, having the small leaves terminated by spines, the head of a light-green colour, with the scales pointed at top, opening, and turning outward. 2. The globular-headed Dutch artichoke, having leaves without spines, a strong stalk, the head large, globular, a little compressed at top, and of a brown colour; broad obtuse scales emarginated at top, growing close, and turning inward.

2. The cardunculus, or cardoon, greatly resembles the artichoke, but is of larger and more regular growth; the leaves being more upright, taller, broader, and more regularly divided; and the stalks of the leaves blanched are the only eatable parts of the plant.

CYNICS, a sect of ancient philosophers, who valued themselves upon their contempt of riches and state, arts and sciences, and every thing, in short, except virtue or morality.

CYNIPS, in zoology, a genus of insects belonging to the hymenoptera order. The quercus folii, or oak-leafed cynips, is of a shining brown colour. It is in the little, smooth, round, hard galls, found under the oak-leaves, generally fastened to the fibres, that this insect is produced, a single one in each gall.

The quercus gemmæ, or oak-bud cynips, is of a very dark green, slightly gilded. It deposits its eggs in oak-buds, and produces one of the finest galls. There are 19 species of this insect.

CYNOGLOSSUM, hound's-tongue; a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 41st order, asperifoliæ. There are 12 species, none of them remarkable for their beauty. The root of one of them, the officinale. was formerly, used in medicine, but it is now discarded from practice.

CYNOMETRA, a genus of the monogynia order in the decandria class of plants; and in the natural method ranking with those of which the order is doubtful. There are two species.

CYNOMORIUM, a genus of the monandria order, in the monœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. There are three species, of no note.

CYNOSORUS, a genus of the digynia order, belonging to the triandria class of plants, and in the natural method ranking under the 4th order, gramina. There are 20 species, four of which are natives of Britain, viz. the cristatus, or crested dog-tail grass; the echinatus, or rough dog-tail grass: the cæruleus, or blue dog-tail grass; and the paniceus, or bearded dog-tail grass.

CYPERUS, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 3d order, calamariæ. There are 53 species; the only remarkable are the round, the long sweet cyperus, and the papyrus. The former is a native of the East Indies, and grows by the sides of rivulets, ditches, &c.

2. The long-leaved, commonly called English or Flemish cyperus, grows in the water, and along the banks and river sides. The roots of both plants are esteemed cordial and diuretic, and the long cyperus is much used by perfumers and glovers.

3. The papyrus is famous both in ancient and modern history, and a very minute description of it is given by Pliny. It grows in the lakes of Ethiopia and Egypt. It was very early in use as paper, Numa having left a number of books written on papyrus. The paper was made from the pellicle between the pith and the bark.

CYPRÆA, or *gowrie*, in zoology, a genus of insects belonging to the order of vermes testacea. It is an animal of the limax or snail kind.

CYPRESS. See CUPRESSUS.

CYPRINUS, in ichthyology, a genus of fishes belonging to the order of abdominales. There are 31 species, principally distinguished by the number of rays in the vent-fin. The most remarkable are:

1. The carpio, or carp. This fish chiefly abounds in the rivers and lakes of Polish Prussia, where they are sometimes taken of a vast size.

Carp are very long lived. Gesner brings an instance of one that was near 100 years old. They grow also to a very great size. Some authors speak of carp weighing 200 pounds, and being five feet in length. The carp is extremely cunning, and on that account is sometimes styled the river-fox. They are also very shy in taking a bait; yet at the spawning-time they are so simple, as to suffer themselves to be caught, by any body that will attempt it.

In some parts carp are fattened by being kept out of water, and fed with bread soaked in milk; but in this case they require to be very frequently dipped in water, over which they are kept suspended in a net, and wrapped in moss.

2. The barbus, or barbel, is an extremely coarse fish. It is so tame as to suffer itself to be taken by the hand; and people have been known to take numbers by diving for them. The barbel is about the length of three feet, and weighs about 18 pounds; the belly white; the dorsal fin is armed with a remarkably strong spine, with which it can inflict a very severe and dangerous wound on the incautious handler, and even do much damage to nets. The roe is very noxious, affecting those who unwarily eat of it, with a nausea, vomiting, purging, and a slight swelling.

3. The tinea, or tench, is reckoned a wholesome and delicious food in this country; but the Germans are of a different opinion. By way of contempt, they call it the shoe-maker. Gesner even says, that it is insipid and unwholesome. The tench is thick, and short in proportion to its length. The colour of the back is dusky; the dorsal and ventral fins of the same colour; the head, sides, and belly, of a greenish cast, most beautifully mixed with gold.

4. The gobio, or gudgeon, is generally found in gentle streams, and is of a small size, the largest not exceeding ½ pound weight.

5. The brama, or bream, is an inhabitant of lakes, or the deep parts of still rivers. It is a fish that is very little esteemed, being extremely insipid.

6. The rutilus, or roach, is a common fish,

found in still deep rivers. It has never been known to exceed five pounds in weight.

7. The leuciscus, or dace, like the roach, is gregarious, haunts the same place, is a great breeder, very lively, and, during summer, is very fond of frolicking near the surface of the water. It never exceeds the weight of a pound and a half.

8. The cephalus, or chub, is a very coarse fish, and full of bones. It frequents the deep holes of rivers, and in summer commonly lies on the surface beneath the shade of some tree or bush. It feeds on worms, caterpillars, grasshoppers, and other insects that happen to fall into the water; and it will even feed on cray-fish. It will rise to a fly. Some of this kind have been known to weigh eight or nine pounds.

9. The alburnus, or bleak. These fish are very common in many of our rivers, and keep together in large shoals. At certain seasons they seem to be in great agonies; they tumble about near the surface of the water, and are incapable of swimming far from the place; but in about two hours they recover and disappear. This is supposed to be in consequence of their being tormented by a species of hair-worm. The bleak seldom exceeds five or six inches in length. Artificial pearls are made with the scales of this fish; and probably also with those of the dace.

10. The auratus, or golden fish, a small fish, domesticated by the Chinese, and generally kept for ornament by great people in their courts and gardens. They breed them in small ponds made for the purpose, in basons, and even in porcelain vessels. This fish is no larger than our pilchard. They were first introduced into England about the year 1691; but were not generally known till 1728.

CYPRIPEDIUM, *lady's slipper,* a genus of the diandria order, in the gynandria class of plants, and in the natural method ranking under the 5th order, orchideæ. There are five species; of which only one, viz. the calceolous, is a native of Britain. It grows in rough ground in different parts of the island. The other species are natives of America.

CYRILLA, a genus of the class and order didynamia angiospermia. There is one species, a handsome plant of the West Indies.

CYRTANTHUS, a genus of the class and order hexandria monogynia. The corolla is tubular, inserted in the tube. There are two species, bulbs of the Cape.

CYTINUS, a genus of the dodecandria order, in the gynandria class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. There is one species.

CYTISUS, *tree trefoil,* a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiated, with the upper lip bifid; inferior tridentate; the legumen attenuated at the base. There are eighteen species. All the cytisuses are shrubs without spines, most of them fit for ornamental plantations. They are hardy; the leaves are ternate, and in some the flowers grow in bunches.

D.

D, One of the letters of the alphabet, the fourth in order, and the third consonant. It is formed in the voice, by applying the top of the tongue to the forepart of the palate, and then separating them with a gentle gust of the breath, the lips being at the same time open,

As a numeral D denotes 500; and with a dash over it, thus D denotes [illegible]000. Used in abbreviation, it has various significations; thus, D. stands for doctor, as M. D. doctor of medicine; D. T. doctor of theology; D. D. signifies doctor of divinity; D. D. D, is used for dat, dicat, dedicat; and D. D. D. D. for dignum deo donum dedit.

DACE, a species of Cyprinus.

DACTYL, in ancient poetry, a metrical foot, consisting of one long and two short syllables, as mūrmŭrĕ. The dactyl and spondee are the only feet or measures used in hexameter verses: the former being esteemed more sprightly, and the latter more solemn and grave.

DAFFODIL, the same with the narcissus of botanists.

DAGGYSA, a genus of the vermes class and molusca order, of which there is only a single species. The dagysa inhabits the Spanish sea, is about three inches long, and one inch thick. They adhere to each other by the sides, and so nearly resemble the genus salpha, that they might, with propriety, be incorporated into one.

DAIS, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. There are three species, natives of India and the Cape.

DALBERGIA, a genus of the decandria order, in the diadelphia class of plants. There are two species, trees of Malabar and Surinam.

DALECHAMPIA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. There are two species, of which the scandens is a native of Jamaica. It is a climbing plant, which rises to a considerable height, and is remarkable for having its leaves armed with bristly hairs, which sting the hands of those who touch them.

DAMAGE, generally signifies any hurt or hindrance that a man receives in his estate; but in the plural in common law, is the recompence that is given to a man by a jury as a satisfaction for some injury sustained.

In actions upon the case, the jury may find less damages than the plaintiff lays in his declaration, though they cannot find more.

DAMAGE *faisant,* is where the beasts of another come upon a man's land, and there feed, tread, or spoil his corn or grass there

growing; in which case the owner of the ground may impound them, till satisfaction be made.

DAMASK, a silk stuff, with a raised pattern of dressed silk, both in warp and woof: they are made at Chalons in Champagne, and in some places in Flanders, as at Tournay, &c.

Damask is also a kind of wrought linen made in Flanders and in this country. It takes its name on account of its resemblance to damasks. It is chiefly used for table linen.

Damask is also applied to a very fine steel, in some parts of the Levant, chiefly at Damascus in Syria; whence its name. It is used for sword and cutlas-blades, and is finely tempered.

DAMASKEENING, or **Damasking**, the art or operation of beautifying iron, steel, &c. by making incisions in them, and filling them up with gold and silver wire; chiefly used for adorning sword-blades, locks of pistols, &c.

DAMASONIUM, a genus of the hexandria class and order. The spathe is one leafed; perianthum one-leafed, three-parted; berry ten-celled, inferior, there is one species, a native of India.

DAMPS. The permanently elastic fluids which are extricated in mines, and are destructive to animal life, are called damps by the miners. The chief distinctions made by the miners are, choak-damp, which extinguishes their candles, hovers about the bottom of the mine, and consists for the most part of carbonic acid gas; and fire-damp, or hydrogen gas, which occupies the superior spaces, and does great mischief by exploding whenever it comes in contact with their lights. See Gas, Combustion, and Lamp.

DANCE, or **Dancing**, as at present practised, may be defined, "an agreeable motion of the body, adjusted by art to the measures or time of instruments, or of the voice."

The practice is of very great antiquity, and from its being so common among the most uncivilized and barbarous nations, it appears to have had its origin in the natural disposition of the mind to express its emotions in corresponding gestures of the body. Like every other popular amusement, dancing has its strenuous advocates: but when we consider that its claims are, at best, but of the negative kind, and how largely it is made to minister to licentiousness, both in our own country, and in others, we feel disposed to adopt the opinion of Dr. Gregory, who, in his Encyclopædia, thus defines it: "Dance, *a silly amusement of the idle and thoughtless.*"

DAPHNE, spurge-laurel, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. There is no calyx; the corolla is quadrifid and withering, inclosing the stamina. The fruit is a monospermous berry. There are 28 species: these are shrubs about five feet high. D. Mezereum. Mezereon is a strong woody plant, putting forth branches on every side, so as to form a regular head. The flowers come out very early in the spring, before the leaves, in clusters all round the shoots of the former year. The leaves are smooth and entire, of a pale green colour, about two inches long and three quarters of an inch broad. It is a native of Lapland, Sweden, Denmark, Germany, Switzerland, France, and Great Britain.

DARAPTI, among logicians, one of the modes of syllogisms of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

Dar- Every body is divisible:
ap- Every body is a substance;
ti. Therefore some substance is divisible.

DASYPUS, the armadillo, in natural history, a genus of mammalia of the order bruta. Generic character: no tusks; grinders short and cylindrical, and seven or eight in each jaw; body covered with a shelly armour, intersected by circles. These animals chiefly inhabit South America, where they burrow like rabbits in the ground, and live principally upon roots and fruits. They exhibit a singular difference from other quadrupeds, in that testaceous substance which covers them completely, and yet is so admirably adapted to their frame by its minute intersections, as by no means to interfere with flexibility or quick movement. When attacked, they roll themselves up into the compactness of a ball; thus presenting to the enemy almost impenetrable armour. They repose by day, and at night quit their habitations for food. They are perfectly inoffensive. In a state of confinement they will devour with considerable appetite animal food, for which, in a state of nature, they do not appear to have any relish. They drink most copiously, and are often found extremely fat. They are regarded as a very great luxury for the table, and are not unfrequently dug from their burrows to be sold for food; for this purpose, however, they should always be taken young.

Their claws are of uncommon size and strength, and enable them to form their subterraneous habitations with extreme facility. Shaw reports, that the female produces three or four times in a year; and Gmelin states, that she produces every month. It is ascertained, therefore, that they are highly prolific. It is the practice of naturalists to define the different species by the different number of testaceous circles on the body. Gmelin enumerates ten species, and Shaw six. This extraordinary variety among quadrupeds deserves the particular attention of naturalists, who do not appear to have so clearly defined the several species, or to have collected so many particulars of the manners and habits of the animal in general as its most singular structure excites a desire to be informed of.

DATA, among mathematicians, a term for such things or quantities as are given or known, in order to find other things that are unknown. Euclid uses the word data for such spaces lines, and angles, as are given in magnitude, or to which we can assign others equal.

DATE, in law, is the description of the day, month, year of our Lord, and year of the reign of the king, in which a deed or other writing is made.

In writings of importance, the date should be written in words at length. An antedate is a date prior to the real time when the instru-

ment was signed. A post date is that which is posterior to the real time when the instrument was passed.

DATE. See PHŒNIX.

DATISCA, a genus of the dodecandria order, in the diœcia class of plants, and in the natural method ranking under the 54th order, miscellaneæ. There are two species, but not remarkable.

DATISI, in logic, a mode of syllogism in the third figure, in which the major is a universal affirmative, and the minor and conclusion particular affirmative propositions.

DATIVE, among grammarians, the third case in the declension of nouns, expressing the relation of a thing to whose profit or loss some other thing is referred. It is called dative, because usually governed by a verb, implying something to be given to some person. In the English language, this relation is expressed by the signs *to* or *for*.

DATURA, the thorn apple, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, luridæ. There are eight species: the most remarkable are,

1. The stramonium, or common thorn-apple, rises about a yard high, with an erect, strong, hollow, green stalk, branching luxuriantly, having the branches widely extended on every side; large, smooth, dark-green leaves; and from the divisions of the branches, large white flowers singly, succeeded by oval, prickly capsules, growing erect, commonly called thorn-apples. At night the upper leaves rise up and inclose the flowers. The blossoms have sometimes a tinge of purple or violet. An ointment prepared from the leaves gives ease in external inflammations and in the hæmorrhoids.

The seeds were recommended by Dr. Stock to be taken internally in cases of madness: but they seem to be a very unsafe remedy. Taken even in a small dose, they bring on a delirium, and in a large one, would certainly prove fatal. Cows, horses, sheep, and goats, refuse this plant.

2. Datura arborea, is a stove-plant, much esteemed for the beauty and fragrance of its large white flowers.

DAUCUS, the carrot, a genus of the digynia order in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. There are seven species, but the only one which merits attention is the carota, or common carrot. This is so well known as to need no description. There are several varieties, as the white, the orange, and the purple carrot; but of these the orange carrot is the most esteemed. It grows longer, larger, and is commonly more handsome, than the others, being often 15 or 18 inches long in the eatable part, and from two to four in diameter at top. Carrots are propagated by seeds; which are sown at different seasons of the year, in order to procure a supply of young roots for the table at all times. The season for sowing for the earliest crop is soon after Christmas; the manner of cultivating them is too well known to need any particular description. A rich sandy loam is the best land for carrots, which after the crop is removed, will be in high cultivation for corn.

DAVIT, in a ship, a long beam of timber, used as a crane to hoist the flukes of the anchor to the top of the bow, without injuring the sides of the ship as it ascends; an operation which by mariners is called fishing the anchor.

DAY, signifies that space of time during which it is light; or it is the time between the rising and setting of the sun.

The word day is often taken in a larger sense, so as to include the night also; or to denote the time of a whole apparent revolution of the sun round the earth, in which sense it is called by some a natural day, and by others an artificial one; but to avoid confusion it is usual to call it in the former sense simply the day, and in the latter anychthemron, which implies both day and night, and is divided into 24 parts, called hours.

Different nations begin their day at a different hour: thus the Egyptians began their day at midnight, and in this they have been followed by most European nations.

The Babylonians began their day at sun-rising, reckoning the hour immediately before its rising again the 24th hour of the day, whence the hours reckoned in this way are called the Babylonic.

DAYS *of grace*, in commerce, are a customary number of days allowed for the payment of a bill of exchange, &c. after the same becomes due. Three days of grace are allowed in England. For other countries their number is regulated according to distance.

DEAD-*men's-eyes*, in the sea-language, a kind of blocks with many holes in them, by which the shrowds are fastened to the chains: the crow-feet reeve also through these holes.

DEAD-*reckoning*, in navigation, the calculation made of a ship's place by means of the compass and log; the first serving to point out the course she sails on, and the other the distance run. From these two things given, the navigator making proper allowances for the variation of the compass, lee-way, currents, &c. is enabled, without any observations of the sun or stars, to ascertain the ship's place tolerably well.

DEAD-*rising*, among sailors, that part of a ship which lies aft, between the keel and the floor-timbers, next to the stern-post.

DEAD *ropes*, on board a ship, such ropes as do not run in any block.

DEAD-*water*, at sea, the eddy-water just astern of a ship, so called because it does not pass away so swiftly as the water running by her sides does.

DEAFNESS, the state of a person who wants the sense of hearing; or, the disease of the ear, which prevents its due reception of sounds. Deafness generally arises either from an obstruction or a compression of the auditory nerve; or from some collection of matter in the cavities of the inner ear; or from the auditory passage being stopped up by some hardened excrement; or, lastly, from some excrescence, a swelling of the glands, or some foreign body introduced within it.

DEAL, a thin kind of fir planks, of great use in carpentry: they are formed by sawing the trunk of a tree into a great many longitudinal divisions, of more or less thickness, according to the purposes they are intended to serve

Deals are rendered much harder by throwing them into salt water as soon as they are sawed, keeping them there three or four days, and afterwards drying them in the air or sun; but neither this nor any other method yet known, will preserve them from shrinking. Deals are imported into this country from Christiana, and other parts of Norway; from Dantzic, and various parts of Prussia; from St. Petersburgh, Archangel, Narva, Memel, &c.

DEAN, an ecclesiastical dignitary in cathedral and collegiate churches, and head of the chapter. As there are two foundations of cathedral churches in England, the old and the new, so each has a separate way of creating deans.

Rural deans are those who have no absolute judicial power in themselves, but who have the ordering of ecclesiastical affairs within their deanery by the direction of the bishop or archdeacon.

DEATH. Death is usually defined to be a total stoppage of the circulation of the blood, and a cessation of the animal and vital functions consequent thereon, such as respiration, sensation, &c.

The body, when deprived of life, undergoes a continual change. Its smallest fibres become rigid; its minutest vessels become solid fibres, no longer pervious to the fluids; its greater vessels grow hard and narrow; and every thing becomes contracted, closed, and bound up; whence the [illegible]ness, immobility, and extenuation observable in extreme old age. By such means the offices of the minuter vessels are destroyed; the humours stagnate, harden, and at length coalesce with the solids. The most subtile fluids of the body are thus intercepted and lost, the concoction weakened, and the reparation prevented; the coarser juices alone continue to run through the greater vessels, to the preservation of life after the animal functions are destroyed. At length, by these changes, death becomes inevitable, as the necessary consequence of life Such is the gradual process of nature; but it is rare indeed that life is thus long protracted: or that death succeeds merely from the decays and impairment of old age; the work, in thousands of instances, is cut short by the ravages of disease.

The signs of death are in many cases extremely uncertain; and this ought to operate as a caution against hasty burials, particularly in cases of sudden death, drowning, &c. Between life and death the shade is often so undistinguishable as to defy the powers of art to determine where the one ends and the other begins. Our first associations with the idea of death are all of the disgustful and alarming kind: and they are collected from all quarters, from the sensible pains of every sort, from the imperfection, weakness, loathsomeness, corruption, and disorder, where disease, old age, death, animal or vegetable, prevail, in opposition to the beauty, order, and lustre of life, youth, and health. Such associations are truly painful, and yet they are eminently suited to guard the heedlessness and inexperience of youth, from hurrying them into danger and destruction; and to lead the mind to set a proper value on the present state of existence as being only introductory to the eternal future.

DEATH-*watch*. A small insect which makes a noise resembling the beat of a watch; the vulgar have long taken this as a presage of death in the family where it is heard; an error which cannot be too frequently confuted by facts. The real cause of the ticking noise of this little insect is now well understood. It is described by Mr. Derham and others, to be the signal by which the male invites the female There are two kinds of the death-watch. One is of a brown colour and spotted, having pellucid wings: the other is grey, and resembles a louse when viewed with the naked eye; it is very shy of beating when disturbed.

DEBENTURE, is a certificate delivered at the custom-house, when the exporter of any goods or merchandize has complied with the regulations prescribed by certain acts of parliament, in consequence of which he is entitled to a bounty or drawback on the exportation.

DEBT, a sum due from one person to another, in consequence of work done, goods delivered, or money or other value, for which reimbursement has not been made. The non-payment in these cases is an injury.

DEBT, *National*. See NATIONAL DEBT.

DECAGON, in geometry, a plane figure with ten sides and ten angles; it is called a regular decagon, when all the sides and angles are equal.

DECANDRIA, in the Linnæan system of botany, a class of plants, the great characteristic of which is, that they have hermaphrodite flowers, with ten stamina in each.

DECIDUOUS, an appellation chiefly used in respect to plants: thus the calyx or cup of a flower is said to be deciduous, when it falls along with the flower-petals; and, on the contrary, it is called permanent, when it remains after they are fallen. Again, deciduous leaves are those which fall in autumn; in contradistinction to evergreens.

DECK of a ship, is a planked floor from stem to stern, upon which the guns lie, and where the men walk to and fro. Great ships have three decks, first, second and third, beginning to count from the lowermost. Half-deck reaches from the mainmast to the stern of the ship. Quarter-deck is that aloft the steerage, reaching to the round-house.

DECLARATION, an exposure in writing, of the grief and complaint of the demandant, or plaintiff, against the defendant or tenant, wherein he is supposed to have done some wrong.

DECLARATION *of war*, a public proclamation made by the herald at arms to the members or subjects of a state, declaring them to be at war with any foreign power, and forbidding all and every one to aid or assist the common enemy at their peril.

DECLENSION, in grammar, an inflection of nouns according to their cases, as nominative, genitive, dative, &c. See GRAMMAR.

DECLINATION. See GLOBES, *Use of.*

DECOCTION. The operation of boiling. This term is likewise used to denote the fluid itself, which has been made to take up certain soluble principles by boiling. Thus we say a decoction of the bark, or other parts of vegetables, of flesh, &c.

DECOMPOSITION is now understood to imply the separation of the component parts or principles of bodies from each other.

The decomposition of bodies forms a very large part of chemical science. It seems probable from the operations we are acquainted with, that it seldom takes place but in consequence of some combination or composition having been effected. It would be difficult to point out an instance of the separation of any of the principles of bodies which has been effected, unless in consequence of some new combination. The only exception seems to consist in those separations which are made by heat, and voltaic electricity.

DECOY, in naval affairs, a stratagem employed by a ship of war to betray a vessel of inferior force into an incautious pursuit, till she has drawn her within the range of her cannon, or what is called within gunshot. It is usually performed by painting the stern and sides in such manner as to disguise the ship, and represent her either much smaller and of inferior force, or as a friend to the hostile vessel, which she endeavours to ensnare, by assuming the emblems and ornaments of the nation to which the stranger is supposed to belong.

The term is also used to denote a certain method of catching wild fowl by means of ducks and dogs, which are trained for the purpose. This is chiefly practised in Lincolnshire.

DECREPITATION. The crackling noise which several salts make when suddenly heated, accompanied by a violent exfoliation of their particles. This phenomenon has been ascribed to the "sudden conversion of the water which they contain into steam." But the very example, sulphate of barytes, to which these words are applied, is the strongest evidence of the falseness of the explanation; for absolutely dry sulphate of barytes decrepitates furiously without any possible formation of steam, or any loss of weight. The same thing holds with regard to common salt, calcareous spars, and sulphate of potash, which contain *no water*. In fact, it is the salts which are anhydrous, or destitute of water, which decrepitate most powerfully; those that contain water generally enter into tranquil liquefaction on being heated. Salts decrepitate, for the same reason that glass, quartz, and cast-iron crack, with an explosive force, when very suddenly heated; namely, from the unequal expansion of the laminæ which compose them, in consequence of their being imperfect conductors of heat. The true cleavage of minerals may often be detected in this way, for they fly asunder at their natural fissures.

DEED, is a written contract sealed and delivered. It must be written before the sealing and delivery, otherwise it is no deed; and after it is once formally executed by the parties, nothing can be added or interlined; and therefore, if a deed is sealed and delivered with a blank left for the sum, which the obligee fills up after sealing and delivery, this will make the deed void.

A deed must be made by parties capable of contracting, and upon a good consideration; and the subject must be legally and formally set out.

DEEP *sea-line*, or *dip sea-line*, in the sea-language, a small line to sound with; some a hundred and fifty fathoms long, with a hollow plummet at the head, and tallow put into it, to bring up stones, gravel, sand, shells, and the like from the bottom, in order to know the differences of the ground; which being entered from time to time in their books, by comparing observations they guess by their soundings, &c. what coasts they are on, though they cannot see land.

DEER. See CERVUS.

DEFAMATION, the offence of speaking slanderous words of another; and where any person circulates any report injurious to the credit or character of another, the party injured may bring an action to recover damages proportioned to the injury he has sustained; but it is incumbent upon the party to prove he sustained an injury, to entitle him to damages.

DEFENCE, in fortification, all sorts of works that cover and defend the opposite posts, as flanks, casemates, parapets, and faussebrays. See FORTIFICATION.

DEFICIENT *numbers*, those whose parts or multiples added together, fall short of the integer whereof they are the parts; such is 8, its parts, 1, 2, 4, making only 7.

DEFILE, in fortification, a straight narrow passage, through which a company of horse or foot can pass only in file, by making a small front, so that the enemy may take an opportunity to stop their march, and to charge them with so much the more advantage, as those in the front and rear cannot reciprocally come to the relief of one another.

DEFINITION, in rhetoric, is [illegible]cribed by Cicero, a short comprehensive explanation.

The special rules for a good definition, are these: 1. A definition must be universal, or adequate, that is, it must agree to all the particular species or individuals that are included under the same idea. 2. It must be proper, and peculiar to the thing defined, and agree to that alone. These two rules being observed will always render a definition reciprocal with the thing defined, that is, the definition may be used in the place of the thing defined: or they may be mutually affirmed concerning each other. 3. A definition should be clear and plain; and it is a general rule concerning the definition both of names and things, that no word should be used in either of them which has any difficulty in it. 4. A definition should be short, so that it must have no tautology in it, nor any words superfluous. 5. Neither the thing defined, nor a mere synonymous name should make any part of the definition

DEGLUTITION, in medicine, the act of swallowing the food: performed by means of the tongue driving the aliment into the œsophagus, which, by the contraction of the sphincter, protrudes the contents downwards.

DEGRADED *cross*, in heraldry, a cross divided into steps at each end, diminishing as they ascend towards the centre, called by the French peronnee.

DEGREE, in geometry, a division of a circle, including a three hundred and sixtieth part of its circumference.

Every circle is supposed to be divided into three hundred and sixty parts, called degrees, and each degree divided into sixty other parts, called minutes; each of these minutes being again divided into sixty seconds, each second into thirds, and each third into fourths, and so on. See GEOGRAPHY, MAP, SURVEYING.

DELEGATES, *court of*, is so called, be-

cause the judges thereof are delegated by the King's commission under the great seal, to hear and determine appeals in the three following cases: 1. Where a sentence is given in any ecclesiastical cause by the archbishop or his official. 2. When any sentence is given in any ecclesiastical cause in the places exempt. 3. When a sentence is given in the admiral's court, in suits civil and marine, by order of the civil law.

DELFT *ware*, so called because first made at Delft in Holland, is a kind of pottery of baked earth, covered with an enamel or white glazing, which gives it the appearance of porcelain. The basis of this pottery is clay, mixed with a certain quantity of sand; the vessels are slightly baked, so that they resist a sudden application of heat; and they are, lastly, covered with an enamel or glaze, which is composed of common salt, sand ground fine, and the oxides of lead and of tin. The latter gives a white opaque colour to the mass. The furnace and colours used for painting this ware are the same as those employed for porcelain.

DELIMA, in botany, a genus of plants belonging to the polyandria monogynia class, with an elongated style: it has no flower-petals; the cup consists of five leaves; the fruit is a bivalve capsule, and contains two seeds. There is one species.

DELIQUESCENCE. The spontaneous assumption of the fluid state by certain saline substances when left exposed to the air, in consequence of the water they attract from it.

DELIRIUM, in medicine, the production of ideas not answerable to external causes, from an internal indisposition of the brain, attended with a wrong judgment following from these ideas, and an affection of the mind and motion of the body accordingly: and from these increased through various degrees, either alone or joined together, various kinds of deliria are produced.

DELPHINIUM, *dolphin-flower*, or LARKSPUR, a genus of the trigynia order, in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There are 11 species; four are cultivated in gardens. Two of these are annual, and two perennial: they are herbaceous plants of upright growth, rising from 18 inches to four feet in height, garnished with finely divided leaves, and terminated by long spikes of pentapetalous flowers, of blue, red, white, or violet colours. One annual species, the consolida, is found wild in several parts of Britain, and grows in corn-fields.

DELPHINUS, or *dolphin*, a genus of fishes belonging to the order of cete. There are three species:

1. The delphinus, delphis, or dolphin. The natural shape of the dolphin, is almost straight, the back being slightly incurvated, and the body slender; the nose is long, narrow, and pointed, not much unlike the beak of some birds, for which reason the French call it l'oie-de-mer. It has in all 40 teeth, 21 in the upper jaw and 19 in the lower; placed at small distances from each other; so that when the mouth is shut, the teeth of both jaws lock into one another; the spout-hole is placed in the middle of the head; the tail is semilunar; the skin is smooth, the colour of the back and sides dusky, the belly whitish; it swims with great swiftness, and its prey is fish. It was formerly reckoned a great delicacy. This species of dolphin, however, must not be confounded with that to which seamen give the name; the latter being quite another kind of fish, the coryphæna hippuris of Linnæus, and the dorado of the Portuguese.

2. The phocæna, or porpesse. This species is found in all parts of the British seas; but in greatest numbers at the time when fish of passage appear, such as mackarel, herrings, and salmon, which they pursue up the bays with the same eagerness as a dog does a hare. In some places they almost darken the sea, as they rise above water to take breath: porpesses not only seek for prey near the surface, but often descend to the bottom in search of sand-eels and sea-worms, which they root out of the sand with their noses. Their bodies are very thick towards the head, but grow slender towards the tail. The colour of the porpesse is generally black, and the belly whitish; but they sometimes vary. The porpesse is remarkable for the vast quantity of fat that surrounds the body, which yields a great quantity of excellent oil.

3. The orca, or grampus, is found from the length of 15 feet to that of 25. It is remarkably thick, in proportion to its length; one of 18 feet being in the thickest place 10 feet diameter. It is extremely voracious; and will not even spare the porpesse. It is said to be a great enemy to the whale, upon which it will fasten like a dog on a bull, till the animal roars with pain. The nose is flat, and turns up at the end. There are 30 teeth in each jaw. The spout-hole is in the top of the neck. The colour of the back is black, but on each shoulder is a large white spot; the sides marbled with black and white; the belly of a snowy whiteness. These fishes sometimes appear on our coasts, but are found in much greater numbers off the North Cape in Norway.

4. The leucas, a species called by the Germans and Russians "white fish." The body is oblong, and slender, tapering from the back to the tail. It is quite destitute of the dorsal fin. Its length is from 12 to 18 feet. It is common in all the Arctic seas, and forms an article of commerce, being taken on account of its blubber.

DELPHINUS, in astronomy a constellation of the northern hemisphere.

DEMAIN, or DEMESNE, signifies the king's lands appertaining to him in property. No common person has any demains simply understood, for we have no land (that of the crown only excepted) which is not holden of a superior, as all depends either mediately, or immediately, on the crown.

DEMI-*gorge*. See FORTIFICATION.

DEMI-*lune*. See FORTIFICATION.

DEMISE, is applied to an estate in fee simple, fee tail, or for term of life, and so it is commonly taken in many writs. The king's death is in law termed the demise of the king to his successor.

DEMOCRACY, a term derived from Δημος *people*, and κρατειν to *command or govern*, signifies a popular government, in which the supreme power is lodged in the hands of the people; such were Rome and Athens of old; but modern republics, Basil excepted, come nearer to Aristocracy than democracy.

DEMONSTRATION, in logic, a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established.

DEMONSTRATIVE, in grammar, a term given to such pronouns as serve to indicate or point out a thing. Of this number are *hic, hæc, hoc*, among the Latins; and *this, that, these, those*, in English.

DEMURRAGE, is an allowance made to the master of a ship by the merchants, for being detained in port longer than the time appointed and agreed for his departure. The rate of this allowance is generally settled in the charter party.

DEMURRER, is a kind of pause or stop put to the proceeding of an action upon a point of difficulty, which must be determined by the court before any farther proceedings can be had therein.

DENARIUS, in Roman antiquity, the chief silver coin among the Romans, worth in our money about seven pence three farthings. As a weight, it was the seventh part of a Roman ounce.

DENDRITES, or *Arborizations*. This appellation is given to figures of vegetables which are frequently observed in fossil substances. They are of two kinds; the one superficial, the other internal. The first are chiefly found on the surface of stones, and between the strata and in the fissures of those of a calcareous nature.

Several of these dendrites bear a striking resemblance to the poplar; while others exhibit the straight stem, pyramidal form, and pendant branches of the fir. The superficial dendrites are mostly of a brown, changing gradually to a reddish yellow. The internal dendrites are of a deep black. The most esteemed are those found in agates; and more particularly in the sardonyx, cornelian, and other precious stones brought from the East, and which are commonly denominated Moka stones.

DENEB, an Arabic term, signifying tail, used by astronomers to denote several fixed stars. Thus deneb elecet, signifies the bright star in the lion's tail; deneb adigege, that in the swan's tail, &c.

DENDROMETER, from δενδρον *a tree*, and μετρεω *I measure*, an instrument invented by Messrs. Duncombe and Whittel, for which they obtained a patent, so called from its use in measuring trees. It consists of a semicircle divided into two quadrants, and graduated from the middle; upon the diameter there hangs a plummet for fixing the instrument in a vertical position.

The principal use of this instrument is for measuring the length and diameter of any tree, perpendicular or oblique to an horizontal plane, or in any situation of the plane on which it rests, or of any figure, whether regular or irregular, and also the length and diameter of the boughs, by mere inspection; and the inventors of it have calculated tables, annexed to their account of the instrument itself, by the help of which the quantity of timber in a tree is obtained without calculation, or the use of the sliding rule.

The dendrometer, fitted to a theodolite, may be applied to measuring the heights and distances of objects, accessible or inaccessible, whether situated in planes parallel or oblique to the plane in which the instrument is placed. It may be also used for taking all angles, whether vertical, horizontal, or oblique, in any position of the planes in which they are formed.

DENOMINATOR, in arithmetic, a term used in speaking of fractions. The denominator of a fraction is the number below the line, shewing into how many parts the integer is supposed to be divided. Thus in the fraction $\frac{3}{4}$, the number 4 shews that the integer is divided into four parts. So in the fraction $\frac{a}{b}$, b is the denominator.

DENOMINATOR *of a ratio*, is the quotient arising from the division of the antecedent by the consequent. Thus 8 is the denominator of the ratio 40 : 5, because 40 divided by 5 gives 8 for a quotient. It is also called the exponent of a ratio.

DENSITY *of bodies*, is that property directly opposite to rarity, whereby they contain such a quantity of matter under such a bulk. Accordingly, a body is said to have double or triple the density of another body, when their bulk being equal, the quantity of matter in the one is double or triple the quantity of matter in the other. See GRAVITY.

DENSITY *of the planets*. In homogeneous, unequal, spherical bodies, the gravities on their surfaces are as their diameters when the densities are equal, or the gravities are as the densities when the bulks are equal; therefore, in spheres of unequal magnitude and density, the gravity is in the compound ratio of the diameters and densities, or the densities are as the gravities divided by the diameters. See the Tabular View of the Solar System at the end of the article ASTRONOMY.

DENTALIUM, in natural history a genus of the vermes testacea order. The shell has no hinge, and is formed only of one piece. There are eight species. The name dentalium has been given to this shell, from the great resemblance it has to the dentes canini of quadrupeds.

DENTARIA, *toothwort*, or *tooth-violet*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order siliquosæ. There are four species, hardy perennials; producing annual stalks 12 or 18 inches high, adorned with many-lobed leaves, and spikes of flowers of a red or purple colour.

DENTELLA, a genus of the monogynia order, in the pentandria class of plants. The calyx is a five-parted perianthium, with small subulated leaves; the stamina five short subulated filaments; the antheræ small; the pericarpium a globular bilocular capsule; the seeds egg-shaped, and very numerous. There is one species, a native of New Caledonia.

DEODAND, is where any moveable thing inanimate, or beast animate, moves or causes the death of any human being, by mischance.

DEPARTURE, in navigation, is the easting or westing of a ship in respect of the meridian it departed or sailed from; or it is the difference of longitude, either east or west, between the present meridian the ship is under, and that where the last reckoning or observation was made. This departure, any where but under the equator, must be counted according to the

number of miles in a degree proper to the parallel the ship is under. See NAVIGATION.

DEPOT, any particular place in which military stores are deposited for the use of an army. In a more extensive sense, it means several magazines collected together for that purpose. It also signifies an appropriated fort, or place, for the reception of recruits, or detached parties, belonging to different regiments. The barracks near Maidstone are depots for the British cavalry, and Chatham is allotted to the infantry.

DEPRESSION of the *pole*. In sailing or travelling towards the equator a person is said to depress the pole: because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This arises from the spherical figure of the earth. When a star is under the horizon, it is termed the depression of that star under the horizon. The altitude or depression of a star is an arch of the vertical intercepted between the horizon and the star.

DEPRESSION, or DIP OF THE VISIBLE HORIZON, denotes its sinking or dipping below the true horizontal plane, by the observer's eye being raised above the surface of the sea; in consequence of which the observed altitude of an object is by so much too great.

The following table shews the depression or dip of the horizon of the sea for different heights of the eye.

Height of the eye.	Dip of the horizon.	Height of the eye.	Dip of the horizon.	Height of the eye.	Dip of the horizon.
Feet.	″	Feet.	′ ″	Feet.	′ ″
1	0 57	13	3 26	26	4 52
2	1 21	14	3 34	28	5 3
3	1 39	15	3 42	30	5 14
4	1 55	16	3 49	35	5 39
5	2 8	17	3 56	40	6 2
6	2 20	18	4 3	45	6 24
7	2 31	19	4 10	50	6 44
8	2 42	20	4 16	60	7 23
9	2 52	21	4 22	70	7 59
10	3 1	22	4 28	80	8 32
11	3 10	23	4 34	90	9 3
12	3 18	24	4 40	100	9 33

DERMESTES, a genus of coleopterous insects. There are thirty species of which the principal are:

1. The lardarius of an oblong form, and a dim-black colour, easily distinguishable by a light brown stripe, that runs transversely almost the anterior half of the elytra. Its larva is oblong, and destroys preparations of animals preserved in collections, and even feeds upon the insects.

2. The domesticus varies in size and colour, some being found of a dark-brown, others lighter. This insect makes in wooden furniture those little round holes that reduce it to powder.

3. The violaceus is a beautiful little insect; its elytra being of a violet-blue colour, and the thorax covered with green hairs; the legs are black. The larva, as well as the perfect insect inhabits the bodies of dead animals.

4. The fumatus is of a light brown colour, except the eyes, which are black. The thorax is margined, and the insect has the whole carriage of a scarabæus.

5. The ferrugineus is the largest of the genus; its colour is a rusty iron, having many black spots upon the elytra, which give the insect a gloomy appearance.

DESCENT, in general, is the tendency of a body from a higher to a lower place; thus all bodies, unless otherwise determined by a force superior to their gravity, descend towards the centre of the earth. See GRAVITY and MECHANICS.

DESCENT, *line of swiftest*, is that which a body, falling by the action of gravity, describes in the shortest time possible, from one given point to another. And this line, it is proved by philosophers, is the arch of a cycloid, when the one point is not perpendicularly over the other.

DESCENT, in law, or hereditary succession, is the title by which a man on the death of his ancestor acquires his estate by right of representation as his heir at law; and an estate so descending to the heir is in law called the inheritance.

DESERTER, in a military sense, a soldier who, by running away from his regiment or company, abandons the service.

A deserter is, by the articles of war, punishable by death, and, after conviction, is hanged at the head of the regiment he formerly belonged to, with his crime written on his breast, and suffered to hang till the army leave that camp, for a terror to others.

DESACHE', in heraldry, is where a beast has its limbs separated from its body, so that they still remain on the escutcheon, with only a small separation from their natural places.

DESIGN, in a general sense, the plan order, representation or construction of a building, book, painting, &c.

In building, the term ichnography may be used, when by design is only meant the plan of a building, or a flat figure drawn on paper: when some side, or face of the building is raised from the ground, we may use the term orthography; and when both front and sides are seen, in perspective, it may be termed scenography.

DESIGN, in manufactories, expresses the figures with which the workman enriches his stuff, or silk, and which he copies after some painter, or eminent draughtsman, as in diaper, damask, flowered silk, tapestry, and the like.

In undertaking of such kinds of figured stuffs, it is necessary, that before the first stroke of the shuttle, the whole design be represented on the threads of the warp; we do not mean in colours, but with a number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle, for woof. This method of preparing the work is called reading the design and reading the figure, which is performed in the following manner: A paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented on it. This they divide lengthwise, by as many black lines as there are intended threads in the warp; and cross these lines, by others drawn breadthwise, which, with the former, make little equal squares; on the paper thus squared, the

draughtsman designs his figures, and heightens them with colours as he sees fit.

Design is also used in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large. See **Painting.**

DESIGNING, the art of delineating or drawing the appearance of natural objects, by lines on a plane.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scour the country.

DETENTS, in clock-work, are those stops, which, by being lifted up or let down, lock or unlock the clock in striking. See **Horology.**

Detent *wheel*, or **Hoop** *wheel*, in a clock, that wheel which has a hoop almost round it, wherein there is a vacancy at which the clock locks.

DETERGENTS, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade, and carry along with them, such particles as they lay hold on in their passage.

DETERMINATE *problem*, in geometry, that which has but one, or at least, a limited number of answers: as the following problem, which has but one solution, viz. To describe an isosceles triangle on a given line, whose angles at the base shall be double that at the vertex. But the following has two solutions, viz. To find an isosceles triangle, whose area and perimeter are given.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination; such are the explosions of gunpowder, of fulminating silver, gold, &c.

DEVOTION. Devotion is a sincere and ardent worship of the Deity. In order to its being acceptable to the Deity, devotion must be accompanied with the most profound humility: equally removed from the gloom of superstition, the narrowness of bigotry and the vulgar rant of enthusiasm. It must have God for its sole subject, and spring from a sense of entire dependence on him, and of indissoluble obligations to him.

DEW. The moisture insensibly deposited from the atmosphere on the surface of the earth. This interesting, and, till very lately, inexplicable natural phenomenon will be found described under the article Meteorology, to which it properly belongs.

DEXTER, in heraldry, an appellation given to whatever belongs to the right side of the shield, or coat of arms: thus we say, bend-dexter, dexter-point, &c.

DIABETES, in physic, an excessive discharge of urine, which comes away crude, and exceeds the quantity of liquids drunk.

DIADELPHIA, in the Linnæan system of botany, a class of plants the seven[illegible]nth in order. See **Botany.**

DIADEM, in antiquity, a head-band, or fillet, worn by kings, as a badge of their royalty. It was made of silk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck.

Diadem, in heraldry, is applied to certain circles or rims, serving to inclose the crowns of sovereigns and to bear the globe and cross, of the flower-de-luces for their crest.

DIÆRESIS, in grammar, the division of one syllable into two, which is usually noted by two points over a letter, as aulaï instead of aulæ, dissolüenda for dissolvenda.

DIAGONAL, in geometry, a right line drawn across a quadrilateral figure, from one angle to another, by some called the diameter. It is demonstrable, 1. that every diagonal divides a parallelogram into two equal parts. 2. That two diagonals, drawn in any parallelogram bisect each other. 3. A line passing through the middle point of the diagonal of a parallelogram, divides the figure into two equal parts. 4. That the diagonal of a square is incommensurable with one of its sides. 5. That the sum of the squares of the diagonals of every parallelogram, is equal to the sum of the squares of the four sides.

DIAGRAM, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c.

Diagram, among musicians, (from the Greek, the name given by the ancients to the table, or model, representing all the sounds of their system.

DIAL. Dials are of various constructions, some being horizontal, others vertical, and others moveable, so as to apply to any particular latitude at pleasure. The use of a dial is to indicate the hour, which is done by means of a wire, or by a triangular board, &c. placed at right angles to the face or index. This triangular piece is called the stile, or gnomon, and is made to point due north: it should be perfectly vertical, and the dial's face, on which the hours are marked, should be equally divided thereby; the line of 12 being in a true direction with the stile. This line of direction is called the substile; the angle contained between the summit of the stile, and the face of the dial is called the elevation. All which have their planes, or faces parallel with the horizon, are called horizontal dials; those which have perpendicular planes, or faces, are called vertical dials; and such as are neither vertical, nor horizontal, are called reclining dials. When erect dials do not face either the north, or the south, they are called declining dials. A universal dial is one that answers for all latitudes.

The line passing under the centre of the stile longitudinally, and marking the hour of 12, is called the meridian; in declining dials the substile makes an angle with the meridian, in proportion to the deviation from a northerly direction: this angle is the difference of longitude. With respect to the manner of constructing, and of placing these useful instruments, we shall now proceed to give some account.

The following is the most simple dial that can be made. (Fig. 1. Plate X.) Divide a circle into twenty-four equal parts, and draw through the several points of division, rays from the centre. That point which is to be the

north, is to be marked XII., the next on the right XI., and thus as far as V., or IIII.: those on the left of the southern point 12, are to be I., II., III., &c. in regular order down to VIII. In the centre, whence the circle was drawn, fix a pin, equal in length to about a diameter of the circle, and be very careful that it be perfectly upright. Now, placing the dial at such an elevation as may equal the latitude of the place where it is to be used, see that the XIIth hour be on the meridional line. Thus for the latitude of 50, the northerly part XII. would require to be raised 50 degrees from the horizon, so that the face of the dial would stand in the plane of the equator, and cause the shadow of the pin to fall on the index, thus to point out the time of day. This is called the equinoctial dial.

Dialing is frequently performed by the aid of the terrestrial globe; but it is to be observed, that this method is, at best, only an approximation towards accuracy; since globes are seldom constructed with such care as to have all their parts in perfect correspondence with each other; nor are the divisions on the horizon sufficiently minute to give the exact points through which the hour lines are to be drawn. We shall here, however, insert one example, although the practice is by no means recommended.

To construct a horizontal dial by means of a terrestrial globe.

Elevate the pole to the latitude, and turn the globe till any particular meridian, (suppose the first) comes to the north point of the horizon, and the opposite meridian, will cut the horizon in the south. Then, set the hour-index to the uppermost XII on its circle; turn the globe westward till 15 degrees of the equator pass under the brazen meridian, and then the hour index will be at I; and the first meridian will cut the horizon in the number of degrees from the north point, that I is distant from XII. Turn on till fifteen more degrees of the equator pass under the meridian, and the hour-index will be at II. and the first meridian will cut the horizon in the number of degrees that II is distant from XII: and so, by making fifteen degrees of the equator pass under the brazen meridian for every hour, the first meridian of the globe will cut the horizon in the distances of all the hours from XII to VI, or 90 degrees; and then you need go no farther; for the distances of XI, X. IX, VIII, VII, and VI, in the forenoon, are the same from XII, as the distances of I, II, III, IV, V, and VI, in the afternoon:

Thus to make an horizontal dial for the latitude of London, which is about 51 d. 30m. north, elevate the north pole of the globe 51 degrees and a half above the north point of the horizon, and then turn the globe until the first meridian (which is that of London on the English terrestrial globe) cuts the north point of the horizon, and set the hour-index to XII at noon.

Then, turning the globe westward till the index points successively to I, II, III, IV, V, and VI, in the afternoon; or until 15, 30, 45, 60, 75, and 90 degrees of the equator pass under the brazen meridian, you will find that the first meridian of the globe cuts the horizon in the following numbers of degrees from the north towards the east, viz. 11 two thirds, 24 and a quarter 38 one twelfth, 53 and a half, 71 one fifteenth, and 90: the distances of the above hours from XII on the plane of the horizon.

To transfer these, and the rest of the hours, to a horizontal plane, draw the parallel right lines *ac* and *bd* (fig. 2) upon that plane, as far from each other as is equal to the thickness of the gnomon, and the space included between them will be the meridian or twelve-o'clock line on the dial. Cross this meridian at right angles with the six o'clock line *gh*, and setting one foot of your compasses in the intersection *a*, as a centre, describe the quadrant *ge* with any convenient radius or opening of the compasses then setting one foot in the intersection *b* as a centre with the same radius describe the quadrant *fh*, and divide each quadrant into ninety equal parts or degrees.

Because the hour lines are less distant from each other about noon, than in any other part of the dial, it is best to have the centres of these quadrants at a little distance from the centre of the dial-plane, on the side opposite to XII, in order to enlarge the hour-distances thereabout under the same angles on the, plane. Thus, the centre of the plane is at C but the centres of the quadrant are at *a* and *b*.

Lay a ruler over the point *b*; and keeping it there for the centre of all the afternoon hours in the quadrant *fh*; draw the hour-line of 1, through 11 degrees and two-thirds in the quadrant; the hour line of II, through 24 degrees and a quarter, &c. and because the sun rises about four in the morning on the longest days in London, continue the hour-lines of IV, and V, in the afternoon, through the centre *b* to the opposite side of the dial. This done, lay the ruler to the centre *a* of the quadrant *eg*, and through the like divisions or degrees of that quadrant, draw the forenoon hour-lines of XI, X, IX, VIII, and VII; and because the sun sets not before eight in the evening on the longest days, continue the hour-lines of VII and VIII in the forenoon, through the centre *a* to VII and VIII in the afternoon; and all the hour-lines will be finished on this dial.

Lastly, through 51 degrees and a half of either quadrant, and from its centre, draw the right line *ag* for the axis of the gnomon *agi*, and from *g*, let fall the perpendicular *gi*, upon the meridian line *ai*, and there will be a triangle, whose sides are *ag*, *gi*, and *ia*. If a plate similar to this be made as thick as the distance between the lines *ac* and *bd*, and set upright between them, touching at *a* and *b*; its hypothenuse *ag* will be parallel to the axis of the world, when the dial is truly set, and will cast a shadow on the hour of the day.

The trouble of dividing the two quadrants may be saved, by means of a scale with a line of chords upon it: for if we extend the compasses from 0 to 60 degrees of the line of chords; and with that extent, as a radius, describe the two quadrants upon their respective centres, the above distances may be taken with the compasses upon the line, and set off upon the quadrants.

To make an erect dial directly south.

Fig. 3. On the meridionial line *ab*, as it points downwards from the foot, or lowest part of the gnomon, measure off any distance as *ac*, for the size of the dial: at *c* erect the perpendicular *cd*, and make the angle *cad* equal to the elevation of the equator; then make a second

triangle *cde*, the angle at *d* being equal to that at *a*. Through *e* draw *gh* at right angles with *ae*. Carry on *eb* equal to *ed*, and with that distance as a radius, describe the quadrant *ef* from *b* as a centre. Measure off the proper angles from the point *b*, through the several parts of the quadrant, which is divided off into six equal parts; these will fall upon the prolonged line *gh*, and give the points thereon, through which lines being drawn from the centre *a* of the six o'clock line to the hour frame, the places of the several hours will be given. The gnomon is fixed at *a*, equal in length to *cd*, but perpendicular to the face of the dial; some use large angular rods of iron. This kind of dial is often seen on the south sides of country church steeples.

To make an erect dial facing the north, invert the whole of that just described, making the gnomon point upwards instead of downwards, and causing all the lower points to be transferred from left to right, and from right to left. This kind of dial will show the hours before VI. A.M., and after VI. P.M. When such is wanted, the best way is to set up a stout post, with the planes of two dials back to back, they pointing due south and due north, respectively; thus as the pin retires from one, it will set upon the other.

We shall now instruct the reader how to make those scales, which are indispensable towards the attainment of perfection in this pleasing branch of study.

The lines useful in dialing are, 1. a line of chords; 2. a line of latitudes; 3. a line of sines; and 4. a line of hours. They are all derived from the quadrant of a circle, as will be shewn in fig. 4.

Describe a circle and divide it into four equal parts by the lines A B and C D, intersecting in the centre E. Draw the chords A C, C B, B D. Now divide the two segments, or quadrants, A D and C B, each into nine equal parts; either of which contains 10 degrees. Placing one leg of your compasses at B for a centre, draw the several arcs from the quadrant subtended by the chord C B, so that they may fall upon that chord, which being numbered according as the several arcs correspond with the division on the quadrant, will give a line of chords gradually diminishing from B towards C: all the intermediate degrees, or the measures of 10° each, thus obtained, may be removed in the same manner from the quadrant, if it be graduated accordingly.

It will be proper to observe in this place that the chord of 60° is the radius of a circle, whose quadrant is subtended by 90° of the same scale: hence a line of chords is easily made upon any circle, so that any part of that circle may be cut off at pleasure.. This is essential in every branch of mathematics; but in dialing it is indispensable to be known: the reader will have observed, that in forming the horizontal dial, the hour lines are drawn through particular points, so as to make the required angles As he may be at a loss how to effect this on many occasions, we shall give an example in fig. 5, whereby every doubt, or difficulty will be removed.

Let it be required to cut off an angle of 40 degrees from the quadrant, which appertains to a circle for which we have not a line of chords in readiness. On the base line A B measure 60 degrees from any line of chords you may have at hand: it may either exceed, or be less than your base line; we will suppose the former; in this case the base line must be prolonged to the measurement of 60° from your scale, which will carry it on to C. With that 60°, as a radius, and from A, as a centre, describe the quadrant C D, concentric with the quadrant E B, from which you would cut off 40°. Now measure 40 degrees on your line of chords, and, placing one foot of the compasses at C, carry the measurement to F, which will cause the angle F A C to measure 40°, and the line F A will, at C, cut off 40 degrees from the quadrant E B. For an angle does not vary by prolongation; therefore, if the exterior quadrant is cut at 40°, the interior quadrant, being concentric therewith, must correspond with that division.

We now proceed to the opposite quadrant, which is not subtended by a chord, but is divided into nine equal parts, of ten degrees each. Draw from the several points of division on the quadrant eight lines, all parallel with E A, and falling on the radius E D; this gives a line of sines; which is of very extensive use in various branches of mathematics. From A draw eight lines, passing through the several points ascertained on the line of sines, to the quadrant B D: these will cut the chord subtending that quadrant, and give thereon a line of latitudes, of equal length with the line of chords, but very differently divided.

The remaining quadrant C A is to be divided into six equal parts, viz. of 15° each: make the chord C F A, and draw its parallel tangent G H. Through the several points of division on the quadrant, draw lines from the centre E to the line G H, which will then represent a line of hours: one of the extremes will be XII, the other will be VI; the several intermediate places of I, II, III, IV, and V, being ascertained by the various lines proceeding from E.

The 6th figure shews part of a dial, constructed by means of the lines of latitudes and of hours. Having set off the parallels for the substile, and drawn the line of VI o'clock, set off the latitude of your place from A towards B; taking the measurement from the line of latitudes. Then measure the whole extent of your line of hours, and, placing one leg of your compasses at B, let the other fall wherever it may reach on the line C A. Divide the line B C according to the measures on your line of hours; and from A draw lines through the points of division to the hour circle, which will thus be truly intersected at the horal points. We have before stated, that by dividing the quadrant C A. in fig. 4. more minutely, that is, by dividing each of the six portions into four, the halves and quarters of hours may be shewn.

Having already shewn the modes of constructing those dials which are in ordinary use, we must refer the more curious reader to Ferguson's Lectures for a great variety of dials, which could not be introduced into this work without greatly augmenting the volume. He will there find the modes of constructing dials by logarithms, and by trigonometry; together with many items relating to the more abstruse parts of our subject. We shall briefly add, that the following general principle

governs the formation of all dials. Take the words of that great luminary of mechanics, the late James Ferguson, F. R. S.

"If the whole earth were transparent and hollow, like a sphere of glass, and had its equator divided into 24 equal parts, by so many meridian semi-circles, one of them being the geographical meridian of any given place, say London; and if the hours of XII. were marked on the equator, both on that meridian, and on its opposite one, and all the rest of the hours on the rest of the meridians, those meridians would be the hour-circles of London: then if the sphere had an opaque axis, terminating at its poles, the shadow of that axis would fall upon every particular meridian and hour, when the sun came to the plane of the opposite meridian; and would, consequently, shew the time at London, and at all the other places on the meridian of London."

DIALECTICS, in the literary history of the ancients, that branch of logics which taught the rules and modes of reasoning.

DIALLAGE, in mineralogy, called also resplendent hornblende. This stone was called *smaragdite* by Saussure, from its resembling the emerald. It is never crystallized. Its texture is foliated, and it is easily divided into plates. The laminæ are inflexible, and the specific gravity is 3. The colour in some cases is fine green; in others with a grey metallic lustre.

DIALING-*lines* or *scales*, are graduated lines placed on rulers or the edges of quadrants and other instruments, to expedite the construction of dials. These are, 1. A scale of six hours, which is only a double tangent, or two lines of tangents, each of 45°, set together in the middle, and equal to the whole line of sines, with the declination set against the meridian altitudes in the latitude of the place. 2. A line of latitudes, which is fitted to the hour-scale, and is made by this canon; As the radius: to the chord of 90° :: so are the tangents of each respective degree of the line of latitudes: to the tangents of other arcs. And then the natural sines of these arches are the numbers, which taken from a diagonal scale of equal parts, shall graduate the divisions of the line of latitudes to any radius. The lines of hours and latitudes are general, for pricking down all dials with centres.

The other scales are particular, and give the several requisites for all upright declining dials by inspection. They are, 1. A line of chords. 2. A line for the substile's distance from the meridian. 3 A line for the stile's height. 4. A line of the angle of 12 and 6. 5. A line of inclination of meridians.

DIALLING-*sphere*, an instrument made of brass, with several semicircles sliding over each other upon a moveable horizon, serving to demonstrate the nature of spherical triangles, as well as to give the true idea of drawing dials on all sorts of planes.

DIALIUM, a genus of the monogynia order, in the diandria class of plants. The corolla is pentapetalous; no calyx; the stamina at the upper side of the receptacle. There is one species, a tree of the East Indies.

DIAMETER, in geometry, a right line passing through the centre of a circle, and terminated at each side by the circumference, which it divides into two equal parts: hence we have a method of describing a semicircle upon any line, assuming its middle point for the centre. The diameter is the greatest of all chords.

How to find the diameter of shot or shells. For an iron ball, whose diameter is given, supposing a nine-pounder, which is nearly four inches, say the cube root 2.08 (of nine pounds,) is to four inches, as the cube root of the given weight, is to the diameter sought. Or, if 4 be divided by 2.08, the cube root of 9, the quotient 1.923 will be the diameter of a one-pound shot; which being continually multiplied by the cube root of the given weight, gives the diameter required. Or by logarithms much shorter, thus: If the logarithm of 1.923, which is .283979, be constantly added to the third part of the logarithm of the weight, the sum will be the logarithm of the diameter. Suppose a shot to weigh 24 pounds: and the given logarithm .283979 to .460070 the third part of the logarithm 1.3802112 of 24, the sum .7440494 will be the logarithm of the diameter of a shot weighing 24 pounds, which is 5.5468 inches.

If the weight should be expressed by a fraction, the rule is still the same: for instance, the diameter of a 1½ pound ball, or $\frac{3}{2}$, is found by adding the logarithm .2839793 found above, to .0586971 one-third of the logarithm of $\frac{3}{2}$; the sum .3426764 will be the logarithm of the diameter required, *i. e.* 2.2013 inches.

DIAMOND, is a precious stone, which has been known from the remotest ages. When pure, it is perfectly transparent like crystal, but much more brilliant. Its figure varies considerably; but most commonly it is crystallized in the form of a six sided prism, terminated by a six-sided pyramid. It is the hardest of all bodies; the best tempered steel makes no impression on it. Lustre, splendent, and internally perfect adamantine. Cleavage octohedral, or parallel to the sides of an octohedron. Foliated structure. Fragments octohedral or tetrahedral. Semitransparent. Refracts single. Scratches all known minerals. Rather easily frangible. Streak grey. Specific gravity 3.4 to 3.6. It consists of pure carbon, as we shall presently demonstrate. When rubbed, whether in the rough or polished state, it shews positive electricity; whereas rough quartz affords negative. It becomes phosphorescent on exposure to the sun or the electric spark, and shines with a fiery light. In its power of refracting light it is exceeded only by red lead-ore, and orpiment. It reflects all the light falling on its posterior surface at an angle of incidence greater than 24° 13′, whence its great lustre is derived. Artificial gems reflect the half of this light. It occurs in imbedded grains and crystals in a sandstone in Brazil, which rests on chlorite and clay-slate. In India the *diamond bed* of clay is underneath beds of red or bluish-black clay; and also in alluvial tracts both in India and Brazil.

The weight, and consequently the value of diamonds, is estimated in carats, one of which is equal to four grains; and the price of one diamond, compared to that of another of equal colour, transparency, purity, form, &c. is as the squares of the respective weights. The average price of rough diamonds that are worth working, is about L. 2 for the first carat. The value of a cut diamond being equal to that of a rough diamond of double weight, exclusive

of the price of workmanship, the cost of a wrought diamond of

1 carat is		L.8
2 do. is	$2^2 \times$ L.8, $=$	32
3 do. is	$3^2 \times$ L.8, $=$	72
4 do. is	$4^2 \times$ L.8, $=$	128
100 do. is	$100^2 \times$ L.8, $=$	80000.

This rule, however, is not extended to diamonds of more than 20 carats. The larger ones are disposed of at prices inferior to their value by that computation. The snow-white diamond is most highly prized by the jeweller. If transparent and pure, it is said to be of the first water.

DIAMOND, *brilliant*, is that which is cut in faces both at top and bottom; and whose table, or principal face at top, is flat.

DIAMOND, *rose*, is one that is quite flat underneath, with its upper part cut in many little faces, usually triangles, the uppermost of which terminate in a point. In rose-diamonds the depth of the stone from the base to the point must be half the breadth of the diameter of the base of the stone.

The largest diamond ever known in the world is one belonging to the king of Portugal, which was found in Brasil. It is still uncut: and Mr. Magellan informs us, that it was of a larger size: but a piece was cleaved or broken off by the ignorant countryman who chanced to find this great gem, and tried its hardness by the stroke of a large hammer upon the anvil. This prodigious diamond weighs 1680 carats: and though uncut, Mr. Romé de L'isle says that it is valued at 224 millions sterling; which gives the estimation of 79, 36 or about 80 pounds sterling for each carat, viz. for the multiplicand of the square of its whole weight. The famous diamond in the sceptre of the emperor of Russia, weighs 779 carats, and is worth at least 4,854, 728 pounds sterling, although it hardly cost 135,417 guineas. This diamond originally was one of the eyes of a Malabaric idol named Scheringham; and a French grenadier, who had deserted from the Indian service, contrived to become one of the priests of that idol, and by that means to steal it. After passing through several hands, the late Prince Orloff purchased it at Amsterdam in 1766, for his sovereign the empress of Russia. The diamond of the Great Mogul is cut in rose, weighs 279 $\frac{9}{16}$ carats, and is worth 380,000 guineas, though it has a small flaw near the bottom.

DIAMOND, in the glass trade, an instrument used for squaring the large plates or pieces; and, among glaziers, for cutting their glass. The diamonds are differently managed. That used for large pieces, as looking glasses, is set in an iron ferule, about two inches long, and a quarter of an inch in diameter; the cavity of the ferule being filled up with lead, to keep the diamond firm. there is also a handle of box or ebony fitted to the ferule, by which it is held.

DIANDRIA, the name of the second class in Linnæus's sexual system, consisting of hermaphrodite plants, which have flowers with two stamina or male organs. The orders in this class are three, derived from the number of styles or female parts. Most plants with two stamina have one style, as jessamine, lilac, privet, veronica, and bastard alaternus: vernal grass has two styles · pepper, three.

DIANTHERA, in botany, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 40th order, personatæ. The corolla is ringent; the capsule bilocular, parting with a spring at the heel; the stamina each furnished with two antheræ, placed alternately. There are 12 species.

DIANTHUS, clove-gilliflower, carnation, pink, sweet-william, &c. a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is cylindrical and monophyllous, with four scales at the base. There are five petals, with narrow heels; the capsule is cylindrical and unilocular. There are 30 species; but not more than four that have any considerable beauty as garden-flowers, each of which furnishes some beautiful varieties. Most of them are hardy, and perennial or biennial; some of the smaller wild sorts only are annual; stalks annual, from one to three feet in height; leaves opposite, narrow, entire; flowers terminating, many aggregate, some solitary, or several together, but distinct. This numerous genus includes the sweet-williams, carnations, and pinks, with their several varieties; for a full and complete account of which the reader is referred to Martyn's edition of Millar's botany.

DIAPASON, in music. By this term the ancient Greeks expressed the interval of the octave; and certain musical instrument-makers have a kind of rule or scale, called the diapason, by which they determine the measures of the pipes, or other parts of their instruments.

DIAPASON *diapente*, the interval compounded of an octave and a fifth conjoined; a twelfth.

DIAPASON *diatessaron*, the interval compounded of an octave and a fourth conjoined; an eleventh.

DIAPENSIA, in botany, a genus of the petandria-monogynia class of plants, the flower of which consists of one saucer-like petal, the tube being cylindrical, and the limb divided into five obtuse and plane segments; the fruit is a trilocular roundish capsule, containing a great many roundish seeds. There is one species.

DIAPHRAGM, in anatomy, a large robust, musculous membrane or skin, placed transversely in the trunk, and dividing the thorax from the abdomen, whence the Latin writers call it septum transversum.

DIARRHŒA, in medicine, is a disorder which consists of frequent evacuations by stool, and is often occasioned by a stoppage of perspiration, a cold in the feet, acrid substances in the stomach, &c.

DIASTOLE, among physicians, signifies the dilatation of the heart, auricles, and arteries; and stands opposed to the systole, or contraction of the same parts.

DIASTOLE, in grammar, a figure of prosody, whereby a syllable naturally short is made long: such is the first syllable of Priamides in the following verse of Virgil.

Atque hic Priamides: nihil o tibi, amice,
relictum.

DIATESSARON, among ancient musicians, a concord or harmonical interval, composed of a greater tone, a less tone, and one greater

semi-tone: its proportion in numbers is as 4 : 3. The word diatessaron has been of late used by several authors for a harmony of the four gospels.

DICERA, a genus of the polyandria monogynia class and order. The petals are four, ovate and trifid; nectarium four or five emarginate corpuscules; anthers two horned. There are two species, trees of New Zealand.

DICHONDRIA, a genus of the class and order pentandria digynia. The calyx is five-leaved; corolla rotate, inferior; capsule dicoccous. There is one species, a herb of New Zealand.

DICKSONIA, a genus of the class and order cryptogamia filices. There are two species, one of which is supposed to be the same with the baromets or Scythian lamb.

DICTAMNUS, white dittany, or fraxinella, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. The calyx is pentaphyllous; the petals are five and patulous; the filaments sprinkled with glandulous points; the capsules five, coalited. There are two species.

The dalbus, or fraxinella, has thick, penetrating, perennial roots, collected into a head at top, sending up erect stalks annually, two or three feet high, garnished with pinnated alternate leaves, of three or four pair of oblong stiff lobes, terminated by an odd one; and the stalks crowned by long, pyramidal, loose spikes of flowers, of white, red, and purple colours.

DICTIONARY, a collection, or catalogue, of all the words of a language, art, science, &c. with their explanations, ranged in alphabetical order.

DIDELPHIS, *opossum*, a genus of quadrupeds of the order of feræ. The generic character is: front teeth small, rounded, superior ten, the two middle ones longer; inferior eight, the two middle ones broader and very short; canine teeth long; grinders denticulated; tongue ciliated with papillæ; abdominal pouch, in most species, containing the teats.

These animals first became known to Europeans on the discovery of America, and excited their particular attention by a deviation in their structure from that of all other known quadrupeds. This singularity consisted in the female's possessing a bag or pouch in the lower part of the abdomen, which is opened and closed at pleasure, and to which her young resort for security in danger. Some females possess, according to Gmelin, two or three of these pouches, and the male is stated also occasionally to have one. These animals live in the woods, burrowing in the earth, and, by means of a prehensile tail, are alert in climbing trees. Their general motion is slow, and their food consists of insects, worms, and vegetables, young birds, and particularly poultry. They are by no means peculiar to the Western continent, but are to be found in various other parts of the world. According to both Shaw and Gmelin there are twenty-one species, of which the following are most deserving of attention.

1. *Didelphis Virginiana*, the Virginian opossum. The size of this animal is little inferior to that of the domestic cat; its tail is covered with a scaly skin, the divisions of which give it the resemblance of a small snake, and the animal has the faculty of coiling it round any object, and of thus increasing its means of defence and attack, and its facility of movement among the branches of trees. The teats of the female are inclosed in that astonishing receptacle which distinguishes almost every species of this animal; and immediately after their birth, the young are introduced by their parent to that cavity, or resort to it from an impulse of their own. In some species this cavity does not exist, and nature has substituted for it a sort of furrow. The Virginian opossum is gentle and inoffensive in its manners, but has a rank and disagreeable smell. The female produces four or five at a birth, and prepares a sort of nest for herself, of grass, near the root of a tree. She has the power of closing her pouch, and preserving it closed so completely as to render it a matter of great difficulty to open it. 2. *Didelphis marsupialis*, the Amboyna opossum, is found in the warmer climates of South America, as well as in some countries of the East. It is bred with rabbits in India, and passes, indeed, under the name of the Aroe rabbit. It is not only considered as fit for food, but regarded as a delicacy. This species is much larger than the last. 3. *Didelphis lemurina*, or the New Holland bear. The length of this animal's body is about a foot and a half, and that of its tail about a foot. It is, perhaps, the most elegant species of the genus. It has repeatedly been brought living to England. In its manners, or mode of subsistence, it resembles the other species; it is frequently perceived, however, to sit like a squirrel with its body erect, and holding its food in its hands. Its fur is extremely rich, soft, and thick. 4. *Didelphis petaurus*, or the great flying opossum of New Holland, is nearly two feet in length to the beginning of its tail, which is nearly two feet more. By an expansile membrane reaching on each side of its body, from the fore to the hind legs, it is enabled to leap to an extraordinary distance, and has thus gained the designation by which it is distinguished. Its fur is of the most exquisite fineness, and, for the greater part, of a sable or deep-grey brown colour, extremely brilliant. 5. *Didelphis sciurea*, or the squirrel opossum. This and the last species are considered by Shaw as the two most beautiful quadrupeds in New South Wales. Its general appearance extremely resembles that of a squirrel. Its fur is more soft and valuable than that of the flying opossum. Its abdominal pouch is rather beyond the usual proportion. This animal reposes by day, but during the night ranges in full activity.

DIDELTA, a genus of the class and order syngenesia polygamia frustranea. The calyx is expanding; receptacle honey-combed into parts, which retain the seeds; down, chaffy, many-leaved. There are two species, annuals of the Cape.

DIDUS, or *Dodo*, in ornithology, a genus belonging to the order of gallinæ. The bill is contracted in the middle by two transverse rugæ; each mandible is inflected at the point; and the face is bare behind the eyes. Only one species, the ineptus, is mentioned by Linnæus. Other naturalists have added two more

1. The dronte, or hooded dodo (ineptus, Lin.) is somewhat larger than a swan, and nearly three feet in length. The bill is strong,

large, and hooked at the end; the colour is a pale blue, except the end of the upper mandible, which is yellowish, and has a red spot on the bend of it; the end of the lower is blackish; the irides are white. The general colour of the plumage is cinereous. The head is large, and seems covered with a black hood or cowl. The wings are short, and of a yellowish ash-colour; the tail feathers are curled, stand up on the rump, and incline to yellow. The legs have four toes, three before and one behind. It inhabits the islands of Mauritius and Bourbon in the Indian ocean.

2. The soltaire, or solitary dodo, is a large bird, and the male is said to weigh sometimes 45 pounds. The neck is of a proportionable length and the eye black and lively; the head is not crested, and the general colour of the plumage is grey mixed with brown: it has scarcely any tail, and the bastard wing swells out into a round knob; the wings are too short for flight; and the hind parts are rounded like a horse's rump, being clothed with feathers, which may be termed coverts. According to Leguat, the bird has altogether a noble and elegant gait. This is an inhabitant of the isle of Rodrigue, where it is not uncommon. It makes its nest in by-places, of leaves of the palm, a foot and a half in thickness, and lays one egg. The male sits in his turn, and does not suffer any bird to approach within 200 yards of the spot while the hen is sitting, which is seven weeks.

3. The Nazarene dodo is larger than a swan. The bill is a little bent downwards, and large: instead of feathers, the whole is covered over with a black down: but the wings are feathered, and it has some frizzled ones upon the rump, which serve instead of a tail; the legs are long and scaly, and there are three toes on each foot. This was met with in the isle of France, and described as above by Fr. Cauche: who adds, that the female lays only one egg, which is white, and very large, and that there is always found with it a white stone generally about the size of a hen's egg; that it makes a nest of leaves and dry herbs in the forests on the ground; and that there is likewise found a grey stone in the gizzard of the young bird.

DIDYNAMIA, the name of the 14th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have four stamina or male organs, two of which are long and two short. See Botany.

DIFFERENCES, in heraldry, certain additaments to coat armour, whereby something is added or altered to distinguish younger families from the elder.

DIFFERENTIAL *calculus*. See Calculus differentialis.

DIGESTER. The digester is an instrument invented by Mr. Papin about the beginning of the last century. It is a strong vessel of copper or iron, with a cover adapted to screw on with pieces of felt or paper interposed. A valve with a small aperture is made in the cover, the stopper of which valve may be more or less loaded, either by actual weights, or by pressure from an apparatus on the principle of the steelyard.

The purpose of this vessel is to prevent the loss of heat by evaporation The solvent power of water when heated in this vessel is greatly increased.

DIGESTION, in animal economy. An important distinction exists between animals and vegetables, in the mode in which they receive their nourishment. Vegetables are constantly absorbing matter from the soil; it immediately passes into the sap vessels, and is soon changed by respiration and secretion. Animals, on the contrary, with very few exceptions, take in food at intervals, and retain it in their stomach for a considerable time, where it undergoes a chemical change, which constitutes the function of digestion, the first step in the general process by which animal matter is formed.

Digestion, in chemistry, an effect produced by the continued soaking of a solid substance in a liquid, with the application of heat.

DIGIT, digitus, in astronomy, the twelfth part of the diameter of the sun or moon, is used to express the quantity of an eclipse. Thus an eclipse is said to be of six digits, when six of these parts are laid.

Digit is also a measure taken from the breadth of the finger. It is properly three-fourths of an inch, and contains the measure of four barley corns laid breadth-wise.

Digits, in arithmetic, signify any integer under 10, as 1, 2, 3, 4, 5, 6, 7, 8, 9.

DIGITALIS, fox-glove, a genus of the angiospermia order, in the didynamia class of plants and in the natural method ranking under the 28th order, Luridæ. There are 12 species; 5 of which are hardy, herbaceous, biennial, and perennial plants. The herbaceous species rise two or three feet high, crowned with spikes of yellow iron-coloured or purple flowers. The canoriensis or shrubby sort rises five or six feet high, having spear-shaped rough leaves, the branches being terminated with flowers growing in loose spikes. All the species are easily raised by seeds. An ointment made of the flowers of purple fox-glove and fresh butter, is much commended for scrophulous ulcers. Taken internally, this plant is a violent purgative and emetic: and is therefore only to be administered to robust constitutions. An infusion of two drams of the leaf in a pint of water, given in half-ounce doses every two hours, till it begins to vomit or purge, is recommended in dropsy, particularly that of the breast.

DIGITATED, among botanists, an appellation given to compound leaves, each of which is composed of a number of simple foliola, placed regularly on a common petiole.

DIGYNIA, from δις *twice*, and γυνη *a woman*, the name of an order or secondary division, in each of the first 13 classes except the 9th, in Linnæus's sexual method; consisting of plants, which to the classic character whatever it is, add the circumstance of having two styles or female organs.

DILAPIDATION, is where an incumbent of a church-living suffers the parsonage house or out-houses to fall down, or be in decay, for want of necessary reparations; or it is the pulling down or destroying any of the houses or buildings belonging to a spiritual living.

DILATRIS, in botany, a genus of the mo-

gynia order, belonging to the triandria class of plants. There is no calyx; the corolla has six petals, and is shaggy; the stigma is simple. Three species, herbaceous plants of the Cape.

DILEMMA, in logic, an argument consisting of two or more propositions, which divides the whole into all its parts, or members, by a disjunctive proposition, and then infers something concerning each part, which is finally referred to concerning the whole.

DILLENIA, in botany, a genus of the polyandria-polygynia class of plants; the corolla which consists of five coriaceous, large, roundish, and hollow petals: the fruit is roundish, and covered with a number of capsules, which are oblong, and divided by a furrow; within, there is a large column or pulpous receptacle: the seeds are numerous, and small. There are seven species, beautiful trees of the East Indies.

DIMENSION, in geometry, is either length, breadth, or thickness; hence a line has one dimension, viz. length; a superficies, two, viz. length and breadth; and a body or solid has three, viz. length, breadth, and thickness.

Dimension is used with regard to the power of the roots of an equation, which are called the dimensions of that root.

DIMINUTION, in architecture, a contraction of the upper part of a column, by which its diameter is made less than that of the lower part.

Diminution in law, is where the pl[illegible] or defendant in a writ of error, alleges on an appeal to a superior court, that part of the record is omitted, and remains in the inferior court not certified; whereon he prays that it may be certified by certiorari.

Diminution, in music, is when there are several words which are to make tones, and several quick motions in a cadence, several quavers, semiquavers, &c. corresponding to a crochet or minim, as when a semibreve is divided into two minims, four crochets, &c.

Diminution, in rhetoric, the exaggerating what you have to say by an expression that seems to diminish it.

DIMINUTIVE, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus cellule is a diminutive of cell, globule of globe, hillock of hill.

DIMISSORY *letters*, are such as are used where a candidate for holy orders has a title in one diocese, and is to be ordained in another.

DIODIA, in botany, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped; the capsule bilocular and dispermous. There are six species.

DIODON, or sun-fish, a genus of fishes belonging to the order of amphibia nantes.

There are three species. 1. The atinga, grows to a great bulk; one examined by Sylvianus was above 100 pounds in weight; and Dr. Borlase mentions another taken at Plymouth, that weighed 500 pounds. In form it resembles a bream or some deep fish cut off in the middle. The mouth is very small, and contains in each jaw two broad teeth with sharp edges. The eyes are little, and the pectoral fins are very small, and placed behind them. The colour of the back is dusky and dappled; the belly silvery: between the eyes and the pectoral fins are certain streaks pointing downwards. The skin is free from scales. When boiled, it has been observed to turn into a glutinous jelly, resembling boiled starch when cold, and serving the purposes of glue on being tried on paper and leather. The meat of this fish is uncommonly rank: it feeds on shell-fish. 2. The mola, or short sun-fish, differs from the former, in being much shorter and deeper. The back and the anal fins are higher, and the aperture to the gills not semilunar, but oval. The situation of the fins is the same in both; they are taken on the western coasts of this kingdom. 3. The hystryx, or globe, is common to Europe and South Carolina. As yet only a single specimen has been discovered in our seas, taken at Penzance in Cornwall. The length was one foot seven; the length of the belly, when distended, one foot; the whole circumference in that situation two feet six. The form of the body is usually oblong; but when alarmed, it has the power of inflating its belly to a globular shape of great size. The belly and sides are white, shagreened or wrinkled: and beset with innumerable sharp spines, adhering to the skin by four processes.

DIŒCIA, two houses. The name of the 22d class in Linnæus's sexual method: consisting of plants which, having no hermaphrodite flowers, produce male and female flowers on separate roots. These latter only ripen seeds; but require for that purpose, according to the sexualists, the vicinity of a male plant; or the aspersion of the male dust. See Botany.

DIOMEDIA, in ornithology, the albatross, a genus belonging to the order of anseres. The bill is straight; the superior mandible is crooked at the point, and the lower one is truncated; the nostrils are oval, open, a little prominent, and placed on the sides. There are two species, viz. 1. The exulans, has pinnated wings, and three toes on each foot. It is the albatross of Edwards; is about the size of a pelican. These birds are found in the ocean betwixt the tropics and at the Cape of Good Hope. They are also often seen in vast flocks at Kamtschatka and the adjacent islands, about the end of June, where they are called great gulls. They are voracious birds, and will often swallow a salmon of four or five pounds weight; but as they cannot take the whole of it into the stomach at once, part of the tail-end will often remain out of the mouth; and the natives, finding the bird in this situation, make no difficult matter of knocking it on the head. Their nests are made on the ground with earth, are round in shape, a foot in height, and indented at top. The egg is larger than that of a goose, and is thought to be good food, the white never growing hard with boiling. While the female is sitting, the male is constantly on the wing and supplies her with food. 2. The demersa, has no quill-feathers on the wings; and the feet have four toes, connected together by a membrane. It is the black penguin of Edwards, about the size of a goose, and is found at the Cape of Good Hope. It is an excellent swim-

mer and diver; but hops and flutters in a strange awkward manner on the land, and if hurried, stumbles perpetually. It is said to climb some way up the rocks in order to make its nest; in doing which, it has been observed to assist with its bill. The eggs are two in number, white, as large as those of a duck.

DIONÆA *muscipula*, or Venus's fly-trap, in botany, a newly discovered sensitive plant, in the construction of which nature seems to have had some view towards its nourishment, in forming the upper joint of its leaf like a machine to catch food; and placing upon the middle of it the bait for the unhappy insect that becomes its prey. There is but one species, which is a native of North Carolina, and is found growing in swampy places.

DIOPHANTINE *problems*, in mathematics, certain questions relating to square and cube numbers, and right-angled triangles, &c. the nature of which was determined by Diophantus, of Alexandria, who lived about the third century. In these questions it is endeavoured to find commensurable numbers to answer indeterminate problems; which bring out an infinite number of incommensurable quantities. For example, it is proposed to find a right angled triangle, whose sides x, y, z, are expressed by commensurable numbers; it is known that $x^2+y^2=z$, z being the supposed hypothenuse. But it is possible to assume x and y so, that z will be incommensurable; for if $x=1$, and $y=2$. $z=\sqrt{5}$. The art of resolving such problems consists in managing the unknown quantity or quantities in such a manner, that the square or higher power may vanish out of the equation, and then by means of the unknown quantity in its first dimension, the equation may be resolved without having recourse to incommensurables.

For example, in the equation above, $x^2+y^2=z^2$, suppose $z=x+u$, then is $x^2+y^2=x^2+2xu+u^2$, out of which equation x^2 vanishes, and then it is $y^2=2xu+u^2$, which gives $x=\frac{y^2-u^2}{2u}$. Hence, assuming y and u equal to any numbers at pleasure, the three sides of the triangle will be y, $\frac{y^2-u^2}{2u}$, and $\frac{y^2+u^2}{2u}$, which are all rational whenever y and u are rational. For example, if $y=3$, and $u=1$, then $\frac{y^2-u^2}{2u}=4$, and $x+u$, or $\frac{y^2+u^2}{2u}$, $=5$. This problem admits of very numerous solutions.

DIOPSIS, a genus of the vermes class and of the diptera order. Head with two inarticulate filiform horns much longer than the head, at the tip of which are placed the eyes. It inhabits South America and Guinea, and resembles the ichneumon. There is but a single species.

DIOPTRICS, the science of refractive vision; or that part of optics which considers the different refractions of light in its passing through different mediums, as air, water, glass, &c. and especially lenses. See OPTICS.

DIOSCOREA in botany, a genus of the hexandria order, in the diœcia class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. There are 15 species, of which the only remarkable one is the sativa or yam. The roots are eaten by the inhabitants of both the Indies; and are particularly serviceable in the West India islands, where they make the greatest part of the food *of the negroes. The plant is supposed to have been brought from the East to the West Indies;* for it has never been observed to grow wild in any part of America; but in the island of Ceylon, and on the coast of Malabar, it grows in the woods. The skin of the roots is pretty thick, rough, unequal, covered with many stringy fibres or filaments, and of a violet colour. The inside is white, and of the consistence of red beet. It resembles the potatoe in its mealiness, but is of a closer texture. When raw, the yams are viscous and clammy: when roasted or boiled, they afford very nourishing food; and are often preferred to bread by the inhabitants of the West Indies. The root commonly weighs two or three pounds, though some yams have weighed upwards of twenty pounds.

DIOSMA, AFRICAN SPIRÆA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. There are 19 species; of which the most remarkable are the hirsuta, with narrow hairy leaves; and the oppostifolia, with leaves placed in the form of a cross. The first is a very handsome shrub, growing to the height of five or six feet: the stalks are of a fine coral colour. the leaves come out alternately on every side of the branches, and the flowers are produced in small clusters at the end of the shoots, and are of a white colour. They are succeeded by starry seed-vessels having five corners; in each of which corners is a cell, containing one oblong, black seed: these seed-vessels abound with a resin which emits a grateful scent, as does also the whole plant. The second species rises to the height of three or four feet: the branches are slender, and produced from the stem very irregularly; the leaves are placed cross-wise; the flowers are produced at the ends of the branches, between the leaves: the plants continue a long time in flower, and make a fine appearance when intermixed with other exotics in the open air.

DIOSPYROS, the INDIAN DATE-PLUM; a genus of the diœcia order, in the polygamia class of plants; and in the natural method ranking under the 18th order, bicornes. There are 9 species; the most remarkable are: 1. The lotus, which is supposed to be a native of Africa, whence it was transplanted into Italy, and the south of France. In the warm parts of Europe, this tree grows to the height of 30 feet. This tree produces plenty of fruit every year; from the seeds of which many plants have been raised. 2. The Virginiana, pinshamin, persimon, or pitchumon plum, is a native of America, but particularly of Virginia and Carolina. The seeds of this sort have been frequently imported into Britain, and the trees are common in many nurseries about London. It rises to the height of 12 or 14 feet; but generally divides into many irregular trunks near the ground. In America the inhabitants preserve the fruit till it is rotten, as is practised with medlars in England; when it is esteemed very pleasant.

DIP, of the horizon, is an allowance made in all astronomical observations of altitude for the height of the eye above the level of the sea.

DIPHTHONG, in grammar, a double vowel, or the mixture of two vowels pronounced together, so as to make one syllable.

DIPHYSA, a genus of the class and order diadelphia decandria. The calyx is half five-cleft; legume with a bladder on each side; seeds hooked. There is one species, a small tree of New Spain.

DIPLOMA, an instrument or licence given by colleges, societies, &c. to a clergyman to exercise the ministerial function, or to a physician to practise the profession, &c. after passing examination, or admitting him to a degree.

DIPPING *needle*. See MAGNETISM and NAVIGATION.

DIPSACUS, TEAZEL, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 48th order, aggregate. The common calyx is polyphyllous, proper above; the receptacle paleaceous. There are four species; the most remarkable of which is the dipsacus fullonum, which grows wild in many parts of England. It is much used in raising the nap upon woollen cloth. For this purpose, the heads are fixed round the circumference of a large broad wheel, which is made to turn round, and the cloth is held against them. In the west of England, great quantities of this plant are cultivated for the use just mentioned.

DIPTERA, in natural history, an order of insects in the Linnæan system. This order contains such insects as are furnished with two wings only; such as flies, gnats, and a variety of other insects. Under each wing is a clavate poiser or balancer, with its appropriate scale.

DIPUS, JERBOA, a genus of quadrupeds of the glires order. The generic character is, front-teeth two above and below: fore-legs very short; hind-legs very long: clavicles in the skeleton.

1. Dipus sagitta, or common jerboa. It is about the size of a rat, and is of a pale tawny-brown above, and white beneath; and across the upper part of the rump runs a dusky band. The head is short; the ears thin, broad, upright, and rounded: the eyes large, round, and dark; the fore-legs about an inch long, with five toes to each foot; the hind-legs are extremely long, thin, sparingly covered with short hair, and very much resemble those of a bird: the hind feet have three toes each, the middle longer than the rest, and all are furnished with sharp claws: there is also a very small spur or back toe, with its corresponding claw.

The usual length of the common jerboa, from nose to tail, is about seven inches and a quarter: the tail is about ten inches long, terminated by a flattish tuft of black hair, with a white tip. On each side the nose are situated several very long hairs or whiskers. In its attitudes and manner of progression this animal resembles a bird: generally standing, like the kangaroo, on its hind feet, and leaping to a great distance. It principally uses the fore-legs in feeding; pulling to its mouth the ears of corn, and various other vegetable substances on which it feeds. It inhabits subterraneous holes, which it either prepares itself, or finds ready excavated, in the dry, stony, and sandy deserts in which it resides. During the day it commonly remains in its hole; coming out at night for food and exercise. On the approach of cold it is said to grow torpid for some time, reviving on the change of weather.

2. Dipus jaculus, or alagtaga, in its general appearance perfectly resembles the common or Egyptian jerboa, but is considerably larger. It is principally distinguished by the remarkable character of the hind feet, each of which has a pair of very conspicuous spurs, or additional toes, situated at some distance above the front toes, and furnished with sharp claws.

Of this species there are two supposed varieties, agreeing in form with the above-mentioned, but differing in size, and in some degree in colour; but the differences are not such as to justify our considering them as specifically distinct. The first of these varieties is the Middle Siberian jerboo, which is of the size of a rat, and has the thighs crossed by a white line; and a whitish zone or circle surrounding the nose.

It is found in the eastern deserts of Siberia and Tartary, beyond the lake Baikal. The other variety is called by Mr. Pennant, the pigmy Siberian jerboa. It agrees in form with the other, but has no white circle round the nose, and has a smaller tuft to the tail, the end of which is tipped with white. In size it is inferior to the middle variety. It is said to inhabit the same places with the large or first described kind.

3. Dipus cafer, or cape jerboa, is by far the largest of all the jerboas, and is a native of the mountainous country to the north of the Cape of Good Hope. It is an animal of great strength and activity, and will spring to the distance of 20 or 30 feet at once. When eating, it sits upright in the manner of a squirrel.

4. Dipus meridianas, or torrid jerboa, according to Dr. Pallas, was first figured by Seba, whose specimen appears to have been not fully grown. Specimens were brought to Dr. Pallas in the year 1770, which were taken on the borders of the sandy desert of Naryn, in 46½° north latitude. The burrows or passages which they had formed in the dry soil, had a triple entrance, and were about an ell deep in the ground. The size of this species is between that of a rat and a field-mouse.

5. Dipus Canadensis, or Canadian jerboa. This minute species is thus described by General Davies, who had an opportunity of examining it during his residence at Quebec.

"During the time the animal remained in its usual vigour, its agility was incredible for so small a creature. It always took progressive leaps of from three to four, and sometimes of five yards, although seldom above 12 or 14 inches from the surface of the grass; but I have frequently observed others in shrubby places, and in the woods, among plants, where they chiefly reside, leap considerably higher. When found in such places, it is impossible to take them, from their wonderful agility, and their evading all pursuit, by bounding into the thickest part of the covert they can find."

DIRCA, a genus of the monogynia order, in the octandria class of plants, and in the

natural method ranking under the 1st order, vepreculæ. There is one species, a small shrub of North America.

DIRECTION, in mechanics, signifies the line or path of a body's motion, along which it endeavours to proceed, according to the force impressed upon it.

DISA, a genus of the gynandria diandria class and order. The spathe is one-valved; petals three, the third less, two-parted, gibbous at the base. There are four species, herbaceous plants of the Cape, with beautiful blue flowers.

DISANDRA, a genus of the monogynia order, in the heptandria class of plants. The calyx has seven leaves; the corolla is parted into seven, and flat; the capsule two-celled. There are two species, pretty trailling plants, natives of Madeira.

DISC, *discus*, in antiquity, a quoit made of stone, iron, or copper, five or six fingers broad, and more than a foot long, inclining to an oval figure, which was hurled in the manner of a bowl, to a vast distance, by the help of a leathern thong tied round the person's hand who threw it, and put through a hole in the middle.

Disc, in astronomy, the body and face of the sun and moon, such as it appears to us on the earth; or the body or face of the earth, such as it appears to a spectator in the moon. The disc in eclipses is supposed to be divided into 12 equal parts, called digits; in a total eclipse of the luminaries, the whole disc is obscured; in a partial eclipse, only a part of it. See Astronomy.

DISCORD, in music, a dissonant and inharmonious combination of sounds, so called in opposition to the concord.

DISCOUNT, a compensation for the advance of money which is not due till after a certain period. The person advancing the money, had he retained it, might have made in the given time a certain rate of interest; therefore if he advances it for the use of another, it is equitable that he should be allowed the same gain as he would have made by retaining it in his own hands during the time for which it is lent. Thus, if a person is entitled to 100*l.* at the end of a year, and has occasion for the money immediately, the sum that ought to be given as an equivalent thereto, allowing 5 per cent. interest, is 95*l.* 4*s.* 9¼*d.*; for the discount of 4*l.* 15*s.* 2¾*d.* which is then retained, will, if improved at 5 per cent interest, amount at the end of a year to 5*l.* and consequently the lender having then 105*l.* will have made the same gain as he would have made by retaining the money. This is the true principle of discount, according to which the tables published by Mr. Smart are computed; but in commercial transactions, the general mode is, to deduct from the sum to be discounted, the simple interest on that sum for the time for which it is advanced. Thus, if 100*l.* is payable at the end of six months, the discount deducted is 2*l.* 10*s.* being the half of a year's interest; or, if 100*l.* is payable at the end of one month, the discount deductod is 8*s.* 4*d.* being the twelfth part of a year's interest. By this means, although the legal rate of interest to be received for money lent is restricted to 5 per cent, the person who employs his money in disconnting, makes a greater rate of interest, and the shorter the periods are for which he discounts, the greater his annual gains. In discounting bills of exchange, the days of grace are included in the time the bill has to run, the discount being calculated to the day on which the money is receivable.

DISCRETE, or *Disjunct Proportion*, is when the ratio of two or more pairs of numbers or quantities is the same, but there is not the same proportion between all the four numbers.

Discrete *quantity*, such as is not continuous and joined together. Such is a number whose parts being distinct units, cannot be united into one continuum; for in a continuum, there are no actual determinate parts before division, but they are potentially infinite.

DISJUNCTIVE *proposition*, in logic, is that where of several predicates we affirm one necessarily to belong to the subject to the exclusion of all the rest, but leave that particular one undetermined.

DISPENSARY, a charitable institution, very common in London and some other large towns of Britain. They are supported by voluntary subscriptions, and each has one or more physicians, surgeons, and apothecaries, who attend, or ought to attend at stated times, in order to prescribe for the poor, and if necessary to visit them at their own habitations. The poor are supplied with medicines gratis. Where these institutions are managed with care they are of the utmost importance to society, it being unquestionably more for the comfort of the sick to be attended at their own houses, than to be dragged from their families to an hospital.

DISPENSATORY, denotes a book containing the method of preparing the various kinds of medicines used in pharmacy. Such are the London, Edinburgh, and Dublin Pharmacopæias.

DISSECTION, in anatomy, the cutting up a body with a view of examining the structure and use of the parts. See Anatomy.

DISSEISIN, in law, is a wrongful putting out of him that is seized of the freehold, which may be effected either in corporeal inheritances, or incorporeal. Disseisin of things corporeal, as of houses and lands, must be by entry and actual dispossession of the freehold. Disseisin of incorporeal hereditaments, cannot be an actual dispossession, for the subject itself is neither capable of actual bodily possession nor dispossession, but is only at the election and choice of the party injured, if, for the sake of more easily trying the right, he is pleased to suppose himself disseised. And so also even in corporeal hereditaments, a man may frequently suppose himself to be disseised, when he is not so in fact, for the sake of entitling himself to the more easy remedy of an assise of novel disseisin, instead of the process of a writ of entry.

DISSIPATION, *circle of*, in optics, is used for that circular space upon the retina, which is taken up by one of the extreme pencils or rays issuing from an object. To understand this, it is to be observed, that when the distance of an object from the eye is too small or too great for perfect or distinct vision, the rays of each pencil, issuing from the object, cannot be united at a point on the retina, but beyond it, or before they arrive at the retina; consequently, the rays of each pencil will occupy a

circular space upon the retina, and this circle is called the circle of dissipation, because the rays of a pencil, instead of being collected into a central point, are dissipated all over this circle.

DISSOLVENT, in general, whatever dissolves or reduces a solid body into such minute parts as to be sustained in a fluid.

DISSOLUTION, in music, is when a sound in the enharmonic genus is lowered three dieses; for thereby that genus is dissolved, and the music, or that interval at least, is chromatic.

DISTANCE, in general, an interval between two things, either with regard to time or place. See GEOMETRY and MENSURATION.

DISTANCE, in navigation, the number of minutes or leagues a ship has sailed from any given place or point.

DISTANCE, in astronomy. The distance of the sun, planets, and comets, is only found from their parallax, as it cannot be found either by eclipses or their different phases, for from the theory of the motions of the earth and planets we know, at any time, the proportion of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to these distances.

DISTEMPER, in painting, a term used for the working up of colours with something besides water or oil. If the colours are prepared with water, that kind of painting is called limning; and if with oil, it is called painting in oil, and simply painting. If the colours are mixed with size, white of eggs, or any such proper glutinous or unctuous matter, and not with oil, then they say it is done in distemper. In this manner the admirable cartoons at Hampton-court are painted.

DISTICH, a couplet of verses making a complete sense. Thus hexameter and pentameter verses are disposed in distichs.

DISTILLATION, is properly a chemical process by which one body is separated from another, by taking advantage of the relative temperatures at which they assume the elastic form, and afterwards condensing the vapour in a separate vessel. For distillation on a small scale, the simplest apparatus that can be used is the common glass retort, with its receiver; next to this is the alembic which may be made of tinned iron; but if it is required to carry the process to any extent, a still with worm, and suitable accompaniments will be necessary. As these implements will be described under the article LABORATORY, it may suffice to give here an example of the process as carried on in the regular distilleries of this country. The following is the method used by the Scotch distillers in the production of malt whisky.

In making malt whisky, one part of bruised malt, with from four parts to nine of barley-meal, and a proportion of seeds of oats corresponding to that of the raw grain, is infused in a mash-tub of cast iron, with from 12 to 13 wine gallons of water, at 150° Fahr. for every bushel of the mixed farinaceous matter. The agitation then given by manual labour or machinery to break down and equally diffuse the lumps of meal, constitutes the process of *mashing*. This operation continues two hours or upwards, according to the proportion of unmalted barley; during which the temperature is kept up by the affusion of seven or eight additional gallons of water, a few degrees under the boiling temperature. The infusion, termed *wort*, having become progressively sweeter, is allowed to settle for two hours, and is run off from the top, to the amount of about one-third the bulk of water employed. About eight gallons of more water, a little under 200° F. are now admitted to the residuum, *infused* for nearly half an hour with agitation, and then left to subside for an hour and a half, when it is drawn off. Sometimes a third affusion of boiling water, equal to the first quantity, is made, and this infusion is generally reserved to be poured on new *farina;* or it is concentrated by boiling, and added to the former liquors. In Scotland, the distiller is supposed by law to extract per cent 14 gallons of spirits, sp. gr. 0.91917, or 1 to 10 over proof, and must pay duty accordingly. Hence, his wort must have at least the strength of 55¼ pounds of saccharine matter per barrel, previous to letting it down into the fermenting tun; and the law does not permit it to be stronger than 75 pounds. Every gallon of the above spirits contains 4.6 pounds of alcohol, sp. gr. 0.825, and requires for its production the complete decomposition of twice 4.6 pounds of sugar = 9.2 pounds.

To prevent acetification, it is necessary to cool the worts down to the proper fermenting temperature of 70° or 65° as rapidly as possible. Hence, they are pumped immediately from the mash-tub into extensive wooden troughs, two or three inches deep, exposed in open sheds to the cool air; or they are made to traverse the convolutions of a pipe immersed in cold water. The wort being now run into the fermenting tun, yeast is introduced and added in nearly equal successive portions during three days, amounting in all to about one gallon for every two bushels of farinaceous matter. The temperature rises in three or four days to its maximum of 80°; and at the end of 10 or 12 days the fermentation is completed, the tuns being closed up during the last half of the period. The distillers do not collect the yeast from their fermenting tuns, but allow it to fall down, on the supposition that it enhances the quantity of alcohol.

In distilling off the spirit from the fermented wort or wash, a hydrometer is used to ascertain its progressive diminution of strength; and when it acquires a certain weakness, the process is stopped by opening the stop-cock of the pipe which issues from the bottom of the still, and the spent wash is removed. There is generally introduced into the still a bit of soap, whose oily principle spreading on the surface of the boiling liquor, breaks the large bubbles, and of course checks the tendency to froth up.

DISTRESS, in law, is the taking of a personal chattel, out of the possession of the wrong doer, into the custody of the person who is injured, to procure a satisfaction for the wrong committed. It is of two kinds: cattle for trespassing and doing damage, or for non-payment of rent or other duties. But the most usual injury for which a distress may be taken, is that of non-payment of rent.

DIVER, in ornithology. See COLYMBUS.

DIVERGENT, or *diverging lines*, in geometry, are those which constantly recede from each other.

Divergent *rays*, in optics, are those which, going from a point of the visible object, are dispersed, and continually depart one from another, in proportion as they are removed from the object: in which sense it is opposed to convergent. See Optics.

DIVIDEND, in arithmetic, the number proposed to be divided into equal parts. It must always be greater than the divisor.

Dividend *of stocks*, is a share or proportion of the interest of stocks erected on public funds, as the South Sea, &c. divided among, and paid to, the proprietors half-yearly.

DIVING, the art or act of descending under water to considerable depths, and abiding there a competent time. The uses of diving are very considerable, particularly in the fishing for pearls, corals, sponges, &c.

Various methods have been proposed, and engines contrived, to render the business of diving more safe and easy. The great point in all these is, to furnish the diver with fresh air, without which he must either make but a short stay, or perish.

Those who dive for sponges in the Mediterranean, help themselves by carrying down sponges dipped in oil in their mouths. But considering the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the pressure of the incumbent water, such a supply cannot long subsist the diver. And it has been found by experiment that a gallon of air included in a bladder, and by a pipe reciprocally inspired and expired by the lungs, becomes unfit for respiration in little more than one minute of time. For though its elasticity is but little altered in passing the lungs, yet it loses its oxygen, and is rendered unfit for respiration.

The original diving bell was a very imperfect machine, affording the diver no supply of fresh air while under water. This difficulty was first obviated by Dr. Halley's contrivance of an apparatus for lowering casks of air, from which, by means of a pipe, the diver had a constant supply, and was thus enabled to keep the water out of the bell, and to continue much longer at the bottom.

Several improvements were gradually made in the construction of this machine, while the method of supplying it with air continued nearly the same, until the method attributed to Mr. Smeaton, but claimed by others, was applied with great success. This improvement consisted of a strong leathern pipe, which was connected with the top of the bell to convey air into it from an air-pump placed either in a boat or on the shore.

The celebrated Mr. Rennie has farther improved this principle by the application of a powerful double barrelled air-pump. His diving bell is made of cast iron, having strong lenses inserted in it for the admission of light. Several workmen are enabled to descend in it together, and to carry on the operations of clearing the ground; cutting and blasting rocks; and rearing structures of prodigious magnitude in deep water, with nearly as great facility as on land.

This bell may, by the aid of a vessel fitted up for the purpose, be moved about, and made to sweep over the bottom; it has been thus used in Plymouth sound to discover and take up old anchors, &c.

It is but justice to mention here that on the failure of Dr. Halley's diving bell in Dublin bay, on which occasion two men lost their lives by the bell becoming entangled in its descent, the greater part of the wreck saved from the rich ship Belgiosa, was taken up by means of a bell invented by the late Mr. Adam Walker. Its construction is extremely simple, and in many respects it resembles Mr. Rennie's. We shall here add a brief description of the ingeniously contrived diving bell of Mr. Spalding of Edinburgh, represented in Plate X. Mr. Walker's, which is represented on the same plate, requires no description after what has been said above.

A B C D fig 3, represents a section of the bell which is made of wood, *ee* are iron hooks, by means of which it is suspended by ropes Q B F *e* and Q A E *e* and Q S as expressed in the figure; *cc* are iron hooks, to which are appended leaden weights, that keep the mouth of the bell always parallel to the surface of the water, whether the machine is lighter or heavier than an equal bulk of water. By these weights alone, however, the bell would not sink, another is therefore added, represented at L, and which can be raised or lowered at pleasure, by means of a rope passing over the pulley *a*, and fastened to the sides of the bell M. As the bell descends, this weight, called the balance weight, hangs down a considerable way below the mouth of the bell. In case the edge of the bell is caught by any obstacle, the balance weight is immediately lowered down, so that it may rest upon the bottom, by this means the bell is lightened, and all danger of oversetting is removed, for being lighter without the balance weight than an equal bulk of water, it is evident that the bell will rise as far as the length of the rope affixed to the balance weight will allow it.

By another very ingenious contrivance, Mr. Spalding rendered it possible for the divers to raise the bell with all the weights appended to it, even to the surface, or to stop at any particular depth as they think proper; for this purpose, the bell is divided into two cavities, both of which are made as tight as possible; just above the second bottom, E F, are small slits on the sides of the bell through which the water entering as the bell descends, displaces the air originally contained in its cavity, which flies out at the upper orifice of the cock H. When this is done, the divers turn the handle which stops the cock, so that if any more air was to get into the cavity A E F B, it could no longer be discharged through the orifice H as before. When this cavity is full of water, the bell sinks, but when a considerable quantity of air is admitted, it rises. If therefore the divers have a mind to raise themselves, they turn the small cock, by which a communication is made between the upper and under cavities of the bell; the consequence of this is, that a quantity of air immediately enters the upper cavity, forces out a quantity of water contained in it, and thus renders the bell lighter by the whole weight of the water which is displaced. Thus if a certain quantity of air is admitted into the upper cavity, the bell will descend very slowly; if a greater quantity, it will neither ascend nor descend, but remain stationary; and if a larger

quantity of air be still admitted, it will rise to the top.

Instead of wooden seats, used by Dr. Halley, Mr. Spalding made use of ropes suspended by hooks *b, b, b,* and on these ropes the divers may sit without any inconvenience,

[illegible]

flexible [illegible]ough which the air is admitted to the bell in the ascent and descent of this cask, the pipe is kept down by a small appended weight, as in Dr. Halley's machine; R is a small cock by which the hot air is discharged.

Mr. Spalding is of opinion, that one air-barrel, capable of containing thirty gallons, is sufficient for an ordinary machine.

In fig. 1 and 2, are shewn representations of a frame for supporting a diving bell, and transporting it from place to place upon the water. Fig. 1, is a side elevation, and fig. 2, a section of it. The same letters refer to both figures. A B, fig. 2, are sections of two barges, such as are used upon the Thames, at London: D E F, is a frame lying across the barges, and supporting a beam, G, from which hangs a strong block for the rope by which the bell, H, is suspended; the other end of the rope goes round a windlass, *a*, with a rachet wheel and click to raise and lower the bell as occasion requires: *b d* are smaller blocks, for the ropes to draw up the air barrels; *e f* are rollers, turned by winches, fixed on the opposite barge to the windlass, *a:* the ropes are wound round these rollers in contrary directions, and the winches come close together, so that one man can turn them both at once, and when one rope descends, the other ascends, so as to give a constant supply of air to the divers under the bell H. When the divers wish to come up, they give a signal to that purpose, and the windlass is turned by men, until the bottom of the bell is brought above water; a small boat or raft is rowed under the bell to take the divers out: the same method is to be used to get them in, and this will be done without wetting them. Several small bells of very different tones should be fixed to the beam G, and strings fastened to them should go into the bell for the divers to ring, as signals to the workmen in the barges above. The barges should be well secured together by cross beams.

DIVISIBILITY, that property by which the particles of matter in all bodies are capable of a separation, or disunion from each other.

As it is evident that body is extended, so it is no less evident that it is divisible; for since no two particles of matter can exist in the same place, it follows, that they are really distinct from each other, which is all that is meant by being divisible. In this sense the least conceivable particle must still be divisible, since it will consist of parts which will be really distinct. To illustrate this by a familiar instance, let the least imaginable piece of matter be conceived lying on a smooth plain surface, it is evident the surface will not touch it every where: those parts, therefore, which it does not touch, may be supposed separable from the others, and so on, as far as we please; and this is all that is meant when we say matter is infinitely divisible.

The difference of opinion that exists among philosophers on this point is not likely to be finally removed so long as mankind remain in ignorance respecting the immediate connexion between the existence of matter and the great first cause of its existence. The term *infinite,*

[illegible] imagination itself is limited.

DIVISION, in arithmetic, one of the four fundamental rules, by which we find how often a less number, called the divisor, is contained in a greater, called the dividend; the number of times which the divisor is contained in the dividend being termed the quotient.

Division, in the sea language, the third part of a fleet of men of war, and sometimes the ninth part; which last happens when the fleet is divided into three squadrons: for then each squadron is distributed into three divisions.

DIVORCE, a separation of two *de facto* married together, of which there are two kinds; one *a vinculo matrimonii*, from the very bond of marriage; the other *a mensa et thoro* from bed and board.

DIURETICS, in pharmacy, such medicines as increase the discharge of urine; or which are supposed to have a power of removing obstructions in the urinary passages.

DIURNAL *arch*, the arch or number of degrees that the sun, moon, or stars, describe between their rising and setting.

Diurnal *motion of a planet*, is so many degrees and minutes as any planet moves in 24 hours. Hence the motion of the earth about its axis is called its diurnal motion.

DOCK, in maritime affairs, is an artificial bason, by the side of an harbour, made convenient either for the building or repairing of ships. It is of two sorts, 1. Dry-dock, where the water is kept out by great flood-gates, till the ship is built or repaired, when the gates are opened, and the water let in to float and launch her. 2. Wet-dock, a place where the ship may be hauled into, out of the tide's way, and so dock or sink herself a place to lie in.

Dock-*yards*, in ship-building, are magazines of all sorts of naval stores. The principal in England are those of Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace ships of war are laid up in these docks; those of the first-rate mostly at Chatham, where, and at other yards, they receive from time to time such repairs as are necessary. These yards are generally supplied from the northern powers with hemp, pitch, tar, rosin, &c. but as for masts, particularly those of the larger size, they are brought from America.

DOCTOR, a person who has passed all the degrees of a faculty, and is impowered to teach or practise the same: thus we say, doctor in divinity, doctor in physic, doctor of laws.

The title of doctor seems to have been created in the twelfth century, instead of master, by Peter Lombard and Gilbert Porreus, then the chief divines of the University of Paris.

To pass doctor in divinity at Oxford, it is necessary the candidate have been four years batchelor of divinity. For doctor of laws, he

must have been seven years in the university to commence batchelor of law, five years after which he may be admitted doctor of laws.

At Cambridge, to take the degree of doctor in divinity, it is required the candidate have been seven years batchelor of divinity: though in several colleges the batchelor's degree is dispensed with, and they may go out *per saltum*.

DODARTIA, a genus of the didynamia angiospermia class and order of plants, the flower of which consists of one ringent petal, with the upper lip erect and semibifid; and the lower lip patent, twice broader than long, and trifid. There are two species, herbaceous plants of the East.

DODECAGON, in geometry, a regular polygon, consisting of twelve equal sides and angles.

DODECAHEDRON, in geometry, one of the Platonic bodies, or regular solids, contained under twelve equal and regular pentagons.

Its solidity is found by multiplying the area of one of the pentagons by 12, and then this product by one-third of the distance of the face from the centre of the dodecahedron, which is the same with the centre of the circumscribing sphere.

The side of a dodecahedron, inscribed in a sphere, is the greater part of the side of a cube, inscribed in the same sphere, cut into extreme and mean proportion. If the diameter of the sphere be 1.0000, the side of the dodecahedron, inscribed in it, will be .35682 nearly.

All dodecahedrons are similar, and are to one another as the cubes of their sides; their surfaces are also similar, and therefore they are as the squares of their sides.

DODECANDRIA, the name of the 11th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, that, according to the title, have twelve stamina. [illegible] class, however, is not limited with respect to the number of stamina. Many genera have sixteen, eighteen, and even nineteen.

DODECAS, a genus of the trigynia order, in the dodecandria class of plants. The calyx is half-quadrifid, having the corolla above; the corolla quinquefid; the capsule unilocular, conjoined with the calyx. There is but one species, a shrub of Surinam.

DODECATHEON, a genus of the monogynia order, in the pentandria class of plants, [illegible] in the natural method ranking under the 21st order, preciæ. There is one species, the D. media, a perennial plant, a native of Virginia.

DODO. See DIDUS.

DODONÆA, a genus of plants of the octandria monogynia class: it has no corolla; the fruit is a roundish trilocular capsule, with prominent inflated angles, containing solitary seeds. There are two species.

DOG, in zoology. See CANIS.

DOLICHOS, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. Essential character: two parallel oblong calluses at the base of the standard, compressing the wings underneath. There are thirty-eight species; most of these are annual and natives either of the East or West Indies. They are chiefly herbaceous, with twining stalks; the flowers are frequently in spikes, and axillary; the legume is often smooth, sometimes villose, or pruinent. Mr. Millar affirms that he has cultivated more than sixty, besides many varieties.

DOLIOCARPUS, a genus of the polyandria monogynia class and order. The calyx is five-leaved; corolla three-petalled, plaited; stigma subtrifid; berry globular, crowned; with the style, one-celled, two-seeded. There are three species, shrubs of Guiana.

DOLPHIN. See DELPHINUS.

DOMBEYA, a genus of the class and order diœcia monadelphia. The male, calyx of the ament scales; corolla none; anthers 10 or 12, without filaments. Female, calyx ament with many germs; corolla none; stigma bivalve, unequal; seeds many, in a roundish strobile. There is one species, a tree of Chili.

DOME. See ARCHITECTURE.

DOMESDAY, is a record, made in William the Conqueror's time, and now remaining in the Exchequer, fair and legible, consisting of two volumes, containing a survey of all the lands in England. It was begun by five justices, assigned for that purpose in each county, in the year 1081, and finished in 1086.

DOMINICAL *letter*, in chronology, is that letter of the alphabet which points out in the calendar the Sundays throughout the year, thence also called Sunday-letter. The distribution of days into weeks is made by the seven first letters of the alphabet A, B, C, D, E, F, G, beginning, at the first of January, to place the letter A; to the second of January B is joined; to the third C; and so on to the seventh, where G is figured; and then again beginning with A, which is placed at the eighth day, B will be at the ninth, C at the tenth, and so continually repeating the series of these seven letters, each day of the year has one of them in the calendar.

DONATIA, a genus of the trigynia order, in the triandria class of plants. There is one species.

DONAX, a genus of insects belonging to the order of vermes testacea. It is an animal of the oyster kind; and the shell has two valves, with a very obtuse margin in the fore-part. There are 10 species, principally distinguished by the figure of their shells.

DORÆNA, a genus of the pentandria monogynia class and order. There is one species, a dwarf tree about six feet high, a native of Japan.

DORIC *order*, in architecture, the second of the five orders, being that between the Tuscan and Ionic. See ARCHITECTURE.

DORIC *dialect*, in grammar, one of the five dialects, or manners of speaking, which were principally in use among the Greeks.

DORIS, a genus of insects, belonging to the order of vermes testacea. There are several species. The argo, or lemon doris, has an oval body, convex, marked with numerous punctures, of a lemon colour, the vent beset with elegant ramifications. It inhabits different parts of our seas, and is properly called the sea-lemon.

DORMANT, in heraldry, is used for the

posture of a lion, or any other beast, lying along in a sleeping attitude, with the head on the fore paws; by which it is distinguished from the couchant.

DORMOUSE, in zoology. See Mus, and Sciurus.

DORONICUM, *leopard's bane*; a genus of the polygamia superflua order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There are three species; of which the only one worthy of notice is the pardalianches, with obtuse heart-shaped leaves. It grows naturally in Hungary, and on the Helvetian mountains; but is frequently preserved in the English gardens. It has thick fleshy roots, which divide into many knobs or knees, sending out strong fleshy fibres which penetrate deep into the ground; from these arise in the spring a cluster of heart-shaped leaves, which are hairy and stand upon footstalks: between these arise the flowerstalks, which are channelled and hairy, nearly three feet high, putting out one or two smaller stalks from the side. Each stalk is terminated by one large yellow flower. The plant multiplies very fast by its spreading roots; and the seeds, if permitted to scatter, will produce plants wherever they happen to fall.

DORSAL *muscles*, are the muscles of the back and loins, which are for the most part common.

DORSIFEROUS *plants*, among botanists, such as are of the capillary kind, without stalks, and which bear their seeds on the back-side of their leaves.

DORSTENIA, *contrayerva*; a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 53d order, scabridæ. There are eight species, all of them low herbaceous plants, growing in the warm countries of America and China.

DOUBLE-*cast*, in husbandry, a term used by the farmers for that method of sowing that does not dispense the necessary quantity of seed for a piece of land at one sowing, but requires going over every place twice.

DOVE-*tailing*, in carpentry, is the manner of fastening boards together by letting one piece into another, in the form of the tail of a dove. The dovetail is the strongest of jointings, because the tenon, or piece of wood which is put into the other, goes widening to the extreme, so that it cannot be drawn out again.

DOUGLASSIA, a genus of the class and order polyadelphia polyandria. There is one species, a shrub of Guiana.

DOWER, the portion which a widow has of the lands of her husband, after his decease, for the sustenance of herself, and the education of her children.

To the consummation of dower, three things are necessary, viz. marriage, seisin, and the husband's death.

DOWN, the shortest, smoothest, softest, and most delicate feathers of birds, particularly geese, ducks, and swans; growing on their neck and part of the stomach. Down is a commodity of most countries; but that in most repute for fineness, lightness, and warmth, comes from Denmark, Sweden, and other northern countries.

DRABA, a genus of the siliculosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. There are nine species; of which the only one worthy of notice is the verna, or early whitlow-grass. It has naked stalks, with leaves a little serrated. The blossoms are white, and at night the flowers hang down. It grows on old walls and dry banks. It is one of the earliest-flowering plants we have, and is good to eat as a salad.

DRACÆNA, a genus of the monogynia order, in the hexandria class of plants. There are 14 species, most of them having the habit of the palms, and one of them at least (the D. draco, which is a magnificent plant, or rather tree) affording a red powder, like the eastern dragon's blood.

DRACHM, a Grecian coin, of the value of 7½d. Drachm is also a weight used by our physicians; containing just sixty grains, three scruples, or the eighth part of an ounce.

DRACO, the dragon, in zoology, a genus belonging to the order of amphibia reptilia; the characters of which are these: it has four legs, a cylindrical tail, and two membranaceous wings, radiated like the fins of a fish, by which it is enabled to fly, but not to any great distance at a time. There are two species.

1. The volans, or flying-dragon, with the wings entirely distinct from the fore-legs. It is found in Africa and the East Indies.

2. The præpos, with the wings fixed to the fore-legs. It is a native of America. They are both harmless little creatures, and feed upon flies, ants, and small insects.

Draco *volans*, in meteorology, a fiery exhalation, frequent in marshy and cold countries. It is most common in summer; and though principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders; its appearance being that of an oblong, sometimes roundish, fiery body, with a long tail. It is entirely harmless, frequently sticking to the hands and clothes of people without injuring them in the least.

Draco, in astronomy, a constellation of the northern hemisphere, the stars in which, according to Ptolemy, are 81; according to Tycho, 82; according to Hevelius, 40; according to Bayer, 33; and according to Mr. Flamsteed, 80.

DRACOCEPHALUM, dragon's head, a genus of the gymnospermia order, in the didynamia class of plants. There are 15 species, most of them herbaceous, annual, or perennial plants, from 18 inches to three feet high, mostly with entire leaves and spikes of small monopetalous flowers, of a blue, white, or purple colour. The D. canariense is well known by the name of balm of Gilead.

DRACONTIUM, dragons, a genus of the polyandria order, in the gynandria class of plants, and in the natural method ranking under the first order, palmæ. There are five species, all natives of the Indies. The only one which makes any appearance is the pertusum, with leaves having holes, and a climbing stalk. This is a native of most of the West India islands.

DRAINING. See Agriculture.

DRAMA, a poem containing some certain

action, and representing a true picture of human life, for the delight and improvement of mankind.

The principal species of the Drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See POETRY.

DRAWBACK, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandize that has paid duty on importation.

DRAWING, in painting, is the accurate representation and just symmetry of forms and proportions; whence a painter or sculptor is said to know much or little of drawing, according to his skill in these respects; and in like manner a figure of a man or other animal, a building, or any other object represented, is said to be in drawing or out of drawing. Drawing may justly be considered as the basis of painting; for it is but labour lost, when the painter endeavours to disguise by ingenious artifices of colour, the defects of forms which are fundamentally incorrect and incoherent.

DRAWING: a representation of objects on paper, by means of chalk, lead, charcoal, crayon, or common ink, or of Indian ink, or water-colours. When the latter method is used, it is called a washed or coloured drawing. This mode has of late years been improved in a singular degree, and it is at present practised with unprecedented excellence.

DRAWING, *art of.* The art of delineating objects on the surface of any substance whatever. The fundamental part of this art is a knowledge of geometry and perspective: the study of both is therefore the first step towards the attainment of the art of drawing. See GEOMETRY and PERSPECTIVE.

The surest mode for the attainment of excellence in drawing, is to begin with such plain geometrical figures, as squares, arches, circles, ovals, cones, and cylinders, which will be useful in numerous forms of similar proportions; and having acquired sufficient facility and readiness in these figures, then to give to every object its due light and shade, according to its concavity or convexity, so as to convey the perfect idea of the elevation or depression, nearness or distance, of every part.

From this, the next step is the imitation of the forms of fruits, with their leaves; of flowers, herbs, trees of various kinds, &c.

The third step is the representation, in the same manner, of beasts, birds, fishes, &c. &c.

From this the student may proceed to the imitation of the human figure, beginning, as before remarked, with its various parts, as the eye, mouth, hand, foot, &c. &c.; and then the head, arm, leg, trunk; and lastly, the whole figure, carefully observing all its proportions. When he is sufficiently master of the naked form, let him proceed to the study of drapery, learning how to clothe a figure, so as to give it every advantage of ornament, without interruption of its air and motion, grace or symmetry.

To these acquisitions are to be added his study of architecture, landscape, and all inanimate objects, or still life.

The implements and materials most requisite for drawing are:

Drawing-boards for fixing the paper upon, so that it may not shift, and also for straining it, to prevent the colours, when laid wet upon the paper, from causing it to swell up, so as to be uneven. The simplest sort is made of a deal-board, framed square, with a strong piece across each end, to prevent warping. Upon this the paper may be fixed down with pins, or with paste, which is the better method.

The best kind of drawing-boards, however, are made with a frame and a moveable pannel, upon which the paper is simply put wet, and then forced into the frame, where it is confined by wedges at the back. This strains equally well, without the trouble of pasting, so that you may dry it at the fire; and it also looks much neater. These drawing-boards may be bought at most colour-shops. It is necessary to mention, that all the angles of drawing-boards should be exactly square.

Parallel rulers are for drawing parallel lines very readily; the best kind of parallel ruler is the rolling one, invented by Mr. Eckhardt.

T-squares are rulers made in the form of the letter T, which are used with the drawing-boards; the short end, called the stock, being applied to the edge of the board, so as to slide forwards and backwards, while the long part, called the blade, is used for drawing lines by. These are more convenient than parallel rulers, when a drawing-board is used, as by them you draw lines at right angles to each other at once, without using the compasses.

Dividing-compasses are instruments of brass and steel, for dividing lines, and laying down measures from scales, &c. They are generally sold in cases, containing also a steel pen, for drawing lines cleaner than can be done by a common pen, which is very useful where neatness is required; and points with a black-lead pencil, for putting into the compasses, when circles are to be described.

These cases also contain scales of equal parts, sectors, and protractors for laying down angles.

Black-lead pencils are indispensably necessary, and they are to be had of various degrees of hardness, and different depths of shade, according to the purpose for which they are wanted.

Indian ink. This substance comes from China, where it is used for common writing, which is there performed with a brush instead of a pen. It is a solid substance, of a brownish-black colour; and the composition is not known, but is conjectured to be the gall of a species of cuttle-fish. When ground up with water upon a clean tile or earthenware plate, it may be made either lighter or darker, as required, by adding to it more or less water. The best Indian ink is always stamped with Chinese characters, breaks with a glossy fracture, and feels smooth, and not gritty, when rubbed against the teeth. An inferior kind is made in this country, but it may be easily known by its grittiness. Sepia is now very much used in preference to Indian ink.

Hair-pencils are made of camels' hair, put into a goose or swan's quill. To choose these, moisten them a little in the mouth, and if they come to a point without splitting, they are good; if they do not, they are not fit for drawing with.

Charcoal is used for slightly sketching the outlines of figures, in order to get the propor-

tions previous to making a drawing in chalk. The best charcoal for this purpose is that of the willow; it is cut into slips, and the strokes made with it may easily be rubbed out with a feather of goose's or duck's wing.

Black-chalk is a fossil substance, resembling slaty coal, which is cut into slips for drawing. It is generally used in an instrument called a port-crayon, which is made either of steel or brass. It is much employed for drawing figures, and is the best substance for this purpose, in making drawings from plaster, or after the life. It is more gritty than black-lead, but is of a deeper black, and has not the glossiness of the former.

For mellowing and softening the shadows into each other, when black chalk is used, stumps are necessary. They are pieces of soft leather, or blue paper, rolled up quite tight, and cut to a point.

White chalk is used, together with black, for laying on the lights. This is different from common chalk, being much harder. Tobacco-pipe clay will answer the purpose.

Red chalk is a fossil substance of a red ochrey colour, which is sometimes used for drawing, but not so much now as it formerly was, the black being preferred; however, the red being cheaper, will do very well for some purposes.

Drawing-paper. Any paper that will do for writing will do for drawing; but as the wire marks in common writing-paper are injurious, paper made without any wire-marks, called wove-paper, is generally used for this purpose. It is made of various sizes and thickness.

Middle-tint paper, is paper of a brownish or of a grey colour, which is used for drawing upon with black and white chalk. Being of a dark colour, the strokes of the white chalk are distinctly seen; and it saves time in making drawings, as the tint of the paper answers for the half-shadow, so that all that is necessary to be done is to lay in the dark shadows and the lights.

We proceed to give directions for the practice of these rules, and the use of the materials which have been mentioned.

Mechanical Drawing.—In giving instructions for the study of drawing, attention must be paid to the particular branch of this art, to which the student wishes most to apply himself. If his object be the study of architecture, machinery, plans, elevations, sections, &c. then geometry will form the foundation of all his future acquirements. The study of perspective necessarily follows, and with these two sciences he must be intimately acquainted. To these he must add a thorough knowledge of the doctrine of shadows, which is best acquired by studying from models.

Having completed the outlines, Indian-ink is used for shadowing, as it may be diluted with water, so as to be of any required darkness, and may be softened off, where the objects require it, with water only and a hair-pencil. This branch of drawing we consider as a useful rather than an ornamental art. It should be learned by every person, as answering the same purposes with writing, but in a much more perfect manner, in those cases to which it is applicable. This is particularly striking in descriptions of apparatus, and machinery of every kind.

Drawing of flowers, fruits, trees, &c.—This first advance in art is so easy as to require little else than strict attention to imitate the objects placed before the eye, observing well those particularities which give the peculiar character of each, and mark the distinctness of the several species. In trees especially care is to be taken that the oak, ash, elm, &c. may each have its proper and distinct trunk, boughs, and foliage, in such a manner, that it shall be no more possible to mistake one kind of tree for another in the drawing than it is in nature. Nothing is more prejudicial to the student's progress than a habit of indiscriminate forms, which, although they denote a tree in general, do not decide its species.

Drawing of beasts, birds, fishes, &c.—In this step the student must not only study the forms of each class of the several animals, in the same manner as, in the preceding stage, he studied those of trees, but he must begin to observe the varieties of form, induced by the motions of the muscles, in all the actions of the head, body, or limbs, as well as the expression of face, characteristic action, and every other circumstance which distinguishes these from inanimate objects. In drawing beasts he will begin to find the necessity of acquiring a general knowledge of anatomy.

The student who is unacquainted with the form and construction of the several bones which support and govern the animal frame, or does not know in what mode the muscles, moving those bones, are fixed to them, can make nothing of what appears of them through the integuments with which they are covered, which appearance, however, is the object of his pencil.

Drawing the human figure.—The study of the human figure has always been considered by artists as the most important part of the art. It is the most difficult, and is by many considered as contributing the most of any to general improvement; though there are some who carry this idea to too great an extent, affirming, that a person who can draw the human figure well, can draw every thing besides. But this, it is well known, is not the case, there being many artists who can draw the figure very well, who cannot draw landscape nor architecture.

In learning to draw the human figure, it is necessary to begin with each of the parts separately, and after sufficient practice in that way, to proceed to put them together in the complete figure. For instance, the head being the most important part of the human body, it should be studied first. For this purpose, the student should copy the best drawings he can procure of the eye, mouth, nose, and ear, separately and on a large scale; and of these a front view, profile, or side view, oblique view, &c.

The false lines of the black lead may be removed by the Indian rubber; but the student must be as sparing as possible of this, as it is more improving to endeavour to draw every thing correct and decided at once.

The shadows may be laid on by drawing parallel curve-lines, according to the situation of the part, crossing them occasionally, and softening them in with more delicate lines, where necessary.

All the parts of a human figure are composed

of curved surfaces; no straight lines are ever admissible, but every line should have a graceful turn. Care should be taken that no lines ever cross each other at right angles, which gives a disagreeable net-like appearance; neither should the crossings be too oblique, as then they are confused; a proper medium will be acquired by the study of good drawings or prints. Sometimes the shadows are rubbed in with a stump, which is a very expeditious way, and produces a fine effect; but it should be used with discretion, as it is better to execute the shadows in a clear and regular manner by soft lines. Care should be taken not to make the lines harsh and hard, like those of an engraving; they should be softer and more mellow. On this account, drawings are much better to learn from than prints, as, by copying the latter, the student is very apt to acquire a dry and hard manner. But we particularly caution him to avoid copying with a pen all the lines in engravings used for the shadows, which some, who have not been accustomed to see good drawings, are apt to do.

In copper-plate engravings, there other means of producing shadows than by lines, at least with an equal effect; but this arises from the nature of the process: and in drawing, which is of a very different nature, there is not the same necessity for them. In general it should be observed, that the less labour there appears in any drawing, the better it is; and that though every possible pains should be taken to make drawings or paintings excellent, yet this labour should be always disguised as much as possible, and the whole should appear as if executed with the greatest ease.

The way to avoid mediocrity is by the study and imitation of beautiful productions, or, of the most finished translations that have been made from them; for so we may call beautiful prints. Let [illegible] aughtsman study the heads of Raffaelle, an[illegible] e will not see without disgust the sordid figures of indifferent painters.

Having copied frequently the parts of a face, he is next to proceed to the entire head, drawing first a front view, then a profile, a three-quarter, and so on, varying it in every possible direction, till he is thoroughly acquainted with the appearance of all the principal lines in every situation.

The young artist, ought, if practicable, to visit the Royal Academy, or any other public school for drawing, where he will see, at a glance, how the light should be disposed, to draw with effect; if that is impossible, he must remember to throw one light downward on the object, whether it proceeds from the day or a candle; and that he cannot too strictly attend to the true proportions of the body and limbs, as nothing is more disgusting than a want of proportion in these. To prevent his falling into such errors, let him observe, that in a well-formed person, his arms extended make a distance between the extremities of the middle fingers equal to his length; that the face consists of three exact divisions, from the hair on the forehead to the eyes, from the eyes to the bottom of the nose, and from that to the chin. The whole figure is ten faces in length; from the chin to the collar-bone is twice the length of the nose, thence to the lowest part of the breast one face, from that to the navel another, to the groin one, to the upper part of the knee two, the knee is half a face in length, from the lower part of which to the ancle is two faces, and hence to the sole of the foot is one half. Measuring from the extremes of the breast, the breadth will be found to contain two faces, and the bone of the arm from the shoulder to the elbow, the same number; thence, including part of the hand, two faces; and from the shoulder-blade to the hollow between the collar-bones, is one face. The thumb is the length of the nose; from the commencement of the hand to the middle of the arm is five lengths of the nose; and from the pectoral muscle to the same place is four. The great toe is of the length of the nose, and the sole of the foot is the sixth part of the length of the figure; the hands are double their breadth in length, and when extended they are exactly the length of the face. The breadth of the limbs varies according to the state of health in the body, and the particular situation of the muscles whenever moved.

The proportions of children are generally thus; three heads in length from the crown of the head to the groin, and thence to the sole of the foot two, one head and a half between the shoulders, one, of the body between the hips and armpits; the breadth of the limbs should be ascertained from a healthy child.

It is impossible to draw a perfectly beautiful figure from any one person: the most skilful statuaries and painters, sensible of this fact, have composed their finest works from different subjects, as it is very common for the possessor of a truly Grecian head to have a deformed trunk, or another to have graceful limbs and the face of a gorgon. To draw a figure correctly, the intended length should be marked, and all the preceding admeasurements strictly adhered to, beginning the sketch on the left hand, with the head, following by the shoulders, the trunk, the leg most in action, then the other, finishing with the arms, and making the outline perfect before any part is finished; as we may imagine a living or plaster model placed before the student, that will serve better for improving him than any written instructions, but he will find the greatest difficulty in correctly copying the eyes, mouth, ears, hands, and feet, and should consequently be particularly careful when employed on those parts to which rules are utterly inapplicable.

Drawing of Drapery.—In the art of clothing the figures, or casting the drapery elegantly upon them, many things are to be observed. 1. The shape and proportion of the part or limb, which the drapery is supposed to cover, must appear, at least so far as art and probability will permit. 2. The drapery must not sit too close to the parts of the body, but seem to flow round, as it were to embrace them, yet so as that the figure may be easy, and have a free motion. 3. The draperies which cover those parts that are exposed to great light, must not be so deeply shaded as to seem to pierce them; nor should those members be crossed by folds that are too strong, lest by the too great darkness of their shades the limbs look as if they were broken. 4. The great folds must be drawn first, and then stroked into lesser ones; and great care must be taken that they do not cross one another im-

properly. 5. Folds, in general, should be large, and as few as possible: but they must be greater or less according to the quantity and quality of the stuffs of which the drapery is supposed to be made. The quality of the persons is also to be considered in the drapery. 6. Suit the garments to the body, and make them bend with it, according as it stands in or out, straight or crooked, or as it bends one way or another; and the closer the garment fits to the body, the narrower and smaller must be the folds. 7. Folds well imagined give much spirit to any kind of action; because their motion implies a motion in the acting member. 8. An artful complication of folds in a circular manner greatly helps the foreshortenings. 9. All folds consist of two shades and no more; which you may turn with the garment at pleasure, shadowing the inner side deeper, and the outer more faintly. 10. The shades in silk and fine linen are very thick and small, requiring little folds, and a light shadow. 11. Observe the motion of the air or wind in order to draw the loose apparel all flying one way; and draw that part of the garment that adheres closest to the body before you draw the looser part that flies off from it, lest, by drawing the loose part of the garment first, you mistake the position of the figure. 12. Rich ornaments, when judiciously and sparingly used, may sometimes contribute to the beauty of draperies; but such ornaments are far below the dignity of angels or heavenly figures; the grandeur of whose draperies ought rather to consist in the boldness and nobleness of the folds, than in the quality of the stuff, or the glitter of ornaments. 13. Light and flying draperies are proper only to figures in strong motion, or in the wind: but when in a calm place, and free from violent action, their draperies should be large and flowing.

Drawing of landscapes.—Having made himself master of the principal difficulties in perspective, the artist should next copy some good drawings; and here it is of great importance that what he copies should be very excellent; for it is an absurd notion, that indifferent drawings will do to begin with, or to bring the hand in, as it is termed; but, as a great master justly observes, the most likely effect these can produce, will be to put the hand out.

In choosing drawings to copy for beginners, particular attention should be paid to select those where the outlines or forms of the objects are distinctly and correctly drawn, and not those in which a good effect only has been principally aimed at. The first thing to be studied is, to be able to express with the black-lead pencil, the forms of all sorts of objects; and till this is attained, no attempt should be made at finished drawings.

Black lead is the most useful material for drawing the outlines of landscapes, which are best executed with this alone, and should not be gone over afterwards by the pen, which generally gives an appearance of hardness.

Indian ink alone should be used for the shadows till the student has advanced very considerably; nor till then should colours of any kind be used. Beginners are always desirous of producing pictures and making coloured drawings: but nothing is more hurtful than the practising this too early. The first thing to be learned is, to draw forms correctly; next, the mode of shadowing objects truly; then the general light and shadow of a drawing, and, with this, good composition. All this is best learned by using black lead, black chalk, white chalk, Indian ink, and these separately or combined, according to the taste of the student; but he should never think of colours till he has made very considerable

he fewer colours that are used in a drawing the better, as harmony is most easily preserved, and by the mixture of a few, every possible tint may be obtained.

The best sort of water colours are those mixed with gum and made up into cakes, as these may be used by rubbing upon a tile, in the same manner as Indian ink.

GENERAL RULES.

Correctness of outline.—This is the first point to be attained, and can only be the result of patient diligence and long practice. To gain the free use of the pencil or port-crayon, let the student accustom himself to hold it farther from the point than a pen is held in writing, by which means he will have the full command and direction of it. In drawing figures in Indian ink, the use of the pencil is to draw the first sketches or outlines; as any stroke or line that is amiss, may in this be easily rubbed out; and when you have made your sketch as correct as you can with the pencil, you may then draw carefully the best outline you have got, with your crow-quill pen and ink. The ink made use of for this purpose, must be Indian ink; being much softer than the other, and not running; and by mixing it with water, it may be made to any degree of strength and used in a pen. After using the ink, you may wipe out the pencil-lines by rubbing the piece gently with the crumb of stale bread. Having thus got the outline discharged; the next thing is to shade the figures, as directed; either by drawing fine strokes with your pen, where it requires to be shaded, or by washing it with Indian ink. As to the rule and compasses, they are never or rarely to be used, except in measuring the proportion of your figures, after you have drawn them, to prove whether they are right or not; or in houses, fortifications, and other pieces of architecture.

Red lead and red or black chalk are used in the same manner as black lead. White chalk and tobacco-pipe clay are used in heightening or giving strong lights, and in drawing on coloured paper. Pastils or crayons are any colours, mixed with tobacco-pipe clay, which, while soft and in the consistency of a paste is rolled up in pieces, about the thickness of a quill, and two or three inches in length, and then dried: they are generally used on coloured paper; and the colours are rubbed and wrought one into another in such a manner that no strokes appear, but the whole looks as if done with a brush.

Of the general distribution of lights and shades.—As soon as the learner has made himself acquainted with the drawing of forms, his next endeavour must be to learn the art of disposing the light and shade of every object properly. The best rule for doing this is, to

consider from what point, and in what direction, the light falls upon the objects which he is delineating, and to let all his lights and shades be placed according to that direction throughout the whole work. It is the artful management of light and shade that gives the appearance of substance, roundness, and distance, to whatever bodies are represented by drawing. Draw a circle on a piece of paper; fill it up with any even colour, and it will appear to be a body with a round circumference and flat sides; but by colouring it stronger in the middle, and causing it gradually to weaken towards the circumference, it will receive a convex appearance like a ball or globe. In rounding the parts of any object, the extremities in turning must lose themselves insensibly, and without precipitating the light all of a sudden into the shadows, or shadows into the light, but the passage of the one into the other must be imperceptible. Objects that are painted light, must have a sufficient breadth of shadow to sustain them; and dark bodies must have a sudden light behind, to detach them from the ground, or from those objects that are placed behind them.

There should be a balance preserved between the lights and shadows: a broad light ought not to be introduced into a draught without a large shadow The nearer any object is to the eye, it is seen so much the stronger; the sight is weakened by distances, and the more remote any object is, it is seen in a more imperfect manner. Therefore, those objects which are placed foremost to the view, ought to be more finished than those that are cast behind; and they should have such a relative dominion over each other, that as one object by its heightening causes others to retire backwards, so the same object must be chased, and made to appear farther from the sight than others which are more strongly illuminated.

It is not sufficient that remote objects be only coloured in a more faint and languid manner; but, according to their distance, the parts must appear more or less confused; the eye not being able to discover minutely what is far separated from it. Pure and unmixed white either draws an object nearer, or carries it off to a greater distance. If it be accompanied with black, the opposition of light and dark renders the object more sensible, and brings it nearer to the advanced part; but pure white, being the lightest of colours, unless it be forced forwards, and supported by black, will fly off to the remotest view. As for pure black, it is the heaviest of all colours, and brings the objects nearer to the sight: it must be placed in masses, be insensibly confused, and have its proper reposes.

In the representation of bodies, give them always such lights as are most proper and convenient to their supposed situations. If the objects are in the fields or open air, and the sun not visible, or obscured by clouds, you must then introduce almost an universal light, though not warm and strong, and your shades must be faint; but when the sun is conspicuous, and shines in its full lustre, then the light must be very strong and bold, and the shadows very dark. A small light illuminating the body occasions the shadows on the dark side to be large, and their extremities to be very bold. On the other hand, a broad light makes the shadows on the darker side to be more distinct and more soft in their limitations.

Reflection is to be used in delineating glittering or shining bodies, as glass, pearls, silver, &c. Let the cause of the reflection, be it more or less, be seen in the thing itself. Place all your lights one way through the whole work; and if the light falls sideways on the picture, the other side, which is the farthest from the light, must be made the darkest. That part of the body must be made lightest which has the light most opposite to it; if the light be placed above the head, then the top of the head must be made lightest; the shoulder must receive the next greater degree of light; and thus must you continue to shade, losing the light by degrees. By how much one part of the body projects more than another, it must by so much be made the lighter: and, on the contrary, those parts that bend inwards must be made so much the darker. Two equal lights must never be made in the same picture; the greater must strike forcibly into the middle, and with greatest lustre on those parts of the design where the principal figures and strength of the action seem to lie, diminishing it gradually as it approaches nearest the extremities of the piece.

PARTICULAR DIRECTIONS.

In drawing after a picture or print, take care to place it in such a light that the gloss of the colours may not interrupt your view, but so that the light and your eye may fall equally and obliquely upon the piece. Let the piece be placed at such a distance, that you may view it all at once: and the larger the picture is, it should be placed at the greater distance: but right before you, and a little reclined.

Draw all your outlines at first very faint, that they may be easily rubbed out again. The outlines next the light should be drawn more faint; and when you have drawn one feature it should be a direction for you, in some measure, to draw another, by observing with your eye the distance from that to the next feature, making a mark at the place with your pencil, then draw it, and so on to the next, till you have drawn the whole.

Then observe the middle of the picture you would copy, and touch upon the paper with the point of your pencil; afterwards observe the more conspicuous and uppermost figures, if there are more than one, which you are to touch lightly in their proper places. Thus running over the whole draught, you will see, as it were, the skeleton of the piece you are to draw.

Having made out these sketches, view them diligently, to see if they answer your pattern or not; for the gestures of the life ought to shew themselves eminently in the first and rudest draught of the piece; correct and amend whatever you perceive amiss; adding and diminishing as it varies from the pattern.

Of drawing faces.—In drawing a head, it is usually divided into four equal parts: 1. From the crown of the head to the top of the forehead. 2. From the top of the forehead to the eyebrows. 3. From the eyebrows to the bottom of the nose. 4. From hence to the bottom of the chin. But this proportion is not con-

stant; those features, in different men, being very often different as to length and shape. In a well-proportioned face, however, they are nearly right.

Touch the features lightly, where the eyes, nose, mouth, and chin, should stand: then begin to draw them more exactly, and so proceed till you have finished the face; after which draw the hair, beard, and shadows about it. You are to consider all those chief touches which give life to a face, and that discover the disposition of the mind: thus the mouth extended, and the corners turning a little up, shews a smiling countenance, &c. You must take care that the shadows are not made too dark where they should be light, because afterwards they cannot be rendered more light.

Of drawing mixed figures.—In order to draw the form of any beast, or bird, you must be well acquainted with its shape and actions, without which you will never perform any thing well in this way; and whatever beast you draw, give a sketch of the landscape of the country natural to that beast.

In drawing birds, the feathers, beginning at the head, very small, must fall backwards one way in five ranks, still increasing till finished.

Insects, as flies, bees, wasps, grasshoppers, worms, and such-like, are drawn with great ease, provided you, for the first time, have the original before your eyes.

In drawing a flower, begin from the rose-tuft, or wart in the middle; as in a rose or marigold with the yellow tuft; which being made, draw lines equally divided from thence to the greatest compass or extent of the flower. They may be drawn either fully open, or in the bud; the leaves may be first drawn rudely, afterwards giving them their vians, or jaggedness.

Of drawing landscapes, buildings, &c—All true drawing consists in nicely measuring the distances of each part of your piece by the eye.—In order to facilitate this, you are to imagine in your mind that the piece you copy is divided into squares; as for example; suppose or imagine a perpendicular and a horizontal line crossing each other in the centre of the picture you are to copy: then suppose also two such lines crossing your own copy Observe in the original what parts of the design those lines intersect, and let them fall on the same parts of the supposed lines in your copy. If you are to draw a landscape from nature, take your station on a rising ground, where you may have a large horizon, and mark your paper into three divisions downwards, from the top to the bottom; and divide in your own mind the landscape you are to take into three divisions also. Then turn your face directly opposite to the middle of the horizontal line, and draw what is directly before your eyes upon the middle division of your paper; then turn your head, but not your body, to the left hand, and delineate what you view there joining it properly to what you had done before. Lastly, do the same by what is to be seen on your right hand, laying down every thing exactly, both with respect to distance and proportion. Make the nearest objects in your piece the highest, and those that are further off to shoot away lower and lower, till they come almost level with the line of the horizon; lessening every thing proportionably to its distance, and observing also, to make your objects fainter and less distinct the farther they are removed from your eye. Make all your lights and shades fall one way; and let every thing have its proper motion.

Transparencies, were at one time extremely fashionable, and are still used as blinds for windows, and as substitutes for painted glass. Their effect is highly pleasing when the lights are clear and brilliant, and the shades judiciously contrasted with them. In painting transparencies much depends upon the choice of the subject; and none is so admirably adapted to this species of effect as the gloomy Gothic ruin, whose antique towers and pointed turrets finely contrast their dark battlements with the pale yet brilliant moon. The effect of rays passing through the ruined windows half-choked with ivy; or of a fire among the clustering pillars and broken monuments of the choir, round which are figures of banditti, or others, whose haggard faces catch the reflecting light: these afford a peculiarity of effect not to be equalled in any other species of painting. Internal views of cathedrals also where windows of stained-glass are introduced, have a beautiful effect.

The following is the method most commonly used in painting transparencies. Fix the paper intended for this purpose in a straining frame, draw the design, and colour it in the usual manner, then placing it against a window, examine where the shades require strengthening, which will be sometimes necessary on the back of the drawing, and with the opaque substances of ivory or lamp-black, mixed with gum water; having completed it to the due effect, the brightest parts, as the moon or a fire, are to be impregnated with spirits of turpentine on each side of the paper, and the next lights on one side only; those must be covered again with a varnish, composed of two equal portions of spirits of turpentine and Canada balsam, but with great care lest it spread beyond the desired limits. The moon must not be coloured, but fire and flame will require red lead and gamboge.

There are various methods of making drawings by artificial means, such as tracing against the light of a window, using tracing paper, &c. but these, however useful they may be to the mere mechanic, should never be had recourse to by the aspiring artist, as they only tend to check his progress by cramping his genius.

The plates which accompany this article, and which are wholly confined to the drawing of the human figure, have the different articles arranged in progressive order, beginning with the simplest: and it is particularly recommended to the student that he carefully observe this order: and that he practise each figure until he can sketch it correctly, as by this method he will most effectually secure success.

DREAMS. Dreams may be defined to be those vain and transient illusions which are formed in the imagination during sleep.

Various theories have been advanced by philosophers on the subject of dreaming, but none of them can be pronounced to be perfectly satisfactory. Perhaps the reasoning of Dugald Stewart on the subject is as worthy of attention as any thing of the kind extant; but

we are persuaded that before an unobjectionable theory can be established, the functions of the brain must be better understood than at present they are.

DREIN, in military tactics, a trench made to draw the water out of a moat, which is afterwards filled with hurdles and earth, to facilitate the passage over the mud.

DRESSING *of ores*, the breaking and powdering them in the stamping mill, and afterwards washing them in a wooden trough.

DRIFT, in naval language, the angle which the line of a ship's motion makes with the nearest meridian, when she drives with her side to the wind and waves, and is not governed by the power of the helm. It also implies the distance which the ship drives on that line.

DRILL, in mechanics, a small instrument for making such holes as punches will not conveniently serve for.

Drill, or *drill-box*, a name given to an instrument for sowing land in the new method of horse-hoeing husbandry. It plants the corn in rows, makes the channels, sows the seeds in them, and covers them with earth when sown; and all this at the same time, and with great expedition. The principal parts are the seed-box, the hopper, the plough and its harrow, of all which the seed-box is the chief. It measures, or rather numbers, out the seeds which it receives from the hopper, and is for this purpose as an artificial hand; but it delivers out the seed much more equally than can be done by the hand.

DRINK, a part of our ordinary food in a liquid form, serving to dilute and moisten the dry meat.

DRIVING, in the sea language, is said of a ship when an anchor being let fall will not hold her fast, nor prevent her sailing away with the tide or wind.

DRONE, a kind of bee, larger than the common working or honey bees: it is so called from its idleness, as never going abroad to collect either honey or wax.

DROPS, in meteorology, small spherical bodies which the particles of fluids spontaneously form themselves into, when let fall from any height. This spherical figure, the Newtonian philosophers demonstrate to be the effect of corpuscular attraction.

DROPSY, in medicine, an unnatural collection of watery humours in any part of the body.

DROSERA, or *sun-dew*, a genus of the pentagynia order, in the pentandria class of plants, and in the natural method ranking under the fourteenth order, gruinales. There are nine species, two of which grow naturally in boggy places in many parts of the kingdom. They seem to receive the name of sun-dew from a very striking circumstance in their appearance. The leaves are fringed with hairs supporting small drops or globules of a pellucid liquor like dew, which continue even in the hottest part of the day and in the fullest exposure to the sun. The whole plant is acrid, and sufficiently caustic to erode the skin: but some ladies mix the juice with milk, and apply it to remove freckles. The juice that exudes from it unmixed, will destroy warts and corns.

DROWNING, signifies the extinction of life by immersion in water. In some respects there seems to be a great similarity between the death occasioned by immersion in water, and that by strangulation, suffocation by fixed air, apoplexies, epilepsies, sudden faintings, violent shocks of electricity, or even violent falls and bruises.

The following are the directions given for the recovery of drowned persons by the Royal Humane Society of London, and which, in furtherance of the benevolent object of that Society, are here inserted.

1. As soon as the patient is taken out of the water, the wet clothes, taken off with all possible expedition on the spot (unless some convenient house is very near,) and a great coat or two, or some blankets if convenient, should be wrapped round the body.

2. The body is to be carefully conveyed in the arms of three or four men, to the nearest house, where a good fire, if in the winter season, and a warm bed, can be made ready for its reception. As the body is conveying to this place, great attention is to be paid to the position of the head; it must be kept supported in a natural and easy posture, and not suffered to hang down.

3. In cold or moist weather, the patient is to be laid on a mattress or bed before the fire, but not too near, or in a moderately heated room; in warm and sultry weather, on a bed only. The body is then to be wrapped as expeditiously as possible with a blanket, and thoroughly dried with warm coarse cloths or flannels.

4. In summer or sultry weather too much air cannot be admitted. For this reason it will be necessary to set open the windows and doors.

5. Not more than six persons are to be present to apply the proper means; a greater number will be useless, and may retard, or totally prevent, the restoration of life, by rendering the air of the apartment unwholesome.

6. It will be proper for one of the assistants, with a pair of bellows of the common size, applying the pipe a little way up one nostril, to blow with some force, in order to introduce air into the lungs; at the same time the other nostril and the mouth are to be closed by another assistant, while a third person gently presses the chest with his hands, after the lungs are observed to be inflated. If the pipe of the bellows is too large, the air may be blown in at the mouth, the nostrils at the same time being closed, so that it may not escape that way.

7. Let the body be gently rubbed with flannels, sprinkled with spirits. A warming-pan heated (the body being surrounded with flannel) may be lightly moved up and down the back. Fomentations of hot brandy are to be applied to the pit of the stomach, loins, &c. and often renewed. Bottles filled with hot water, heated tiles covered with flannel, or hot bricks, may be efficaciously applied to the soles of the feet, palms of the hands, and other parts of the body. The temples may be rubbed with spirits of hartshorn, and the nostrils now and then tickled with a feather; and snuff, or eau de luce, should be occasionally applied.

8. Tobacco-fumes should be thrown up the fundament: if a fumigator is not at hand, a common pipe may answer the purpose.

The operation should be frequently performed, as it is of importance; for the good effects of this process have been experienced in a variety of instances. But should the application of tobacco-smoke in this way not be immediately convenient, or other impediments arise, clysters of this herb, or other acrid infusions with salt, &c. may be thrown up with advantage.

9. When these means have been employed a considerable time without success, and a brewhouse or warm bath can be readily obtained, the body should be carefully conveyed to such a place, and remain in the bath, or surrounded with warm grains, for three or four hours. If a child has been drowned, its body should be wiped perfectly dry, and immediately placed in bed between two healthy persons. The salutary effects of the natural vital warmth, conveyed in this manner, have been proved in a variety of cases.

10. While the various methods of treatment are employed, the body is to be shaken every ten minutes, in order to render the process of animation more successful; and children in particular, are to be much agitated, by taking hold of their legs and arms frequently and for a continuance of time.

11. If there are any signs of returning life, a spoonful of any warm liquid may be given; and if the act of swallowing can be performed, a cordial of warm brandy or wine may be given in small quantities and frequently repeated.

12. Electricity may be tried by the judicious and skilful, as its application neither prevents nor retards the various modes of recovery already recommended; but, on the other hand, will most probably tend to render the other means employed more certainly and more expeditiously efficacious.

The methods which have been described, are to be employed with vigour for three hours or upwards, although no favourable circumstances should arise; for it is a dangerous error to suppose that persons are irrecoverable because life does not soon make its appearance. Bleeding is never to be employed in such cases, unless by direction of one of the medical assistants, or some other gentleman of the faculty who has paid attention to the resuscitating art.

DRUG, a general term for goods of the druggist and grocery kinds, especially for those used in medicine and dying.

DRUGGET, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded, but usually plain.

DRUM, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or slackened at pleasure by the means of small cords and sliding knots. Some drums are made of brass, but they are commonly of wood.

There are several beats of the drum, as assembly, chamade, reveille, retreat, &c.

Drums, *kettle*, are large basons of copper or brass, rounded in the bottom, and covered with vellum or goat-skin, which is kept fast by a circle of iron, and several holes fastened to the body of the drum, and a like number of screws to screw up and down. They are much used among the horse, as also in operas, oratorios, concerts, &c.

DRUNKENNESS, a well known disorder in the brain, occasioned by drinking too freely of spiritous liquors. The crime of drunkenness is severely punished in some countries; in our own, it is still punishable by an ancient statute; but notwithstanding this, and even in defiance of the innumerable miseries that attend it, there is scarcely any vice more extensively prevalent. Indeed it may be said to be the cardinal vice of a numerous class of society; it possesses such charms, in their estimation, as to form the very bond of their union; its inspiring qualities seem necessary to fit them for the discharge of those operations on which their sustenance depends; and thus that portion of bodily labour which nature intended to subserve the prolongation of human life, is, by a most unaccountable insanity, employed in cutting short its allotted period.

DRUPA, or *druppa*, in botany, a species of pericarpium, or seed-vessel, which is succulent or pulpy, has no valve or external opening like the capsule and pod, and contains within its substance a stone or nut. The cherry, plum, peach, apricot, and all other stone-fruit are of this kind.

DRY *rot*, a disease incident to timber used for building, such as flooring-boards, joists, wainscoting, &c. Dr. Darwin is of opinion, that the dry-rot may be entirely prevented, by soaking the timber first in lime-water, till it has absorbed as much of it as possible, and, after it has become dry, immersing it in a weak solution of vitriolic acid in water, which he supposes will not only preserve it from decay for many centuries (if it be kept dry,) but also render it less inflammable; a circumstance that merits considerable attention in constructing houses.

Sir Humphrey Davy recommends a weak solution of the corrosive sublimate as the most efficient preventive of the dry rot.

DUCAT, a coin current in Germany, and other countries abroad. In Germany, Italy, and Holland, it is of the value of about 9s. 3d.; the ducat of Naples is 8s. 4d.; that of Florence or Leghorn 5s. 4d.; the gold ducat of Portugal is 6l. 15s.

DUCATOON, a silver coin likewise, frequent in several parts of Europe; its value is 5s 5d.

DUCK. See Anas.

DUCT, *ductus*, in general, denotes any tube or canal.

DUCTILITY, that property or texture of bodies, which renders it practicable to draw them out in length, while their thickness is diminished, without any actual fracture of their parts. This term is almost exclusively applied to metals.

Most authors confound the words malleability, laminability, and ductility, together, and use them in a loose indiscriminate manner; but they are very different. Malleability is the property of a body which enlarges one or two of its three dimensions, by a blow or pressure very suddenly applied. Laminability belongs to bodies extensible in dimension by a gradually applied pressure: and ductility is properly to be attributed to such bodies as can be rendered longer and thinner by drawing them through a hole of less area than the transverse section of the bodies so drawn.

DUEL, a single combat, at a time and

place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes, and Franks, that none were excused from it but women, sick people, cripples, and such as were under 21 years of age, or above 60. Even ecclesiastics, priests, and monks, were obliged to find champions to fight in their stead.

Duel, at present is used for a single combat on some private quarrel, and must be premeditated, otherwise it is called a rencounter. If a person be killed in a duel both the principals and seconds are guilty of murder, whether the seconds engage or not. It is also a very high offence to challenge a person either by word or letter, or to be the messenger of a challenge.

DUETT, in music, a composition written for two voices or instruments, with or without a bass and accompaniments.

DUKE is either the title of a sovereign prince, as the Duke of Savoy, Parma, &c. the Grand Duke of Tuscany, Muscovy, &c. or it is the title of honour and nobility next below princes.

DULCIMER, a musical instrument, strung with about fifty wires cast over a bridge at each end. It is performed upon by striking the wires with little iron rods.

DUMBNESS, the privation of the faculty of speech. The most general, or rather the sole cause of dumbness, is the want of the sense of hearing. The use of language is originally acquired by imitating articulate sounds. From this source of intelligence deaf people are entirely excluded; they cannot acquire articulate sounds by the ear: unless, therefore, articulation be communicated to them by some other medium these unhappy people must for ever be deprived of the use of language: and as language is the principal source of knowledge, whoever has the misfortune to want the sense of hearing must remain in a state little superior to that of the brute creation. Deafness has in all ages been considered as such a total obstruction to speech or written language, that an attempt to teach the deaf to speak or read was uniformly regarded as impracticable, till Dr. Wallis, and some others, proved that although deaf people cannot learn to speak or read by the direction of the ear, there are other sources of imitation by which the same effect may be produced. The organs of hearing and of speech have little or no connexion. Persons deprived of the former generally possess the latter in such perfection that nothing further is necessary, in order to make them articulate, than to teach them how to use these organs. This, indeed, is no easy task; but experience shews that it is practicable. Mr. Thomas Braidwood, late of Edinburgh, was perhaps the first who ever brought this surprising art to any degree of perfection. He began with a single pupil in 1764, and since that period has taught great numbers of people born deaf to speak distinctly, to read, to write, to understand figures, the principles of religion and morality, &c.

In the year 1810, a Society for the education of deaf and dumb children was instituted in Edinburgh. The first teacher was Mr. John Braidwood, a member of the family which has done so much for the instruction of these interesting objects. This Society is now under the superintendence of Mr. Robert Kinniburgh. The pupils are all boarded in the society's house, where they are taught reading, writing, and arithmetic; and are carefully instructed in the principles of the Christian religion. No child is admitted under nine, or above fourteen years of age; and six years are required for completing their education.

DUPLE, among mathematicians, denotes the ratio of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

Sub-**Duple ratio** is just the reverse of the former, or as 1 to 2. Such is 4 to 8, or 6 to 12.

DUPLICATE, among lawyers, denotes a copy of any deed, writing, or account. It is also used for the second letters patent, granted by the lord chancellor in a case wherein he had before done the same. Also, a second letter written and sent to the same party and purpose as a former, for fear of the first's miscarrying, is called a duplicate.

Duplicate *proportion*, or *ratio*, is a compound of two ratios: thus, the duplicate ratio of a to b, is the ratio of a^2 to b^2, or of the square of a to the square of b.

In a series of geometrical proportionals, the first term to the third is said to be in a duplicate ratio of the first to the second: thus in 2, 4, 8, 16. &c. the ratio of 2 to 8 is duplicate of that of 2 to 4, or as the square of 2 to the square of 4. Duplicate ratio is therefore the proportion of squares, as triplicate is of cubes, &c. and the ratio of 2 to 8 is said to be compounded of that of 2 to 4, and of 4 to 8.

DUPLICATION, in general, signifies the doubling of any thing, or multiplying of it by 2: also the folding of any thing back again on itself.

DUPLICATURE, among anatomists, a term used to denote the folds of any membrane, or vessel: thus we say, the duplicatures of the intestines, peritonæum, &c. See Anatomy.

DUPONDIUS, in antiquity, the weight of two pounds; also a piece of money equal to two ases in value.

DURA *mater*, in anatomy, one of the membranes, which surround the brain.

DURATE′, in music, a term properly applicable to whatever offends the ear by its effect. The B natural, on account of its hardness, was formerly called B durate.

DURANTA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There are three species shrubs of South America.

DURESS, in law, is where a man is kept in prison, or restrained of his liberty, contrary to the order of law.

DURIO, a genus of the class and order polyadelphia polyandria. The calyx is five-cleft; corolla five-petalled: style one; stamina in five bodies; pome five-celled. There is one species, a tree of the East Indies.

DUROIA, in botany, a genus of the monogynia order, belonging to the hexandria class

of plants. There is one species, a tree of Surinam.

DUTY, in policy and commerce, signifies the impost laid on merchandizes at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp-duties, &c.

DWARF, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds; thus there are dwarfs of the human species, dwarf-dogs, dwarf-trees, &c.

DYEING. The art of dyeing consists in fixing upon cloths of various kinds any colour which may be required, in such a manner that they shall not be easily altered by those agents to which the cloth will most probably be exposed.

As there can be no cause by which any colouring matter can adhere to any cloth, except an attraction subsisting between the two substances, it must follow, that there will be few tinging matters capable of indelibly or strongly attaching themselves by simple application. Dyeing is therefore a chemical art.

The most remarkable general fact in the art of dyeing, consists in the different degrees of facility, with which animal and vegetable substances attract and retain colouring matter, or rather the degree of facility with which the dyer finds he can tinge them with any intended colour. The chief materials of stuff to be dyed are wool, silk, cotton, and linen, of which the former two are more easily dyed than the latter. This has been usually attributed to their greater attraction to the tinging matter.

Wool is naturally so much disposed to combine with colouring matter, that it requires but little preparation for the immediate processes of dyeing; nothing more being required than to cleanse it, by scouring, from a fatty substance, called the yolk, which is contained in the fleece. For this purpose an alkaline liquor is necessary; but as alkalis injure the texture of the wool, a very weak solution may be used. For if more alkali were present than is sufficient to convert the yolk into soap, it would attack the wool itself. Putrid urine is therefore generally used, as being cheap, and containing a volatile alkali, which, uniting with the grease, renders its soluble in water.

Silk, when taken from the cocoon, is covered with a kind of varnish, which, because it does not easily yield either to water or alcohol, is usually said to be soluble in neither. It is therefore usual to boil the silk with an alkali, to disengage this matter. Much care is necessary in this operation, because the silk itself is easily corroded or discoloured. Fine soap is commonly used, but even this is said to be detrimental; and the white China silk, which is supposed to be prepared without soap, has a lustre superior to that of Europe. Silk loses about one-fourth of its weight by being deprived of its varnish. See BLEACHING.

The intention of the previous preparations seems to be of two kinds. The first, to render the stuff or material to be dyed as clear as possible, in order that the aqueous fluid to be afterwards applied may be imbibed, and its contents adhere to the minute internal surfaces. The second is, that the stuff may be rendered whiter and more capable of reflecting the light, and consequently enabling the colouring matter to exhibit more brilliant tints.

Some of the preparations, however, though considered merely as preparative, do really constitute part of the dyeing processes themselves. In many instances a material is applied to the stuff, to which it adheres: and when another suitable material is applied, the result is some colour desired. Thus we might dye a piece of cotton black, by immersing it in ink; but the colour would be neither good nor durable, because the particles of precipitated matter, formed of the oxide of iron and acid of galls, are already concreted in masses too gross either to enter the cotton, or to adhere to it with any considerable degree of strength. But if the cotton be soaked in an infusion of galls, then dried, and afterward immersed in a solution of sulphate of iron, (or other ferruginous salt,) the acid of galls being every where diffused through the body of the cotton, will receive the particles of oxide of iron, at the very instant of their transition from the fluid, or dissolved to the precipitated or solid state; by which means a perfect covering of the black inky matter will be applied in close contact with the surface of the most minute fibres of the cotton. This dye will therefore not only be more intense, but likewise more adherent and durable.

The French dyers, and after them the English, have given the name of *mordant* to those substances which are previously applied to piece goods, in order that they may afterward take a required tinge or dye.

It is evident, that if the mordant be universally applied over the whole of a piece of goods, and this be afterward immersed in the dye, it will receive a tinge over all its surface; but if it be applied only in parts, the dye will strike in those parts only. The former process constitutes the art of dyeing, properly so called; and the latter, the art of printing woollens, cottons, or linens, called calico-printing.

In the art of printing piece goods, the mordant is usually mixed with gum or starch, and applied by means of blocks or wooden engravings in relief, or from copper plates, and the colours are brought out by immersion in vessels filled with suitable compositions. Dyers call the latter fluid the bath. The art of printing affords many processes, in which the effect of mordants, both simple and compound, is exhibited. The following is taken from Berthollet.

The mordant employed for linens, intended to receive different shades of red, is prepared by dissolving in eight pounds of hot water, three pounds of alum, and one pound of acetate of lead, in which two ounces of potash, and afterward two ounces of powdered chalk, are added.

In this mixture, the sulphuric acid combines with the lead of the acetate and falls down, because insoluble, while the argillaceous earth of the alum unites with the acetic acid disengaged from the acetate of lead. The mordant therefore consists of an argillaceous acetic salt, and the small quantities of alkali and chalk serve to neutralize any disengaged acid which might be contained in the liquid.

Several advantages are obtained by thus changing the acid of the alum. First, the argillaceous earth is more easily disengaged from the acetic acid, in the subsequent processes, than it would have been from the sulphuric. Secondly, this weak acid does less harm when it comes to be disengaged by depriving it of its earth. And thirdly, the acetate of alumina not being crystallizable like the sulphate, does not separate or curdle by drying on the face of the blocks for printing, when it is mixed with gum or starch.

When the design has been impressed by transferring the mordant from the face of the wooden blocks to the cloth, it is then put into a bath of madder, with proper attention that the whole shall be equally exposed to this fluid. Here the piece becomes of a red colour, but deeper in those places where the mordant was applied. For some of the argillaceous earth had before quitted the acetic acid, to combine with the cloth; and this serves as an intermedium to fix the colouring matter of the madder, in the same manner as the acid of galls, in the former instance, fixed the particles of oxide of iron. With the piece in this state, the calico-printer has only therefore to avail himself of the difference between a fixed and a fugitive colour. He therefore boils the piece with bran, and spreads it on the grass. The fecula of the bran takes up part of the colour, and the action of the sun and air renders more of it combinable with the same substance.

In other cases the elective attraction of the stuff to be dyed has a more marked agency. A very common mordant for woollens is made by dissolving alum and tartar together; neither of which is decomposed, but may be recovered by crystallization upon evaporating the liquor. Wool is found to be capable of decomposing a solution of alum, and combining with its earth; but it seems as if the presence of disengaged sulphuric acid served to injure the wool which is rendered harsh by this method of treatment, though cottons and linens are not, which have less attraction for the earth. Wool also decomposes the alum, in a mixture of alum and tartar; but in this case there can be no disengagement of sulphuric acid, as it is immediately neutralized by the alkali of the tartar.

Metallic oxides have so great an attraction for many colouring substances, that they quit the acids in which they were dissolved, and are precipitated in combination with them. These oxides are also found by experiment to be strongly disposed to combine with animal substances; whence in many instances they serve as mordants, or the medium of union between the colouring particles and animal bodies.

The colours which the compounds of metallic oxides and colouring particles assume, then, are the product of the colour peculiar to the colouring particles, and of that peculiar to the metallic oxide.

The following are the dye-stuffs used by the calico-printers for producing fast colours. The mordants are thickened with gum, or calcined starch, and applied with the block, roller, plates, or pencil.

1. *Black.* The cloth is impregnated with acetate of iron (iron liquor,) and dyed in a bath of madder and logwood.

2. *Purple.* The preceding mordant of iron, diluted; with the same dying bath.

3. *Crimson.* The mordant for purple, united with a portion of acetate of alumina, or red mordant, and the above bath.

4. *Red.* Acetate of alumina is the mordant, (see ALUMINA,) and madder is the dye-stuff.

Pale red of different shades. The preceding mordant diluted with water, and a weak madder bath.

6. *Brown* or *Pompadour.* A mixed mordant, containing a somewhat larger proportion of the red than of the black; and the dye of madder.

7. *Orange.* The red mordant; and a bath first of madder, and then of quercitron.

8. *Yellow.* A strong red mordant; and the quercitron bath, whose temperature should be considerably under the boiling point of water.

9. *Blue.* Indigo, rendered soluble and greenish-yellow coloured, by potash and orpiment. It recovers its blue colour by exposure to air, and thereby also fixes firmly on the cloth. An indigo vat is also made, with that blue substance diffused in water with quicklime and copperas. These substances are supposed to deoxidize indigo, and at the same time to render it soluble.

Golden-dye. The cloth is immersed alternately in a solution of copperas and lime water. The protoxide of iron precipitated on the fibre, soon passes, by absorption of atmospherical oxygen, into the golden-coloured deutoxide.

Buff. The preceding substances, in a more dilute state.

Blue vat, in which white spots are left on blue ground of cloth, is made by applying to these points a paste composed of a solution of sulphate of copper and pipe-clay; and after they are dried, immersing it stretched on frames, for a definite number of minutes, in the yellowish-green vat, of one part of indigo, two of copperas, and two of lime, with water.

Green cloth dyed blue and well washed, is imbued with the aluminous acetate, dried and subjected to the quercitron bath.

In the above cases the cloth, after receiving the mordant paste, is dried, and put through a mixture of cow dung and warm water. It is then put into the dyeing vat or copper.

Fugitive Colours.

All the above colours are given by making decoctions of the different colouring woods; and receive the slight degree of fixity they possess, as well as great brilliancy, in consequence of their combination or admixture with the nitro muriate of tin.

1. *Red* is frequently made from Brazil and peach wood.

2. *Black.* A strong extract of galls and deuto-nitrate of iron.

3. *Purple.* Extract of logwood and the deuto-nitrate.

4. *Yellow.* Extract of quercitron bark, or French berries, and the tin solution.

5. *Blue.* Prussian blue and solution of tin.

Fugitive colours are thickened with gum tragacanth, which leaves the cloth in a softer

state than gum-senegal; the goods being sometimes sent to market without being washed. For farther information the reader is referred to the excellent treatise on dyeing by Berthollet, edited by Dr. Ure, from whose Dictionary of Chemistry the above article is copied.

DYNASTY, among ancient historians, signifies a race or succession of kings of the same line or family: such were the dynasties of Egypt. The Egyptians reckon thirty dynasties within the space of 36,525 years; but the generality of chronologers look upon them as fabulous. And it is very certain that these dynasties are not continually successive, but collateral.

DYSENTERY. See MEDICINE.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach.

DYSPEPSY, a difficulty of digestion, for which physicians prescribe bitters.

DYSPNOEA, a difficulty of breathing, usually called asthma.

DYSURY, in medicine, a difficulty of making urine, attended with a sensation of heat and pain. It is distinguished from a stranguary, as in the last, the urine is voided by only a drop, as it were, at a time, but, however, with pain; and from an ischury, as in this disorder, there is an almost total suppression of urine.

DYTISCUS, *the water-beetle*, in zoology, a genus of insects of the order of coleoptera. There are 23 species, distinguished by their antennæ, the various colours of the elytra, &c. The larvæ are often met with in water. They are oblong, and have six scaly feet. The body consists of eleven segments. The head is large, with four filiform antennæ, and a strong pair of jaws. The last segments of the body have rows of hairs on the sides; and the abdomen is terminated by two spines. The larvæ are frequently of a greenish variegated brown; they are lively, and extremely voracious: devouring other water-insects, and even each other. The perfect insect is little inferior to its larvæ in voraciousness, but it can only exercise its cruelty on the larvæ; the perfect insects, like himself, being sheltered by a scaly cuirass. This creature must be touched cautiously: for, besides its power of giving a severe gripe with its jaws, it has a long sharp spine, which it drives into the fingers. The eggs of the dytisci are large, and inclosed in a silky duskish cod.

The perfect insects are common in stagnated waters which they quit in the evening to fly about. They swim with great agility, making use of their hinder legs as oars.

E.

E, The fifth letter of the alphabet, and second vowel, has different pronunciations in most languages. The Greeks have their eta η, and epsilon ε, or long and short e. The French have their *e* open pronounced much like our *a*, in the words *face* and *make;* their *e* masculine, pronounced not unlike our *y* at the end of words, as *libertee, liberty;* their *e* feminine, or mute, and their *e* before an *m* or *n*, which sounds like our *a* in the word *war:* these are all exemplified in the words *empechee* or *enfermee.* In English there are three kinds of *e, viz.* the open or long *e*, as in the words *bear, wear;* the close or short *e*, as in *wet, kept*; and mute *e*, which serves to lengthen the syllable, as in *love, came,* &c.

As a numeral, E stands for 250. In music it denotes the tone *e-la-mi.* In the calendar it is the fifth of the dominical letters. And in sea-charts it distinguishes all the easterly points; thus E. alone denotes, E. by S. and E. by N. east by south, and east by north.

EAGLE. See FALCO.

EAGLE, in astronomy. See AQUILA.

EAGLE, in heraldry, is accounted one of the most noble bearings. They are generally borne with their wings and tails expanded. This posture is best fitted to fill up the escutcheon.

EAR, in anatomy, the organ of hearing. See ANATOMY.

EAR, in music, implies, that sensible, clear, and true perception of musical sounds, by which we are offended at dissonance, and pleased with harmony. To have an ear, which is a common phrase is to be capable of distinguishing the true intonation from the false, to be sensible of metrical precision, and to feel all the nicer changes of artificial combination.

EAR-*wig.* See FORFICULA.

EARING, in the sea-language, is that part of the bolt-rope which, at the four corners of the sail, is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard arms, and thus the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are seized or bent at the clew.

EARL, a British title of nobility, next below a marquis, and above a viscount. Earls were anciently called *comites,* because they were wont *comitari regem,* to wait upon the king for council and advice.

EARTH. See ASTRONOMY and GEOLOGY.

EARTHQUAKE. See PHYSICAL GEOGRAPHY.

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection.

In the primitive ages of the church, there were very great disputes about the particular time when this festival was to be kept. The Asiatic churches kept their Easter upon the very same day the Jews observed their passover; and others, on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that Easter should be kept upon one and the same day, which should always be a Sunday, in all Christian churches throughout the world.

EAU *de luce*, a fragrant liquor, possessing and retaining a milky opacity, made chiefly of mastic dissolved in alcohol, to which are added, elemi and aqua ammoniæ puræ.

EBENUS, the ebony-tree, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The segments of the calyx are the length of the corolla, and the latter has scarcely any alæ. There is one rough seed. There are two species.

The cretica is a native of the island of Crete, and some others in the Archipelago. It rises with a shrubby stalk, three or four feet high, which puts out several side branches with hoary leaves at each joint, composed of five narrow spear-shaped lobes, which join at their tails to the foot-stalk, and spread out like the fingers of a hand. The branches are terminated by thick spikes of purple flowers.

The pinnata is a biennial, a native of the Levant. These plants constitute the genus ebenus of botanists; but there is reason to think that the wood of this name is produced from several different trees.

ECHENEIS, the remora, in ichthyology, a genus belonging to the order of thoracici. The head is fat, naked, depressed, and marked with a number of transverse ridges; it has ten rays in the branchiostege membrane; and the body is naked. There are two species, viz.

1. The remora or sucking-fish, with a forked tail, and 18 striæ on the head. It is found in the Indian Ocean.

2. The neucrates, with an undivided tail, and 16 striæ on the head. It is likewise a native of the Indian Ocean.

These fishes are often found adhering so strongly to the sides of sharks and other great fish, by means of the structure of the head, as to be got off with difficulty.

ECHINOPHORA, in botany, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. There are two species, herbaceous plants of the south of Europe.

ECHINOPS, a genus of the polygamia segregatæ order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are five species, annual and perennial plants, one of which is well known under the name of globe thistle.

ECHINORYNCHUS, a genus of the vermes intestina; body round, proboscis cylindrical, retractile, and crowned with hooked prickles. They are found fixed firmly to the viscera of various animals, generally the intestines. There are 48 species.

ECHINUS, in zoology, the sea hedgehog, a genus of insects belonging to the order of vermes mollusca. The species are, 1. The esculentus, or eatable echinus, is of an hemispherical form, covered with sharp spines, commonly of a violet colour; moveable; adherent to small tubercles. These are their instruments of motion by which they change their place. This species is taken in dredging, and often lodges in cavities of rocks. 2. The lacunosus, is of an oval depressed form; on the top it is of a purple colour, the lower side studded, and divided by two smooth spaces; length, four inches. It is covered with bristles. There are 15 other species.

ECHITES, in botany, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 30th order, contortæ. There are 22 species, shrubs, chiefly of South America.

ECHIUM, *viper's bugloss*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. There are 21 species, three of which are natives of Britain. None of them have any remarkable property, except that the flowers of one species (the vulgare) are very grateful to bees.

ECHO, a sound reflected, or reverberated from some body, and thence returned or repeated to the ear.

For an echo to be heard, the ear must be in the line of reflection; that the person who made the sound may hear the echo, it is necessary he should be in a perpendicular line to the place which reflects it. Those murmurs in the air, that are occasioned by the discharge of great guns, &c. are a kind of indefinite echoes, and are produced from the vaporous particles suspended in the atmosphere, which resist the undulations of sound, and reverberate them to the ear.

There can be no echo, unless the direct and reflex sounds follow one another at a sufficient distance of time; for if the reflex sound arrives at the ear before the impression of the direct sound ceases, the sound will not be doubled, but only rendered more intense.

Echoing bodies may be so contrived and placed, that reflecting the sound from one to the other, a multiple echo, or many echoes, shall arise. At Rosneath, near Glasgow, in Scotland, there is an echo that repeats a tune played with a trumpet three times completely and distinctly. At the sepulchre of Metella, wife of Crassus, there was an echo, which repeated what a man said five times. Authors mention a tower at Cyzicus, where the echo repeated seven times. There is an echo at Brussels that answers fifteen times.

One of the finest echoes we read of is that mentioned by Barthius, in his notes on Statius's Thebais, lib. vi. ver. 30, which repeated the words a man uttered 17 times. This was on the banks of the Naha, between Coblentz and Bingen.

Echo, in architecture, a term applied to certain kinds of vaults and arches, most commonly of elliptical and parabolical figures, used to redouble sounds, and produce artificial echoes.

Echo, in poetry, a kind of composition wherein the last words or syllables of each verse contain some meaning, which being repeated apart, answers to some question or other matter contained in the verse, as in this beautiful one from Virgil:

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

ECHOMETER, among musicians, a kind of scale or rule, with several lines thereon, serving to measure the duration and length of sounds, and to find their intervals and ratios.

ECLECTICS, ancient philosophers, who, without attaching themselves to any particular sect, selected whatever appeared to them the best and most rational, from each.

ECLIPSE, the deprivation of the light of

the sun, or of some heavenly body, by the interposition of another heavenly body between our sight and it. See Astronomy.

ECLIPTA, a genus of the class and order syngenesia polygamia superflua. The recept. is chaffy down none; corollets of the disk four-cleft. There are five species, herbaceous plants of the East and West Indies.

ECLIPTIC, in astronomy, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about 23° 30′, which is the sun's greatest declination; or, more strictly speaking, it is that path or way among the fixed stars that the earth appears to describe to an eye placed in the sun.

Ecliptic, *obliquity of*, is the angle which its plane makes with that of the equinoctial. The inclination of the equator to the ecliptic is measured by the arch of a great circle intercepted between their poles, which was taken with very great accuracy by Dr. Maskelyne, in the year 1769, and found to be 23° 28′ 10″, or 23° .46944. It was formerly found by Dr. Bradley to be 23° 28′ 30″, who supposed that there was a gradual approach of the ecliptic to the equinoctial at the rate of 1′ in 100 years. The mean obliquity of the ecliptic is augmented by 9″, when the moon's ascending node is in the vernal equinox. It is on the contrary, diminished 9″, when the node is in the autumnal equinox, and it is equal to the mean when the node is in the colure of the solstices. This change of the inclination of the earth's axis to the plane of the ecliptic was called the nutation of the axis by Sir Isaac Newton.

Ecliptic, in geography, a great circle on the terrestrial globe, not only answering to, but falling within the plane of the celestial ecliptic. See Globe.

ECLOGUE, in poetry, a kind of pastoral composition, or a small elegant poem, in a natural simple style. See Poetry.

ECONOMY, *political*. Political economy is the science which treats of the wealth of nations. Its object is to ascertain, in the first place, wherein wealth consists, and then to explain the causes of its production, and the principles on which it is distributed through the different orders of society. It likewise endeavours to point out the tendency which any political regulations may have to favour or to injure the productions or most advantageous distribution of wealth. Such is its peculiar object, and consequently though writers on political economy may frequently treat on the more important topics of national security, freedom and happiness, these are then passing the strict limits of their science.

Political economy, in some of its branches, has engaged the attention of speculative men in all ages; but it is only in very recent times that the truths it exhibits have been collected, arranged, and demonstrated with such precision, as to entitle it to the name and dignity of a science.

The greatest writer that has yet appeared on this subject is Dr. Adam Smith, whose well known work on the Wealth of Nations has raised him to the high rank among politicians which Sir Isaac Newton holds among astronomers.

EFFERVESCENCE is the commotion produced in fluids by some part of the mass suddenly taking the elastic form, and escaping in numerous bubbles.

EFFLORESCENCE is the effect which takes place when bodies spontaneously become converted into a dry powder. It is almost always occasioned by the loss of the water of crystallization in saline bodies.

EFFLUVIUM, in physiology, a term much used by philosophers and physicians, to express the minute particles which exhale from most, if not all, terrestrial bodies in form of insensible vapours. Sometimes, indeed, these effluvia become visible, and are seen ascending in form of smoke; constituting what, in animals and plants, makes the matter of perspiration.

EGGS. The eggs of hens, and of birds in general, are composed of several distinct substances. 1. The shell or external coating, which is composed of carbonate of lime .72, phosphate of lime .2, gelatine .3. The remaining .23 are perhaps water. 2. A thin white and strong membrane, possessing the usual characters of animal substances. 3. The white of the egg, for which see Albumen. 4. The yolk, which appears to consist of an oil of the nature of fat oils, united with a portion of serous matter, sufficient to render it diffusible in cold water, in the form of an emulsion, and concrescible by heat. Yolk of egg is used as the medium for rendering resins and oils diffusible in water.

EHRETIA, in botany, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. There are five species, trees and shrubs of the West Indies.

EHRHARTA, a genus of the monogynia order, in the hexandria class of plants. There are five species; grasses of the Cape.

EJECTMENT. An ejectment is a mixed action, by which a lessee for years, when ousted, may recover his term and damages; it is real in respect of the lands, but personal in respect of the damages.

EKEBERGIA, a genus of the class and order decandria monogynia. The calyx is four-parted; petals four; berry contains five oblong seeds. There is one species, a tree of the Cape.

ELÆAGNUS, *oleaster*, or *wild olive*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 16th order, calycifloræ There are nine species. The most remarkable are, 1. orientalis, or eastern broad-leaved olive, with a large fruit, is a native of the Levant, and some parts of Germany. 2. The angustifolia, without thorns, is that kind commonly preserved in the gardens of this country. The leaves are more than three inches long, and have a shining appearance like satin. The flowers come out at the footstalks of the leaves, sometimes singly, at other times two, and sometimes three, at the same place. The outside of the empalement is silvery and studded; the inside of a pale yellow, and having a very strong scent. 3. The latifolia, with oval leaves, is a native of Ceylon, and some other parts of India.

ELÆIS, a genus belonging to the natural order of palmæ. There is one species, from the fruit of which, the negroes extract the famous palm oil.

ELÆOCARPUS, a genus of the monogynia

order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. There are six species, trees of the East Indies. One of them, the copaliferus, yields the resin so useful as a varnish, called gum copal.

ELÆODENDRUM, olive wood, a genus of the pentandria monogynia class and order. There are two species, trees of Africa.

ELASTICITY, or *elastic force*, that property of bodies with which they restore themselves to their former figure, after any external pressure; being the same with what is called springiness.

Elasticity is increased by augmenting the density of a body: thus metals are rendered more elastic by being beaten by a hammer. Steel is more elastic when tempered, and its density is increased in the ratio of 7809 to 7738.

Elasticity is sometimes increased by cold; thus the range of a cannon-ball is said to be greater when the cannon is cold, than when heated; and the string of a violin is inflected, and recovers its situation, with less force in hot than in cold weather.

Metal fibres, and thin steel laminæ, exhibit no elasticity, unless stretched to a certain degree, and inflected by a certain force; as appears from lax cords, which, if a little stretched and removed from their natural state, discover no tendency to return to it; and when the inflection of a fibre is very great, the influence of elasticity seems to be in some cases annihilated, as appears by the fibres of wood, which, inflected to a certain degree, remain quiescent, and have no tendency to recover their former situation. The limits where the elastic power begins, or where it terminates, are unknown.

ELATE, a genus belonging to the natural order of palmæ. There is one species, a native of the East Indies, which grows to the height of 14 feet. The natives chew the nut in the same manner as the leaf of the betel.

ELATER, in zoology, a genus of insects, belonging to the order of coleoptera. By means of a spring under the thorax, the animal, when turned upon its back, contrives to leap up into the air, and so turn itself. In the state of larvæ it inhabits the trunks of decayed trees, and is there transformed.

ELATERIUM, a genus of the monandria order, in the monœcia class of plants; and in the natural method ranking under the 34th order, cucurbitaceæ. There are two species, natives of America.

ELATINE, a genus of the tetragynia order, in the octandria class of plants; and in the natural method ranking under the 15th order, inundatæ. There are two species, annual aquatics of Europe.

ELECTION, is where a person has by law two remedies, and is compelled to declare which he will abide by: thus a creditor, in cases of bankruptcy, may either prove his debt under the commission, or proceed at law; but in this case he is compelled to make his election.

Election *of members of parliament*. Qualification of the candidates. No member shall sit or vote in either house of parliament unless he be 21 years of age. 4 Inst. 47.

They must not be aliens-born; they must not be any of the twelve judges because they sit in the house of lords. But persons who have judicial places in the other courts, ecclesiastical or civil, are eligible. Nor of the clergy; the reason assigned for which is, that they might sit in the convocation. Nor persons attainted of treason or felony, for they are unfit to sit any where.

ELECTIVE *attraction*. See Attraction and Chemistry.

ELECTRICITY. This term which is derived from the word *electron*, the Greek name of amber, is now generally applied to that science which investigates the attractions and repulsions, the emission of light, and explosions, which are produced, not only by the friction of vitreous, resinous, and metallic surfaces, but by the heating, cooling, evaporation, and mutual contact of a vast number of bodies.

It is common for writers on the subject of electricity to give at least a sketch of the history of the science; but as we are necessarily compelled to study the utmost brevity in a work like the present, we must be excused entering on such a detail; simply remarking, that the electrical phenomena constitute the first physical fact recorded in the history of science.

Neither shall we here attempt a discussion on the nature of the electric substance; since, at the present hour, the most rational theories before the public are at least but hypothetical; although it must be allowed, that the means of investigation which are now at the command of scientific men; the persevering diligence with which those means are employed; and the success which seems to crown their labours, unite in announcing the near approach of some discovery that will effect what has baffled the ingenuity of philosophers for nearly two thousand years.

The first thing that demands attention on this subject is the proper management of the electrical machine. Although it must require considerable practice to enable a person to perform electrical experiments with neatness and success, yet the path to this very desirable end may, we conceive, be much shortened by a strict attention to suitable directions.

OF ELECTRICAL MACHINES.

There are two forms of the electrical machine, viz. the cylindrical, which is the most common, and the cheapest form in which the machine can be made; and the plate machine, which has decidedly the advantage of the cylindrical in point of elegance, and also in power, although some prefer the latter on account of the facility which it affords for producing negative electricity.

Fig. 1. Plate XIV. represents the cylindrical machine in the simplest and most convenient form, in which it can be constructed. A A A A is the board on which the supporters and pillars are erected, and by which the machine is made fast with cramps to the table. B B B B are two wooden pillars or supporters having their lower ends mortised into the board A A A A, and in the upper ends of these the axis of the glass cylinder C C C C turns. D D is the winch by which the cylinder is turned on its axis. E E is a piece of wood, a part of which slides into a grove under the board A A A A, and is made fast by the

thumb-screw *f*. G G is a glass pillar, which is fixed to the wood E E, and supports what is called the negative conductor and rubber H H. I I is another piece of wood, which slides in a similar groove under the board A A A A, and is made fast by the thumb-screw *j*. K K is a glass pillar fixed into the wood I I, and supports the prime conductor L L; to this conductor a number of metallic points are attached, to collect the fluid from the surface of the cylinder, and lead it to the prime conductor. M M is a rod of brass inserted in the prime conductor, having a joint by which it may be raised or lowered, to suit the height of the apparatus; this rod is a most useful appendage to the prime conductor. To the upper part of the rubber a piece of black silk is attached, which proceeds from thence over the top of the cylinder, to within about half an inch of the points of the wires inserted in the prime conductor; by which means the fluid that is brought into action by the attrition of the cylinder and rubber is prevented from being dissipated in the air, and carried round with the cylinder to the prime conductor. The action of the silk on the cylinder tends very much to increase the excitation of the machine, as may be seen by removing the cushion a little back from the cylinder, and leaving the silk to act upon it alone, in which case the excitation will often be found to be scarcely less than when the rubber is also in contact with the cylinder.

The plate electrical machine, represented fig. 2. Plate XIV, was invented by Dr. Ingenhouz, and has been perfected by Mr. Cuthbertson. It consists of a circular plate of glass, turning on an axis which passes through its centre; it is rubbed by two pairs of cushions fixed at opposite points of its periphery by elastic frames of thin mahogany, which are made to press the glass-plate with the required degree of force, by means of regulating screws. A brass conductor, supported by glass, is fixed to the frame of the machine, with its branched extremities opposite each other, and near the extreme diameter of the plate, in a direction at right angles with the vertical line of the opposite cushions. The branched extremities of the conductor are furnished with pointed wires, which serve to collect the electricity from the surface of the excited plate. These machines are sometimes fitted up with two plates, which are fixed on the same axis, by which the power of two machines is combined in one, although the labour of turning such a machine is thereby augmented considerably; where a copious flow of electricity is required, two of these double plate machines may be used, or a single plate of large diameter. The motion of the machine must always be in the direction of the silk flaps that proceed from the rubbers.

The cylindrical machine however being at present in more common use than the plate machine, it is hoped the following remarks may be of use to those who possess such an instrument, and particularly to such as may be disposed to provide themselves with it for the sake of economy. A cylindrical electrical machine ought never to be less than ten inches in diameter; there are cylinders of six, seven, eight, and nine inches diameter, often neatly mounted, and sold by the philosophical instrument makers, but they are of no manner of use for the purpose of experiment, and serve only as a kind of philosophical toy, for the amusement of children, and that too on a very narrow scale. To construct such machines, therefore, is an absolute waste of the materials. With a cylinder of ten inches, properly managed, a tolerable exhibition may be made, but the most convenient size is from twelve to sixteen, the length of the cylinder being in proportion.

The most powerful excitation of the machine is produced as follows. Let the machine be placed within the influence of a good fire, but not so near as to injure any of its parts by the action of the heat. With a flat round pointed knife spread a little amalgam evenly along the cushion, and return it to its place: turn the cylinder a few times round; then take off the cushion, and observe carefully those parts on its surface that have not been touched by the cylinder while revolving; on these parts put a little more amalgam, and repeat the process of turning the cylinder, and supplying the defective parts with amalgam, till every point of that part of the surface of the cushion which presses on the cylinder appears to be properly supplied with amalgam. Take now a piece of leather about five or six inches square, and spread over one side of it a quantity of amalgam; throw back the silk flap, and, turning the machine gently round, apply the amalgamed side of the leather to the cylinder, for the space of two minutes or more, as circumstances may require, during which time the excitation will be observed to increase rapidly. The cylinder must next be wiped perfectly clean with an old silk handkerchief, and afterwards with a soft dry linen cloth. Let the cushion be again removed; and the amalgam which appears above and below the line of contact with the cylinder carefully scraped off, the silk flap wiped, with the linen cloth, and the whole returned to its place and made fast. If now the cylinder be turned slowly round, streams of the electric fluid will be seen rushing from the silk flap round the lower part of the cylinder, attended with a hissing and snapping noise, while large brushes of the same, of several inches in length may be observed flying off from the lower edge of the silk into the surrounding air. The machine is now fit for use, and may be fastened to the table, after which the whole of its parts are to be well wiped with a warm and dry linen cloth to free them from dust.

The operator however must not expect this high and rich state of excitation to be of long duration. The cylinder will soon cool; dust will be attracted by the action of the machine; and the moisture produced in the air of the room by the breaths of his audience, will, by their united effects render all his efforts to produce a copious supply of electricity entirely fruitless.

To remedy this defect, which gentlemen who deliver public lectures on electricity have often found to be a grievous one, provide a box of thin plate iron, ten or twelve inches long, four inches wide, and one inch and a half in depth, with a lid to fit very easily over it. In this box a piece of bar iron of about six inches in length, three in breadth, and half an inch in thickness, after being heated in the fire to a dull red heat is to be placed, the lid of the box

put on, and the whole, on a suitable iron stand, placed under the cylinder, on the board of the machine in a longitudinal direction. The radiation of heat from the iron will effectually preserve the equality of the temperature of the surrounding air for a considerable length of time, and indeed, for any length of time required, since, by employing two bars of iron, the one may be kept in the fire while the other is in the box, and thus no other interruption in the course of the experiments will be necessary beyond what is occasioned by the changing of the irons. By this means the machine may be made to act in full vigour under the most disadvantageous circumstances. Whilst writing this article we have seen a proposal for remedying the difficulty we refer to, by placing a small spirit lamp under the rubber of the machine, and another under the conductor. This method may certainly, in some degree, prove beneficial; but it will be found to be in many respects inferior to the simple method here offered. In the first place, the radiation of heat will be neither so general nor so great; in the second place, the flame of a lamp or a candle absorbs the fluid; and in the third place, the *light*, which must necessarily be emitted from two spirit lamps, would prove highly detrimental to the effect of those experiments which require to be performed in darkness. To which may be added, the expense of the lamps, and the spirit to be consumed. Where a plate machine of large dimensions is used, this additional article will not be required; for the great thickness of the glass renders it capable of retaining the heat much longer than can be done by a thin cylinder; for which reason it must be obvious that if cylinders were made much stronger than they generally are, their action would be effectual for a greater length of time than it is. Opinion, however, runs in favour of thin cylinders, but the consistency of such opinion remains to be shewn. It is well known that the old globular machines, which were made of thick glass, when once put in a state of powerful excitation, retain that state much longer than the modern thin cylinder will do under the same circumstances.

The best *amalgam* for electrical machines is thus made. Melt in an iron ladle two ounces of zinc with one ounce of tin, and while this mixture is in a fluid state, pour into it six ounces of mercury; let the whole be then put into an iron or wooden box, and agitated until it be quite cold. In must then be reduced to fine powder in a mortar, and mixed with sweet hog's lard to the consistence of thick paste. This part of the process need not be performed till the amalgam is wanted for use.

OF ELECTRICAL APPARATUS.

The various articles of apparatus necessary for the exhibition of the most usual experiments in electricity, are insulating stands, or supports of various forms, wires, fine brass chains, a few spare brass balls of different sizes that may be screwed on wires when wanted; a few pith balls, two or three glass tubes of about three quarters of an inch in diameter, and from three to five feet in length; a large stick of sealing-wax; and four or five coated jars of different sizes. Electrical apparatus may be multiplied to a very great extent; but the electrician who understands the construction of his apparatus can readily combine even a small portion of it in so many different ways that he may save himself from an enormous expense by the exercise of his own ingenuity. No person, indeed, who is not competent to handle electrical apparatus with the skill of a workman, ought ever to venture beyond the most common-place experiments, at least where expense is any object.

The application of the apparatus to the purpose of experiment will best explain the nature of its different parts; and, in adopting this plan, we shall be enabled to give such an arranged view of the chief properties of the electrical fluid as may be of service in aiding the inexperienced electrician in making an orderly display, instead of a series of experiments which have no regular connection, and in which, sometimes one property, and sometimes another, is illustrated.

Attraction and Repulsion.

1. Excite a glass tube, by rubbing it for a few seconds with a silk handkerchief that has a little amalgam spread upon that part of it which touches the tube; hold the excited tube over some small bits of leaf gold, placed on a metallic plate, or on a smooth table, and they will be immediately attracted by the tube, between which and the table they may be made to pass up and down with great rapidity for a considerable time.

2. Bring an excited tube near a small downy feather; the feather will be attracted by the tube, and will cling to it till it be saturated with the fluid; it will then be repelled, and may be kept floating about in the room, by occasionally approaching it with the tube, from which it will recede, so long as it retains the electricity which it carried off from the tube.

3. By a fine flaxen thread attach a large downy feather to the prime conductor of the machine; turn the cylinder gently round, and the fibres of the feather will repel each other; approach it with a brass ball, or with the closed hand, and it will endeavour to turn itself towards the ball or hand, but present a pointed wire to it, and it will instantly shrink from it back on the conductor, as if animated, which arises from its being suddenly deprived of its electricity by the point.

4. This experiment may be varied by inserting the brass stem of Fig. 3. Plate XIV. into one of the holes in the prime conductor. The action of the machine will cause the hairs on the head to diverge from each other, and to stand on end.

5. By means of a pointed wire projecting a few inches from the prime conductor, electrify the inside of a large dry glass tumbler, then place it over about a dozen of small pith balls on a table, and the balls will be alternately attracted and repelled, at first with great rapidity, but the motion will become gradually more languid until it entirely cease. An instrument is constructed on purpose for this experiment, by which the dancing of the balls may be kept up for any length of time, as it may be connected with the conductor. See Fig. 4.

6. Suspend from the conductor, by a brass chain, a circular plate of copper, and reaching to within an inch and a half, or two inches of the table. Directly under this plate, place another of the same form and a little larger on

the table. Turn the machine, and the fluid will pass from the upper to the lower plate. If now small figures fancifully cut out of pasteboard, or pith of elder, be introduced between the plates, they will dance about with apparent vivacity, and sometimes appear to course round the edge of the lower plate. See Fig. 5.

7. *The electrical bells* furnish a pleasing illustration of the attraction and repulsion of the electric matter. They are variously constructed, but the form exhibited Fig. 6, is the simplest. The two outer bells are suspended by brass chains; the middle bell and the two clappers by fine silk threads. When the bells are attached to the conductor, and the machine is turned very slowly, the fluid will pass along the chains to the two outer bells, but will not pass along the silk to the clappers and middle bell. Thus the outer bells being charged with an extra quantity of electricity, will attract the clappers, but the moment they touch the bells, they become charged, and are repelled with such force as to cause them to strike against the middle bell, on which they deposit their electricity, and are again attracted. By this means a constant ringing is kept up while the machine is turned. From the inside of the middle bell a brass chain passes to the table for the purpose of conveying away the fluid deposited on it by the clappers.

Effect of Points on the Electric Fluid.

The effect of pointed conductors on the electric fluid may be illustrated by a great variety of pleasing experiments. The following are perhaps the most striking. 1. The *electrical fly.* Fig. 7. represents a light brass fly consisting of fine wires proceeding from a common centre, and having their pointed ends turned back at right angles, and all in the same direction. If this fly be poised on its centre on a pointed wire inserted in the prime conductor, and the machine be put in action, a stream of fluid will issue from each point, and produce a loco-motion in the fly, propelling it in a direction contrary to that of the points: the points will of course appear luminous, and if the room be darkened, a beautiful circle of fire will be distinctly seen, formed by the revolution of the fly. On the same principle motion is communicated to, 2. *The Electrical Orrery.* This instrument is represented by Fig. 8. The ball S represents the sun, L the earth, and M the moon, connected by the wires *a c* and *b d*: *b* is the centre of gravity between the earth and moon.

These three balls and their connecting wires are supported on the sharp point of a wire A, which is inserted in a hole in the prime conductor, and must stand perfectly upright and steady; the earth and moon hanging on the sharp point of the wire *c a e*. From the side of each ball a short pointed wire projects horizontally, from which the fluid passes off in a stream when the machine is worked, and thus motion is given to the whole; the sun and earth moving round their common centre of gravity *a*; and the earth and moon round theirs at *b*. The weights of the balls may be so nicely adjusted that E and M will make *twelve* revolutions round *b*, in the time that S and E make *one* round *a*.

8. *The Electrical Inclined Plane.* This is a highly beautiful experiment, and satisfactorily shews that the electrical matter issuing from a number of points, possesses force sufficient to counteract the power of gravity in light bodies. Fig. 9 represents the inclined plane, where A is a board of mahogany 14 inches long, and 4 inches broad; B B B B are four glass pillars, three tenths of an inch in thickness, the length of the two longer is seven inches, and that of the two shorter is five inches.

From the longer to the shorter pillars, are stretched two fine brass wires, parallel to each other, and tightened by screws which pass through the brass balls which surmount the pillars. On these wires the axis of the fly C rests, the ends of which are formed like a small pulley, having a groove in them to prevent their slipping off the wires, and to guide the fly when in action. It is obvious that if the fly be placed on the upper part of the wires, it will roll down them by its own gravity; but when it has reached the bottom of the plane, if the upper end of the wires be connected with the machine while in action, the escape of the fluid from the points will cause it to roll very rapidly up the plane till it reach the top of it.

These experiments may be varied to a great extent, and models of corn-mills, water-pumps, astronomical clocks, &c., constructed of cork and paste-board, are readily put in action, by directing against their main wheels, a stream of electricity from a strong pointed wire inserted into the prime conductor.

Of the Leyden Jar.

The Leyden jar, or phial, is so called from the circumstance of its properties having been first observed at Leyden by M. Van Kleist, dean of the cathedral in Camin. It consists of a glass jar of any convenient size, having the outside and inside coated with tin foil, to within 2 or 3 inches of the top, and a brass wire, the upper part of which must terminate in a ball of the same metal, and the lower part in a fine chain, or a piece of fine wire, that it may touch the inside of the jar, passing through a lid of baked wood which fits into the mouth of the jar. This jar, as commonly used, is represented by Fig. 10. If a jar thus constructed be held by the lower part with the hand, and the knob be brought in contact with the prime conductor while the machine is in action it will become charged; and if a communication be then formed between its outside and inside coatings, by the other hand being brought to the knob, that sensation called the electrical shock will be felt, and the jar will thus be discharged. But when it is required to pass the charge of the jar through any particular substance, the jointed discharging rod must be used, Fig. 11, which is mounted on a glass handle to prevent the dispersion of the fluid. Any number of these jars combined together, and having a communication formed between their exterior and interior coatings, is called an electrical battery. Fig. 1. Plate XV. For experiments that do not require great power, two or three jars are sometimes connected together by wires; and this is often more convenient than charging the battery; but where great power is required, the battery is indispensable to success. In using a single jar it is often desirable, and sometimes even necessary to measure accurately the strength of the charge. This is effected by means of an instrument called the electrometer, the simplest form of which is represented by Fig. 2. and consists of an upright stem of box, furnished at the lower end with a brass ferule

and pin, by which it may be inserted in the conductor. To the upper part of the stem is affixed a graduated semicircle of ivory, about the middle of which is a brass arm, to support the axis of the index. The index is a very slender stick, which reaches from the centre of the plate to the ferule at the lower end of the stem; and to its extremity is fixed a delicate pith ball. This index rises as the charge proceeds, and when it is completed will stand at ninety, or at right angles with the stem.

The *universal discharger* is another instrument that will be found necessary in a great variety of experiments in which the battery is to be used.

Fig. 3. is a representation of Henley's universal discharger. A is a flat board, about fifteen inches long, four broad, and one thick. B B are two glass pillars, cemented in two holes upon the board A, and furnished at top with brass caps, each of which has a turning joint, and supports a spring tube, through which the wires D D slide. Each of the caps is composed of three pieces of brass, connected so that the wires D D, besides their sliding through the sockets, have a horizontal and vertical motion. Each of the wires D D is furnished with an open ring at one end, and at the other it has a brass ball, which, by a short spring socket, is slipped upon the pointed extremity, and may be removed. E is a circular piece of wood, having on its surface a slip of ivory inlaid, and furnished with a foot, which is fastened in the middle of the bottom A.

To this discharger belongs the small press, Fig. 4. the stem of which fits into the socket, instead of the circular table E. On the top of the stem are two oblong boards, which are pressed together by means of two screws. Between these boards may be placed any substance which requires to be pressed while the electric fluid is sent through it.

The construction of this instrument is such as to enable the operator to use it with advantage in numerous experiments, such as the oxidation of metallic leaves between slips of card or of glass; splitting small pieces of oak; firing gunpowder, &c.

By far the most interesting and brilliant application of the powers of the Leyden jar, is the melting of metallic wires. When a strong charge is passed through a slender iron wire, the wire is ignited or dispersed in red-hot globules. The power of large batteries was formerly considered essential to the production of this effect; but if the wire be sufficiently fine, a single jar, exposing a coated surface of about 190 square inches, will be found sufficient to exemplify the experiment. The finest flatted steel wire, sold at the watch-makers' tool shops, by the name of watch-pendulum wire, answers exceedingly well.

Cuthbertson's Balance Electrometer is an excellent and elegant regulator of the strength of the charge requisite for fusing different lengths of wire; and in public lectures is an indispensable article of apparatus. Fig. 5. represents this instrument, with the common quadrant electrometer inserted in the centre of the upper arm, which, it may be sufficient to mention, is accurately poised on a knife-edged centre. In using this electrometer, the arm A must be connected with the inside of the jar, and the insulated ball B with the outside. The wire to be fused must form part of the circuit. When the jar or battery is charged, C will be repelled by A, and D will thus descend to B, and discharge the jar or battery through the wire, which will be fused and run into balls. From numerous experiments it appears that the action of electricity on wires increases in the ratio of the square of the increased power; since *two* jars, charged to any degree, will melt four times the length of wire that is melted by *one jar*; and this will again be *quadrupled*, by *doubling* the height of the charge.

This law, Mr. Singer says he has found to obtain in all accurate experiments, with moderate lengths of wire: with a battery exposing forty feet of coated surface, he has frequently melted eighteen feet of iron wire, ($\frac{1}{250}$th of an inch diameter) by a single explosion, and the phenomena were remarkably brilliant, a shower of intensely ignited globules being dispersed in all directions.

Inflammable substances kindled by the electric fluid.

If a small quantity of spirit of wine be poured into a silver table spoon, and rendered a little warm by being held over a clear fire, it may be inflamed, by drawing from it a single spark, when the spoon is held by a person standing on the insulating stool, and holding in his other hand a chain, connected with the prime conductor. This experiment is sometimes varied, and rendered more striking in the following manner. Near the prime conductor of the machine, place on the table three wine glasses; connect the first glass with the conductor, by a brass chain, which will reach to the bottom of it, and with it, let the second and third be connected by a piece of fine brass wire, bent in the form of the letter A. Fill the first and second glasses with water, and into the third pour a little ether; turn the machine, and with a wire and ball, draw a spark from the ether and it will be immediately inflamed.

Gun-powder may be fired by the charge of a jar sent through it, if it be ground fine, and slightly rammed into a quill: there must be a brass wire inserted in each end of the quill; the wires should be thrust so far in, that their extremities may be within the fifth of an inch of each other. If the powder be mixed with clean steel filings, it will be the more readily fired.

If a small quantity of flax, or of cotton wool be *loosely* tied on one of the knobs of the discharging rod, and a little finely powdered resin dusted on it, and a jar be discharged by bringing the end of the rod thus prepared in contact with the knob of the jar, the charge will pass through the flax, or wool, and in so doing will melt and ignite the resin, and set the whole on fire. A very neat contrivance for giving this experiment a better effect is represented by Fig. 6. A is a mahogany board six inches in length, three in breadth, and half an inch in thickness. B is a glass pillar fixed in the middle of A, and supporting a piece of wood C, which is three inches long, an inch and a half broad, and about three quarters of an inch thick. In each end of this piece there is a small screw-ring: the extremities of these screws just touch a wire proceeding to each of them from two small brass knobs inserted at the ends of a shallow groove on the upper side of C; these rings serve to hook the chains or

when the instrument is used. On the back part of C stands the perpendicular piece D, in the top of which is fixed the brass pin E. To use this for the purpose of firing cotton wool it is only necessary to dust the cotton with powdered rosin, and hang it on the pin E, letting the lower part of it reach down to the piece C Connect one end of C with the inside of a jar and the other end with the outside; discharge the jar and the fluid in passing between the two small brass knobs will kindle the cotton. This neat little instrument is the invention of Dr. Roberts of Bridport.

Hydrogen gas may be readily inflamed by the electric spark. Fig. 7. is a representation of the electrical cannon chiefly used for this purpose. It is charged with the gas by holding the mouth of it closely over that of a stone or glass bottle in which the gas is generated; a few seconds will be sufficient; it must then be corked up, and the person who is to discharge it, standing on the insulating stool, must touch with his finger, or with a wire and ball, the knob A, and the spark will pass into the interior of the cannon through the glass tube B, and the gas will explode with a loud report, driving out the cork from the mouth of the cannon to a considerable distance.

Luminous exhibition of the electric fluid.

This effect is produced to the greatest advantage by forming different devices with spangles of tin foil on the surfaces of tubes, or plates of glass, and sending a succession of strong sparks along such devices; the spangles should be placed at a short distance from each other, and fixed on with strong gum water.

A mere inspection of the figures will convey an accurate idea of the nature of this kind of electrical apparatus: and it is only necessary to observe that the brilliancy of these exhibitions will depend on the darkness of the room in which they are made, the dryness of the apparatus, and the strength of the sparks. Fig. 8. is a representation of the simplest instrument used for this purpose; from the form of the direction in which the spangles are stuck on the glass, it is called the spiral tube. When used it is held in the hand by one end, while the other is brought sufficiently near the prime conductor to receive the spark.

Fig. 9. shews a combination of such tubes called the *illuminated dome*, the effect of which is extremely vivid when the experiment is well managed: Fig. 10. is a device for exhibiting the luminous appearance of the fluid through different colours painted on glass, the effect of this is also remarkably fine.

It is not necessary here to occupy the time of the reader with directions how to perform experiments of this description, since all that is required is to employ a machine of self-sufficient power to keep up a constant and vivid stream of the electrical matter, and to take care that there be a good conducting substance connected with the termination of the device to carry off the fluid to the earth.

The identity of lightning and the electric fluid.

Various proofs of this have been adduced by the best writers on electricity; but instead of enumerating them here it may be sufficient to observe that in as far as the limited powers of man have been able to carry experiment on the subject, nothing has yet occurred that can be mentioned as indicating the least difference, except in quantity, between the substance that flows so copiously from a good electrical machine, and that which flashes in the heavens producing some of the most awfully sublime phenomena in nature. But it is in the power of any person capable of using the common electrical apparatus to satisfy himself on this head by raising in the air a common paper kite having a pointed wire projecting a few inches from its highest part, and communicating with the string by which the kite is raised. In this string there should be a very fine thread of wire intertwined, such as is used by the manufacturers of metallic lace; or if this cannot be obtained the string may be simply wetted with water. If a kite thus prepared be raised in the air during a thunder storm, or at any other time when there is much electricity present, the fluid will descend copiously along the string, and may be collected in jars, and every kind of experiment performed with it as if it had been collected from a machine.

In making this experiment the string of the kite should be coiled round a rod of glass; and a chain should be suspended from it so as to touch the ground, as the electric matter sometimes flows down in such quantities as might prove dangerous to the operator were it not immediately conveyed to the earth.

The knowledge of the identity of lightning and the electric matter produced by the machine has been turned to great advantage in the production of those inventions by which not only valuable property, but, in many instances, human life also may be protected from the destructive effects of this powerful agent of nature. Valuable, however, as these inventions are, they are comparatively little attended to. Every building that stands in an exposed situation ought to be furnished with a conducting rod to save it from the effects of lightning; yet conductors on buildings are more curious than common in England; nay, what is still worse, church spires are but seldom provided with them, although they are generally surmounted by gilt ornaments peculiarly adapted to draw the lightning from the clouds. Ships that go within the tropical climates ought to be provided with the flexible conductors which are so easily adapted to the masts, and which prove a source of safety in the most violent thunder-storms, and yet it is said that masters of vessels sometimes carry these rods out with them, without being at the trouble of having them erected.

The utility of conductors is demonstrated by the common experiment called the thunder-house. This little article is variously constructed, but the most elegant form given to it, and that which shews the effect most strikingly is that represented by Fig. 11. The upper part of the pyramid consists of three distinct pieces, which are all thrown asunder by falling down when the moveable piece *a* is expelled by the charge passing along the conducting rod.

In treating of the luminous appearance of the electric fluid we should have noticed the singularly beautiful effect produced by passing it through a highly rarified medium.

The appearance of the fluid in this case strikingly resembles the *Aurora Borealis*; from which it has been thought that that phenomenon

is caused by the electricity of the atmosphere playing in the higher regions. This theory, however, is not well supported, and some recent facts seem to militate against it. To produce this exhibition a long glass tube, so mounted that it may be readily exhausted of the internal air, is essentially necessary. For this experiment and numerous others which we have not room to describe, we would warmly recommend the compound apparatus which is represented at Fig. 12. A is an insulating pillar of glass, which is screwed to the wooden foot B; and on this pillar all the apparatus may be screwed alternately. C D is an exhausted tube of glass, furnished at each end with brass caps; at the end D is a valve properly secured under the brass plate; a brass wire, with a ball, projects from the upper cap; a pointed wire proceeds from the bottom plate; and this tube is called the LUMINOUS CONDUCTOR. The flask represented at E is called the LEYDEN VACUUM. It is furnished with a valve under the ball E; to come at which the more readily, the ball may be unscrewed: a wire, with a blunt end, projects to within a little of the bottom of the flask, the latter being coated with tin foil: and a female screw is cemented to the bottom, to screw it on the pillar A.—F is a syringe to exhaust the air occasionally, either from the luminous conductor or the Leyden vacuum. To do this, unscrew the ball of the Leyden vacuum, or the plate of the luminous conductor, and then screw the syringe in the place of either of these pieces, being careful that the bottom of the female screw G bears close against the leather which covers the shoulders *a b* or *c d;* then work the syringe, and in a few minutes the glasses will be sufficiently exhausted. H and I are two Leyden bottles; each of which has a female screw fitted to the bottom, that they may be conveniently screwed on the pillar A; and the bottle H is furnished with a belt by which it may be screwed sidewise to the same. K and L are two small wires, to be screwed occasionally either into the ball E, the knobs *e* or *f*, the cap *c*, or the socket *g* on the top of the pillar; the balls may be unscrewed from these wires, which will then exhibit a blunt point. M is a wooden table to be screwed occasionally on the glass pillar.

Of the two Electricities.

There are two distinct kinds of electricity which were originally named by Du Fay, who made the discovery, the *vitreous* and the *resinous,* but are now denominated *positive* and *negative* electricity.

In whatever way electricity is produced, whether by friction, evaporation, heating or cooling, there is always the presence of the two distinct electricities. And it is now well known that *every* substance is an electric, or capable by friction of producing electrical phenomena. Thus for, instance, if we take any of those bodies formerly called non-electrics, and insulating it by a rod of glass or of any other convenient substance commonly termed an electric, and rub it with a piece of silk, or worsted, we shall find it become electrical. It will attract and repel light bodies, and yield sparks to the finger that approaches it: the distinction, therefore, formerly made between electrics, and non-electrics is groundless, and calculated to mislead.

On this principle we readily perceive how any body by friction may be made to exhibit either of the two electricities, according to the nature of the rubber. The only exception is the back of a cat, which gives the vitreous or positive electricity with every rubber hitherto tried.

The following is a table of several substances which acquire the vitreous electricity, when we rub them with those which follow them in the list; and the resinous electricity, when rubbed with those that precede them.

The skin of a cat.
Polished or smooth glass.
Woollen stuff or worsted.
Feathers.
Dry wood.
Paper.
Silk.
Lac.
Roughened glass.

The resulting fluids are necessarily co-existent, the one appearing on the body rubbed, and the other on the rubber; but since the one is most usually evolved on the surface-glass, and the other on that of resins, the first has been called the vitreous, and the second the resinous electricity. These two fluids, corresponding to the positive and negative of Franklin, by their reunion produce a species of reciprocal neutralization, and electrical repose.

This may be most satisfactorily shewn by the following simple experiment. Excite a glass tube by friction, and bring it gradually towards the gold-leaf electrometer Fig. 13. and the leaves will diverge with positive electricity. The same effect will be produced, but by negative electricity, by exciting a large stick of sealing wax. But let both the glass and the wax be excited at the same time, then, holding them in a perpendicular direction, parallel to, and at a little distance from each other, bring them near the electrometer, and not the slightest sign of electricity will be evinced by it.

To the scientific mind the exhibition of the two electricities must ever form a source of superior gratification in consequence of the indefinite variety of which the illustrative experiments admit; the ease with which most of them may be performed; and the extreme beauty and delicacy of many of them. But on this part of the subject we cannot enlarge; nor have we room to enter on the connexion of electricity with the medical science. Yet we must take this opportunity of stating, that, although there are many foolish, and even incredible things on record, as to the medical virtues of electricity, we have also sufficient proof that in the hands of a skilful operator, it may, in numerous cases, be applied with certainty of success.

Let no one however attempt to apply this agent in the healing art who is not thoroughly competent to judge of the real nature of the case, and to manage the application with prudence and skill.

The Electrophorus.

The electrophorus is certainly a very remarkable source of electrical accumulation, and is an instrument which, for many light experiments, forms a good substitute for the electrical machine. It is one of the ingenious contrivances of professor Volta, and is constructed

in the following manner. Procure two circular plates of metal, or of wood covered with tin foil, and well rounded at the edges; these are the conductors: between them is placed a resinous plate, formed by melting together equal parts of shell-lac, resin, and Venice turpentine, and pouring this mixture, whilst fluid, within a tin hoop of the required size, placed on a marble table, from which the plate may be readily separated when cold. This plate should be half an inch in thickness; it is sometimes made by pouring the mixture on one of the conductors, which is then formed with a rim for that purpose. In the centre of the upper conductor is fixed a glass handle of about ten inches long, for the purpose of lifting it without drawing off its electricity; and when the electric state of the lower conductor is to be examined, the whole apparatus must be placed on an insulating stand. To use the electrophorus, rub the upper surface of the resinous plate with a piece of dry fur, cat's skin is reckoned the best, and it will be excited negatively. Place the upper conductor upon it, and then raise the same by its insulating handle; it will be found to exhibit very faint, if any, electrical signs. Replace the conductor, and whilst it lies on the surface of the excited plate, touch it with a finger or any other uninsulated conductor, and then raise it again by its handle. It will now be positively electrified, and afford a spark: if it be then replaced on the resinous plate, touched, and again raised, another spark will be procured, and this process may be repeated for a considerable time without any perceptible diminution of effect. Jars may be charged by bringing them in contact with the conductor each time it is lifted, with an instrument of this kind only six inches in diameter. Cavallo charged a jar several times successively, and such was the strength of the charge that it was capable of piercing a card.

This instrument, properly constructed, has been known to retain its electricity so long as three weeks, without requiring fresh excitation.

Fig. 12. Plate XIII, represents the most common form of the electrophorus; it is sometimes fitted up with a contrivance for producing an instantaneous light by causing the spark to inflame hydrogen gas.

ELECTRO CHEMISTRY. See GALVANISM.

ELECTUARY, in pharmacy, a term in which both official and extemporaneous medicines are frequently made.

ELEGIA, a genus of the dioecia triandria class and order. There is one species, a native of the Cape, which has the habit of the rush.

ELEGIT, in law, is a writ of execution, either upon a judgment for debt or damages, or upon a forfeiture of the recognizance, taken in the King's court, by which the plaintiff is put in possession of one half the debtor's lands, which he is possessed of at the time to hold them till his debt is paid out of the profits.

ELEGY, a mournful and plaintive kind of poem. See POETRY.

ELEMENT, in physiology, a term used by philosophers to denote the original component parts of bodies, or those into which they are ultimately resolvable.

It seems to have been an opinion established among philosophers in the remotest ages, that there ar[illegible]ly four simple bodies, namely, fire, air, water, and earth. To these they gave the name of elements, because they believed that all substances are composed of these four. This opinion, variously modified indeed, was maintained by all the antient philosophers. We now know that all these supposed elements are compounds: fire is composed of caloric and light; air of caloric, oxygen and azotic gases; water of oxygen and hydrogen and the earth includes nine different substances.

ELENCHUS, in logic, a sophism, or fallacious argument, which deceives the hearer under the appearance of truth.

ELEPHAS, the ELEPHANT, a genus of the mammalia class, of the order bruta. The generic character is, cutting teeth none in either jaw; tusks in the upper jaw; proboscis very long, prehensile; body nearly naked.

The above is according to the classification of Linnæus, but by Cuvier the elephant placed among the pachydermera, or thick-skinned quadrupeds, in company with the sow, the river horse, and the rhinoceros; and under this genus are now ranked the following species.

1. *Elephas Africanus*, the African elephant. In this species the skull is rounded, processes of the enamel of the grinders forming a series of lozenges, touching each other in the middle; ears large; toes four before and three behind. The tusks of this species yield the best ivory, and are the largest in point of size. The hide is of a deep brown colour; and the ordinary height is from eight to upwards of ten feet. This animal inhabits the immense forests and the dreary wastes of Africa.

2. *Elephas Indicus*, Asiatic Elephant. The skull of this species is lengthened, the forehead concave, the enamel of the grinders disposed in the form of flattened ovals placed across the tooth; ears large, horny nails, five before and four behind. The general colour of this species is grey, speckled with brown, and sometimes white. The height is from eight to twelve feet.

This species inhabits the continent of Asia, and is found on both sides of the Ganges, in China, and in the larger islands of the Indian Ocean.

3. *Elephas Primigenius*. Fossil elephant, or mammoth. The skull is lengthened, forehead concave, under jaw, obtuse, grinders large, parallel processes of the enamel disposed in closely set ribbands, sockets of the tusks very long.

This species in all probability is now extinct, and it is only known from the numerous specimens of its bones which have been dug out of the earth: these are of immense size, and have been found in all the countries of Europe, from the Mediterranean sea to the arctic circle. In Asiatic Russia they occur in the greatest abundance.

They have also been found in the European isles, as Iceland, and various parts of Great Britain and Ireland; they have been dug up also in North and South America, and in Hudson's Bay.

The contrivances for taking elephants are various. The Ceylonese sometimes surround

the woods in bands, and drive, with lighted torches and all manner of noises, the elephants which inhabit them, till they are entrapped into a particular spot surrounded with pallisades. At other times a kind of decoy, or female elephant, is sent out in order to induce some of the males to pursue her, who are by this means secured. When a wild elephant is taken, it still remains to reduce it to a quiet state: and to tame it, in order to be made useful: this is effected by throwing ropes round the legs and body, which are well secured; and two tame elephants, properly instructed, are placed on each side. The captive animal finds himself gradually so fatigued by his ineffectual struggles, and so much soothed by the caresses occasionally given by the trunks of the tame elephants, by the food from time to time presented to him, and the water with which he is refreshed by pouring it over him, that in the space of some days he becomes completely tame, and is placed with the rest of the domesticated troop. Sometimes, in order to subdue them the more effectually, they are deprived of sleep for a considerable time.

The elephant brings only one young at a time; very rarely two: the young are about three feet high when they are first born, and continue growing till they are sixteen or twenty years old; they are said to live a hundred, or a hundred and twenty years.

In the Philosophical Transactions for the year 1799, we find some curious particulars relative to the natural history of the elephant, by Mr. Corse, whose residence in India afforded him opportunities of investigating the subject with exactness.

From these observations it appears that something must be subtracted from that elevated character with which this animal has been so frequently honoured; and that neither its docility nor its memory can be allowed a very high rank, when compared with those of some other animals; and that the scrupulous delicacy, which, as it was pretended, forbade all public demonstrations of its passions, is a mere fable. A female elephant has also been known to forget her young one, after having been separated from it for the short space of only two days, and to repel its advances. An elephant, also, which had escaped from its confinement, has again suffered itself to be trepanned, and reconducted to its state of captivity.

ELEPHANTIASIS, called also the lepra of the Arabians, in medicine, a chronical disease, one of the two species of leprosy, which affects the whole body, where even the bones as well as the skin are covered with spots and tumours, which being red, at last turn black.

ELEPHANTOPUS, *bastard-scabius*, in botany, a genus of the syngenesia polygamia segregata class of plants. There are four species, herbaceous plants of the East and West Indies.

ELEVATION, *angle of*, in gunnery, that comprehended between the horizon and the line of direction of a cannon or mortar; or it is that which the chase of a piece, or the axis of its hollow cylinder, makes with the plane of the horizon.

ELEVATION, in architecture, the same with an orthographic or upright draught of a building.

ELEVATION *of the host*, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to adore.

ELEVATOR, the name of several muscles. See ANATOMY.

ELEVATORY, *elevatorium*, in surgery, an instrument for raising depressed or fractured parts of the scull, to be applied after the teguments and periosteum are removed.

ELISION, in grammar, the cutting off or suppressing a vowel at the end of a word, for the sake of sound or measure, the next word beginning with a vowel.

ELK. See CERVUS.

ELL, a measure of length, different in different countries; but those mostly used in England, are the English and Flemish ells, whereof the former is three feet nine inches, or one yard and a quarter, and the latter only twenty-seven inches, or three quarters of a yard. In Scotland, the ell contains $37\frac{2}{10}$ English inches.

ELLIPSIS, in geometry, a curve line returning into itself, and produced from the section of a cone by a plane cutting both its sides, but not parallel to the base. See CONIC SECTIONS, and MENSURATION.

ELLIPSIS, in grammar, a figure of syntax, wherein one or more words are not expressed; and from this deficiency it has got the name ellipsis.

ELLIPSIS, in rhetoric, a figure nearly allied to preterition, when the orator, through transport of passion, passes over many things: which, had he been cool, ought to have been mentioned.

ELLIPTOIDES, in geometry, a name used by some to denote infinite ellipses, defined by the equation $ay^{m+n} = bx^m (a-x)^n$.

Of these there are several sorts: thus, if $ay^3 = bx^2 (a-x)$ it is a cubical elliptoid; and if $ay^4 = bx^2 (a-x)^2$, it denotes a biquadratic elliptoid, which is an ellipsis of the third order in respect of the appollonian ellipsis.

ELLISIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 23d order, luridæ. There is one species, an annual plant of Virginia.

ELOCUTION, in rhetoric, the adapting words and sentences to the things or sentiments to be expressed. It consists of elegance, composition, and dignity. The first, comprehending the purity and perspicuity of a language, is the foundation of elocution. The second ranges the words in proper order; and the last adds the ornaments of tropes and figures to give strength and dignity to the whole.

ELONGATION, in astronomy, the digression or recess of a planet from the sun, with respect to an eye placed on our earth. The term is chiefly used in speaking of Venus and Mercury, the arch of a great circle intercepted between either of these planets and the sun, being called the elongation of that planet from the sun.

ELONGATION is also used for the difference in motion between the swiftest and the slowest of two planets, or the quantity of space the one has passed beyond the other

ELOPS, a genus of fishes of the order of abdominales, of which there is but a single species, viz. the saurus, or scar-fish, which inhabits the coast of Carolina.

ELYMUS, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the fourth order, *gramina*. There are 11 species, known in general by the name of lyme grass; they may be found in most parts of the world.

EMBALMING, is the opening of a dead body, taking out the intestines, and filling the place with odoriferous and desiccative drugs and spices, to prevent its putrifying. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some that they have embalmed upwards of 2000 years ago, remain whole to this day, and are often brought into other countries as great curiosities.

EMBARGO, in commerce, an arrest on ships, or merchandize, by public authority; or a prohibition of the state, commonly on foreign ships, in time of war, to prevent their going out of port, sometimes to prevent their coming in, and sometimes both, for a limited time.

EMBERIZA, in ornithology, a genus of birds belonging to the order of passeres. There are 24 species, of which the most remarkable are,

1. The nivalis, or great pyed mountain finch of Ray, and the snow-bird of Edwards; it has white wings, but the outer edges of the primo feathers are black; the tail is black, with three white feathers on each side. These birds are called in Scotland snow flakes, from their appearance in hard weather and deep snows. They arrive in that season among the Cheviot-hills and in the Highlands in amazing flocks.

2. The miliaris, or grey emberiza, is of a greyish colour, spotted with black in the belly, and the orbits are reddish. It is the bunting of English authors, and a bird of Europe.

3. The hortulana, or ortolan, has black wings; the first three feathers on the tail are white on the edges, only the two lateral are black outwardly. The orbits of the eyes are naked and yellow; the head is greenish, and yellow towards the inferior mandible. It feeds principally upon the millet, grows very fat, and is reckoned a delicate morsel by certain epicures, especially when fattened artificially. These birds are found in several parts of Europe, but are not met with in Britain.

4. The citrinella, or yellow-hammer, has a blackish tail, only the two outward side-feathers are marked on the inner edge with sharp white spots. It is a bird of Europe, and comes about houses in winter.

5 The schœniclus, or reed-sparrow, has a black head, a blackish-grey body, and a white spot on the quill-feathers. It inhabits marshy places, most commonly among reeds, from which it takes its name. Its nest is worthy of notice for the artful contrivance of it, being fastened to four reeds, and suspended by them like a hammock, about three feet above the water.

6. The oryzivora, or rice-bunting, with the head and whole under-side of the body black; hind part of the neck in some pale yellow, and in others white; coverts of the wings and primaries, black, the last edged with white; part of the scapulars, lesser coverts of the wings, and rump, white; back black, edged with dull yellow; tail of the same colours, and each feather sharply pointed; the legs are red.

7. The cirlus is brown; breast spotted; eyebrows pale yellow; the two outmost tail-feathers with a white wedged spot. It inhabits France and Italy, and feeds on seeds, worms, and insects.

8. The ciris; the head blue; belly orange; back green; the feathers green brown. Inhabits South America.

EMBLEM, a kind of painted enigma, or certain figures painted or cut metaphorically, expressing some action, with reflections underneath, which, in some measure, explain the sense of the device, and at the same time instruct us in some moral truth, or other matter of knowledge. The emblem is somewhat plainer than the enigma, and the invention is more modern, it being entirely unknown to the ancients.

EMBOSSING, or *imbossing*, in architecture and sculpture, the forming or fashioning works in relievo, whether cut with a chissel or otherwise.

EMBOTHRUN, a genus of the class and order tetrandria monogynia. There are four species, handsome shrubs of New Holland and South America.

EMBRASURE. See ARCHITECTURE.

EMBRASURE, in fortification, a hole or aperture in a parapet through which the cannon are pointed to fire into the moat or field.

EMBROCATION, in surgery and pharmacy, an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c.

EMBROIDERY, a work in gold or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked. As to muslin, they spread it upon a pattern ready designed; and sometimes, before it is stretched upon the pattern, it is starched, to make it more easy to handle.

EMERALD, in natural history, a precious stone, of a green colour, and next in hardness to the ruby.

Its texture is foliated. Its fracture conchoidal. Causes a double refraction. Hardness 12. Specific gravity 2.9. to 3.3. Colour green. Becomes electric by friction, but not by heat. Its power does not phosphoresce when thrown on a hot iron. At 150° Wedgewood it melts into an opaque coloured mass. According to Dolomieu, it is fusible per se by the blowpipe.

This mineral was formerly subdivided into two species; the emerald, and beryl or aqua marina. Hauy demonstrated, that the emerald and beryl correspond exactly in their structure and properties; and Vauquelin found that they were composed of the same ingredients; henceforth, therefore, they must be considered as varieties of the same species.

EMERSION, in astronomy, is when any planet that is eclipsed begins to emerge or get out of the shadow of the eclipsing body. It is also used when a star, before hidden by the sun as being too near him, begins to re-appear or emerge out of his rays.

EMERY. A sub-species of rhomboidal

corundum. Its colour is intermediate between greyish-black and bluish-grey. It occurs massive and disseminated, and also in granular concretions. Lustre, glistening and adamantine. Fracture, fine grained uneven. Translucent on the edges. So very hard as to scratch topaz. Difficultly frangible. Sp. gr. 4.0. Its constituents are 86 alumina, 3 silica, 4 iron, and 7 loss. In Saxony, it occurs in beds of talc and steatite. It occurs abundantly in the Isle of Naxos, and also at Smyrna. It is used for polishing hard minerals and metals. Its fine powder is obtained by trituration and elutriation.

EMOLLIENTS, in medicine and pharmacy, are such remedies as sheath and soften the asperity of the humours, and relax and supple the solids at the same time.

EMPETRUM, *berry-bearing heath*, a genus of the triandria order, in the monœcia class of plants. In the natural method this genus is ranked by Linnæus under the 54th order miscellaneæ; and likewise among those of which the order is doubtful. There are two species; one of which, viz. the nigrum, bears the crow-cake berries, and is a native of Britain. It grows wild on boggy heaths and mountains. Children sometimes eat the berries.

EMPIS, in zoology, a genus of insects belonging to the order diptera, of which the characters are these: the proboscis is of a horny substance, bivalve, reflected under the head and breast, and longer than the thorax. There are five species.

EMPLEURUM, a genus of the monœcia tetrandria class and order. The male calyx is four-cleft; corolla none; fem. calyx, four-cleft inferior; corolla none; stigma cylindric; caps. opening at the side; seed one, arilled. There is one species, a shrub of the Cape.

EMPYREUMA. This term is applied to denote the peculiar smell produced by a considerable heat upon vegetable or animal substances in closed vessels, or when burned under circumstances which prevent the access of air to a considerable part of the mass, and consequently occasion an imperfect combustion, or destructive distillation of the parts so covered up by the rest of the mass.

EMULSION. An imperfect combination of oil and water, by the intervention of some other substance capable of combining with both these substances. The substances are either saccharine or mucilaginous.

ENAMEL. There are two kinds of enamel, the opaque and the transparent. Transparent enamels are usually rendered opaque by adding putty, or the white oxide of tin, to them. The basis of all enamels is therefore a perfectly transparent and fusible glass. The oxide of tin renders this of a beautiful white, the perfection of which is greater when a small quantity of manganese is likewise added. If the oxide of tin be not sufficient to destroy the transparency of the mixture, it produces a semi-opaque glass, resembling the opal.

Yellow enamel is formed by the addition of oxide of lead or antimony. Kunckel likewise affirms, that a beautiful yellow may be obtained from silver.

Red enamel is afforded by the oxide of gold, and also by that of iron. The former is the most beautiful, and stands the fire very well, which the latter does not.

Oxide of copper affords a green; manganese, a violet; cobalt, a blue; and iron, a very fine black. A mixture of these different enamels produces a great variety of intermediate colours, according to their nature and proportion. In this branch of the art, the coloured enamels are sometimes mixed with each other, and sometimes the oxides are mixed before they are added to the vitreous bases.

In the Transactions of the Society of Arts for 1817, a valuable list of receipts for enamel colours is given by Mr. R. Wynn, for the communication of which a premium was awarded. The following are Mr. Wynn's fluxes:—

No. 1.	Red lead,	8 parts.
	Calcined borax,	1½
	Flint powder,	2
	Flint glass,	6
No. 2.	Flint glass,	10
	White arsenic,	1
	Nitre,	1
No. 3.	Red lead,	1
	Flint glass,	3
No. 4.	Red lead,	9½
	Borax not calcined,	5½
	Flint glass	8
No. 5.	Flint glass,	6
	Flux, No. 2.	4
	Red lead,	8

After the fluxes have been melted, they should be poured on a flag stone, wet with a sponge; or into a large pan of clean water, then dried, and finely pounded in a biscuit-ware mortar for use.

Yellow enamel.

Red led,	8
Oxide of antimony,	1
White oxide of tin.	1

Mix the ingredients well in a biscuit-ware mortar, and having put them on a piece of Dutch tile in the muffle, make it gradually red-hot, and suffer it to cool. Take of this mixture 1, of flux No. 4. 1½; grind them in water for use. By varying the proportions of red lead and antimony, different shades of colour may be obtained.

Orange.

Red lead,	12
Red sulphate of iron,	1
Oxide of antimony,	4
Flint powder,	3

After calcining these without melting, fuse 1 part of the compound with 2½ of flux.

Dark red.

Sulphate of iron calcined dark,	1	
Flux, No. 4.	6 parts	of this 3
Colcothar,	1	

Light Red.

Red sulphate of iron,	1
Flux, No. 1.	3
White lead,	1½

Brown.

Manganese,	2
Red lead,	8
Flint powder,	4

ENARGEA, a genus of the hexandria monogynia class and order. There is no calyx: the petals are six; berry three-celled; four or

five globular seeds. There is one species, a native of Terra del Fuego.

ENCAUSTIC, and **ENCAUSTUM**, the same with enamelling and enamel. See ENAMELLING, and ENAMEL.

ENCAUSTIC *painting*, a method of painting made use of by the ancients, in which wax was employed to give a gloss to their colours, and to preserve them from the injuries of the air See PAINTING.

ENCHASING, or *chasing*, the art of enriching and beautifying gold, silver, and other metal work, by some design, or figures represented thereon, in low relievo. See RELIEVO and SCULPTURE.

ENCHASING is practised only on hollow thin works, as watch-cases, cane-heads, or the like. It is performed by punching or driving out the metal, to form the figure, from withinside, so as to stand out prominent from the plane or surface of the metal. In order to this they provide a number of fine steel blocks, or puncheons, of divers sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tops of these blocks, directly under the lines or parts of the figures; then with a fine hammer, striking on the metal, sustained by the block, the metal yields and the block makes an indenture or cavity on the inside, corresponding to which there is a prominence on the outside, which is to stand for that part of the figure.

Thus the workman proceeds to chase and finish all the parts by successive applications of the block and hammer, to the several parts of the design.

ENCHELIS, in natural history, a genus of the Vermes Infusoria. Worm invisible to the naked eye, very simple, cylindrical. There are fifteen species. An account of these may be found in Adams, "On the Microscope."

ENCROACHMENT, in law, an unlawful gaining upon the rights or possessions of another. It is generally applied to the unlawful occupation of wastes and commons.

ENDEMIC, or *endemical-diseases*, those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living.

ENDIVE, in botany, &c. broad-leaved succory.

ENDOWMENT, in law, is the widow's portion, being a third part of all the freehold lands and tenements, of which her husband was seized at any time during the coverture.

ENEMY, in law, an alien or foreigner, who in a public capacity invades any country, and who cannot be punished as a traitor, but must be subjected to martial law.

ENFRANCHISEMENT, in law, the incorporating a person into any society or body politic; such as the enfranchisemen of one made a citizen of London or other city, or burgess of any town corporate, because he is made partaker of its liberties, or franchises.

ENGINE, in mechanics, is a compound machine, consisting of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. See MECHANICS.

Engines are extremely numerous; some used in war, as the battering-ram, balista, waggons, chariots, &c.; others in trade and manufactures, as cranes, mills, presses, &c.; See MECHANICS, HYDROSTATICS, STEAM-ENGINE, &c.

ENGINEER, a term applied to designate a part of the artillery. Their office is to contrive attacks at sieges, and to defend towns when besieged. Engineers have the entire construction and disposition of all forts, redoubts, batteries, mines, &c.: the fortifying of camps and posts; reconnoitering the enemy's works; taking plans and surveys of a country; discovering the most advantageous methods for marching, retreating, attacking, or defending: building of all fortifications, magazines, and other military erections; they must therefore be men of science, and particularly skilled in mathematics and military architecture.

ENGRAILED, or *ingrailed*, in heraldry, a term derived from the French *grele*, hail; and signifying a thing the hail has fallen upon and broke off the edges, leaving them ragged, or with half-rounds or semicircles struck out of their edges.

ENGRAVING. The term engraving, as used at present, signifies the art of cutting wood, copper, steel, or other substances in lines, so managed as to produce imitations of drawings, paintings, &c. when printed on paper.

This art is said to have been discovered by a goldsmith of Florence named Maso Finigerra, but this can only apply to his having obtained impressions from lines engraved originally without any idea of such a result. The art itself must be of the greatest antiquity, since we find it was used among the Jews in the decorations of the Tabernacle. Bezaleel and Aholiab are mentioned in the Book of Exodus as "*filled with wisdom of art, to work all manner of work with the graver,*" &c.; and it is highly probable that the Israelites obtained this art from the Egyptians.

Of engravings there are different kinds; but that which is performed by the graver is the oldest, and to it in common language, the term *engraving* is often exclusively applied, in contradistinction etching, mezzotinto, or any other method.

The principal instruments used in stroke engraving are, the graver or burin, of which there are various sorts; a scraper, a burnisher, and a cushion for supporting the plate.

The graver is an instrument made of steel, of the form of a quadrangular prism, about one tenth of an inch thick, increasing a little in thickness as it approaches the handle which is made of wood, and nearly of a pear shape with a longitudinal slice cut off, for the purpose of enabling the artist to use it as flat on the plate as his fingers and thumb will permit.

The burnisher is about three inches long its use is to soften any of the lines that may be cut too deep.

The scraper is made of steel also: it is generally about six inches long, tapering to a point, and having three sharp edges. It is used for scraping off the barb that is formed by the action of the graver, and for erasing erroneous lines. To shew the appearance of the work as it proceeds, and to polish off the barb more completely, a roll of felt or woollen

cloth, called a rubber, is used for rubbing the part of the plate with a little oil olive.

The cushion is a leather bag filled with sand, in general about nine inches diameter; it was formerly used for laying the plate upon, to allow it to be readily turned in any direction; but it is now very little used, except by the engravers of writing.

For engraving a series of parallel lines, straight or curved, equidistant, or gradually approximating to each other, such as in the blue parts of a sky, water, machinery, &c. where a smooth tint is required, an apparatus was some years ago invented by the late, and truly ingenious Mr. Wilson Lowery, of London.

It is called the ruling machine; its action is mathematically perfect, and the beauty of the execution is altogther unequalled.

For the purpose of conveying a comprehensive idea of the different branches of this admirable art to the reader, we shall here treat of them separately.

1. *Stroke engraving*, or engraving on copper, in the most limited use of the term. Here the first thing to be done, after the plate is well prepared, is to trace the design intended for engraving accurately on the plate, it is usual to heat the latter sufficiently to melt white wax, with which it must be covered equally, and suffered to cool; the drawing is then copied in outlines with a black-lead pencil on paper, which is laid with the pencilled side upon the wax, and the back rubbed gently with the burnisher, which will transfer the lead to the wax. The design must next be traced with an etching needle through the wax on the copper, when, on wiping it clean, it will exhibit all the outlines ready for the graver.

The table intended for engraving on should be perfectly steady, and the sandbags placed equally firm; in cutting of curved or undulating lines, the graver must be held still, or moved, to suit the turning of the plate with the left hand but when straight lines are intended, the plate is to be held stationary, and the graver urged forward with more or less pressure, according to the thickness of the line. Great care is necessary to carry the hand with such steadiness and skill as to prevent the end of the line from being stronger and deeper than the commencement; and sufficient space must be left between the lines to enable the artist to make those stronger, gradually, which require it.

If any accident should occur by the slipping of the graver beyond the boundary required, or lines are found to be placed erroneously, they are to be effaced by the burnisher, which leaving deep indentings, those must be levelled by the scraper, rubbed with charcoal and water, and finally polished lightly with the burnisher.

As the uninterrupted light of the day causes a glare upon the surface of the copper, hurtful and dazzling to the eyes, it is customary to engrave beneath the shade of silk paper, stretched on a square frame, which is placed reclining towards the room near the sill of a window.

Such are the directions and means to be employed in engraving historical subjects: indeed the graver is equally necessary for the completion of imperfections in etching, to which must be added the use of the dry point in both, for making the faintest shades in the sky, architecture, drapery, water, &c. &c.

2. *Mezzotinto Engraving*, commonly called mezzotinto scraping, differs entirely from the manner above described; this method of producing prints, which resemble drawings in Indian ink, was some years past a very favourite way of engraving portraits and historical subjects; of the former, the large heads by Fry are of superior excellence.

The tools required for this mode of proceeding, are the grounding-tool, the scraper, and the burnisher; the copper-plate should be prepared as if intended for the graver, and laid flat upon a table, with a piece of flannel spread under it to prevent the plate from slipping; the grounding-tool is then held perpendicularly on it, and rocked with moderate pressure backwards and forwards, till the teeth of the tool have equally and regularly marked the copper from side to side; the operation is afterwards repeated from end to end, and from each corner to the opposite; but the tool must never be permitted to cut twice in the same place; by this means the surface is converted into a rough chaos of intersections, which, if covered with ink and printed, would present a perfectly black impression upon the paper.

To transfer the design to be scraped, it is usual to rub the rough side of the plate with a rag dipped into the scrapings of black chalk, or to smoke it with burning wax taper, as in the process for etching; the back of the design is then covered with a mixture of powdered red chalk and flake white, and laid on the plate through which it is traced; particles of red, in the form of the outlines, are thus conveyed to the black chalk on the plate, which are to be secured there by the marks of a blunted point; the process must then be carried on with the scraper, by restoring the plate in the perfectly light parts of the intended print to a smooth surface, from which the gradations are preserved by scraping off more or less of the rough ground; but the burnisher is necessary to polish the extreme edges of drapery, &c., where the free touch of the brush in painting represents a brilliant spot of light. The deepest shades are sometimes etched and corroded by aqua fortis, and so blended with the mezzotinto ground added afterwards, that there is nothing offensive to the eye in the combination.

Many proofs are required to ascertain whether the scraping approaches the desired effect, which is done by touching the deficient parts with white or black chalk, on one of the proofs from the original drawing, and then endeavouring to make the plate similar by further scraping, or re-laying the ground with a small tool made for this particular purpose, where too much of the roughness has been effaced.

3. **Etching.** This is an expeditious method of engraving, and when well executed, has a remarkably bold and pleasing effect. The process is this. The plate being prepared as for engraving, is completely covered over with a ground capable of resisting the action of aqua fortis. The design is made with a black-lead pencil on a piece of paper of the same size, which, being moistened in water, and laid on the plate with its face next the etching

ground, and run through the rolling press, leaves a distinct impression on it, which is partially transferred from the paper. The process of using the needle now takes place, in which nothing more is required than to keep it upright, that the lines made by it through the ground may not slope, which would cause the acid to corrode in an improper direction. Great care is necessary to keep the point in such a state of fineness as to prevent its tearing the copper, which would ruin the design.

When the etching of the plate is completely finished, the edges of it must be surrounded by a high border of wax, so well secured that water will not penetrate between the plate and it. The best spirits of nitre fortis must then be diluted with water, in the proportion of one part of the former to four of the latter, which will be found to answer the first operations, if the weather is fine and the atmosphere free from moisture; but, if the contrary is the case, the spirits of nitre must be increased in proportion to the humidity of the air; this, when poured on the plate, cannot be too attentively observed in order to remove the bubbles of fixed air with a feather, and to ascertain the time for stopping out the lightest parts; for it must be remembered the whole secret of biting or corroding any subject consists in the judicious manner in which the depth and breadth of the lines are varied, as by proper management they may be left scarcely perceptible, or increased very considerably. The composition used for the above purpose is, turpentine varnish mixed with lamb-black, and diluted so as to be used freely with a camel's hair pencil; this applied to the parts of the plate sufficiently corroded, will effectually prevent the aqua fortis from touching it again, and the remainder proceeds as if no such application had taken place: it will be necessary to strengthen the water as the work becomes nearer completion, but cautiously, lest the ground should be broken; and every time the aqua fortis is removed the plate must be washed with clean water and gradually dried, otherwise the varnish cannot be used, and the lines would be clogged with the decomposed metal. For taking the ground from the plate it is usual to cover the surface with olive oil, and heating it. wipe the plate with a soft piece of old linen and spirits of turpentine, will effectually remove all remaining dirt.

Etching with what is termed the *dry point* is effected without laying any ground on the plate, simply by the point of the needle; and the barb which is raised by the operation is taken off by the scraper.

4. *Aquatinta Engraving*, or what is by some called the *soft ground*, is a method of making imitations of black-lead or chalk drawings This species of engraving is soft and pleasing, and is well adapted for all picturesque scenery. It is also recommended for the ease with which it is performed.

The principal upon which aquatinta engraving is performed may be thus described. The copper-plate being prepared in the usual manner, is sprinkled over with a resinous powder; the plate being warm the resin adheres in a granulated form to the plate. The nitric acid is then poured on, and immediately attacks the copper, corroding it in all the innumerable interstices where it was left uncovered by the resin, so that if an impression were taken from the plate, the effect would resemble a wash of Indian ink. The different shades are produced by allowing the acid to act for a longer or a shorter space of time on the copper.

In the common aquatinta process, the plate is covered with the common etching ground, and the outlines of the design are etched in the usual manner. The ground is then removed, and the plate is slightly rubbed with the oil-rubber. It is then dusted over with gum copal reduced to a fine powder; the copal must be tied up in a muslin bag, and caused to fall from some height above the plate, by striking the hand in which it is held against a ruler or some other substance held in the other hand, till the shower of dust thus produced has covered the surface of the plate equally throughout. Preserving it carefully in this situation the plate must be warmed sufficiently to melt the powder, which will cause the grains to assume a globular form, and contract, leaving, when cold, a beautiful surface fit for the action of the acid. Common resin is generally preferred for this part of the operation; but gum-copal is less liable to be broken loose from the plate during the process of biting.

The drawing to be copied must serve as the future basis of proceeding, which is to be imitated in the following manner: the perfectly white parts of the intended print are to be covered on the plate, with the varnish mentioned in etching, by the use of a camel's-hair pencil; a border of wax must then be raised, and the aqua fortis diluted poured on; the same method is afterwards practised in the stopping out before recommended, except that the depth of the corroding cannot be so great as in the line manner.

In order to obviate any difficulties which occur in procuring sufficient depths of shade, a method has been invented that enables the artist to produce an effect almost equal to the decisive touches of a brush filled with colour in drawing, which is the use of a liquid made with water, treacle, or sugar, and fine washed whiting, exactly of the consistence of Indian ink, and laid on the granulated surface with a pencil, in the same free manner adopted on paper; after the above composition is thoroughly dry, the whole plate must be covered with a thin, weak, varnish of mastich, turpentine, or asphaltum, and when dried a second time, the aqua fortis is to be applied, which immediately breaking the varnish and whiting, will corrode the plate precisely in the marks of the pencil. The border of wax may be removed by heating the plate gently, and the ground varnish, &c. by oil of turpentine; a little fine whiting and a clean rag will then render the plate fit for the printer.

Such is the common method of engraving in aquatinta; but there are other methods adopted by modern artists, which are much superior, but which they have not yet thought proper to make public.

5. *Stippling*, or the chalk manner is also performed upon the etching ground, by dots instead of lines made with the etching needle This beautiful effect is produced by a wheel, consisting of many points diverging from its centre, and revolving on its centre This instrument is moved forwards and backwards

on the plate, its motions being regulated by the skill of the artist, until it has sufficiently marked the copper, producing an excellent imitation of chalk-drawing; the work is then bitten with acid in the usual way. Ryland and Bartalozzi were the most distinguished in this art

6. *Engraving on Wood.* Engraving on wood is a process exactly the reverse to engraving on copper. In the latter, the strokes to be printed are sunk, or cut into the co and a rolling-press is used for printing it; but in engraving on wood, all the wood is cut away, except the lines to be printed, which are left standing up like types, and the mode of printing is the same as that used in letter-press.

The wood used for this purpose is box wood, which is planed quite smooth. The design is then drawn upon the wood itself with black lead; and all the wood is cut away with gravers and other proper tools, except the lines that are drawn: or sometimes the design is drawn upon paper, and pasted upon the wood, which is cut as before. The art is of considerable difficulty, and there are very few who practise it. It is, however, useful for books, as the printing of it is cheaper than that of copper-plates. It cannot be applied equally well to all the purposes to which copper-plate engraving is applicable.

7. *Engraving on stone,* is a method of imitating pen and ink drawings, for which the inventor some years ago obtained a patent. It is performed on a slab of close-grained stone.

The design is made out with a pen, dipped in a solution of lac, in the ley of pure soda, with a little soap, and coloured with lamp black. When the drawing has been on the stone for three or four days, or when the ink is perfectly dry, it is soaked in water. While wet, it is daubed with printers' ink, and the ink adheres to the design and not to the stone. The impression is then taken from it in the same way as letter-press printing, by putting a sheet of damp paper over it, and subjecting it to the action of the press.

This method of engraving is called *lithography*, and, although only a modern invention, it has already been carried to great perfection.

Another method is, to take calcareous stone or slab of marble, with a good polish, of about two or three inches in thickness, and of a size proportioned to that of the design to be executed on it. The design, whatever it may be, is marked out with a solution of gum lac and pot-ash, coloured with lamp black. When it is dry, the stone is covered with aqua-fortis, which, attacking all parts of the stone except those impregnated with the resinous acid, the drawing remains untouched, and [illegible]ears like the block of a woodcut.

After the acid has bitten sufficiently deep, the slab must be washed with clean water, and while wet, printing ink is applied to it in the usual way, and it is put through the press.

After each impression the block must be washed with water. This method, for expedition, cheapness, and durability, has decidedly the advantage over the usual process, particularly for music; it is said that at the Stone Printing Office at Vienna, thirty thousand im- were taken off the same slab, the last impression being nearly as good as the first.

8. *Engraving on steel.* This is principally employed for cutting signets, matrices, punches, and dies for striking coins and medals. The engraving of the device on the punches is performed in relievo, after a wax model; and when finished, it is tempered so as to stand the strokes of the hammer in striking in the impression on the matrix. The steel of the die is made soft by heat, that it may take the impression of the punch; and when struck, is touched up by graving tools, chisels, &c. where there are any deficiencies.

Etching on steel is effected by drawing the design with Brunswick black, laid on with a hair pencil. It is then bedded in glaziers' putty, or the bordering wax used for etching, and the aqua-fortis poured over it, and suffered to remain till it be bitten to the requisite depth. It is then poured off, and the black cleaned away with a little turpentine.

9. *Etching on glass.* This is done by laying on a ground consisting of a thin coat of bees wax, and making out the design with an etching needle. The glass plate is then placed in a leaden vessel and exposed to the action of the fumes of fluoric acid. In the course of a few hours it may be removed, and the parts of the glass that were laid bare will be found to be corroded. The plate being cleaned with some oil of turpentine, impressions may be taken from it in the usual way. This method is used for ornamenting vessels of glass instead of grinding.

10. *Seal Engraving.* The art of seal engraving appears to be of great antiquity; it is performed both in cameo and intaglio, and extends to all kinds of precious stones. The operation is performed by inserting the tools into the axis of a small iron-wheel, which is attached to an apparatus resembling a turning lathe, and kept in motion by the foot. The tools are tightened by a screw, and the stone to be engraved is held by the hand to the tool as it revolves, and is conducted as the nature of the figure requires.

The tools are generally made of iron, and are of various forms, as chisels, gouges, &c.

ENMANCHE, in heraldry, is when lines are drawn from the centre of the upper edge of the chief to the sides, to about half the breadth of the chief; signifying sleeved, or resembling a sleeve.

ENNEANDRIA, in botany, the ninth class of plants with hermaphrodite flowers, and nine stamina or male parts in each. See BOTANY. To this class belong the laurus, rheum, spondias, butomus, &c.

ENSIFORM, in general, something resembling a sword, ensis: thus we find mention of ensiform leaves, ensiform cartilage, &c.

ENSIGN, in the military art, a banner under which the soldiers are ranged according to the different companies or parties they belong to.

ENSIGN is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordinate to the captain and lieutenant.

ENTABLATURE, or *entablement*, in architecture, is that part of an order of a co

lumn which is over the capital, and comprehends the architrave, frieze, and cornice.

Entablature, in masonry, is used sometimes to denote the last row of stones on the top of the wall of a building, on which the timber and covering rest.

ENTAIL, in law, is a fee-estate entailed; that is, abridged and limited to certain conditions prescribed by the donor or grantor.

ENTOMOLOGY from *εντομα an insect* and λογος *a discourse*, is the science which treats of insects. As animals of this class constitute the most considerable portion of animated beings, entomology becomes one of the most interesting and important sciences which can engage the mind of the philosopher; and one which affords the most ample scope for his zeal. From the narrowness of our limits we can here offer only a few general remarks on the subject and put the reader in possession of the classification of insects as given by Linnæus.

Insects are distinguished from other animals by their being furnished with several feet; never fewer than six, and sometimes with many more; by their breathing, not through lungs, but by spiracles or breathing-holes, situated at certain distances along each side of the body; and lastly, by the head being furnished with a pair of *antennæ*, or jointed horns, which are extremely various in the different tribes. The first state in which the generality of insects appear, is that of an *egg*. From this is hatched the animal in its second state, in which it is often but improperly called the *caterpillar*. The insect, in this state, is the *larva* or larve, being a mask or disguise of the animal in its future form. The larve differs in its appearance, according to the tribe to which it belongs. When the time arrives for the larve to change into its next state of *chrysalis*, or *pupa*, it ceases to feed, and having placed itself in some quiet situation, for the purpose, lies still for several hours; and then, by a kind of laborious effort, frequently repeated, divests itself of its external skin, or larve-coat, and immediately appears in the very different form of a pupa. The pupa emerges at length the complete insect, in its perfect or ultimate form, from which it never can after change, nor can it receive any further increase of growth. This last or perfect state is termed the *imago*.

Some insects undergo a change of shape, but are hatched from the egg complete, in all their parts, and only cast their skin from time to time, during their growth, till they acquire the full size of their respective species. The *mouth*, in some tribes, is formed for gnawing or breaking the food, and operates by a pair of strong horny jaws, moving laterally, as in the beetle tribe; while in others, it is formed for suction, and consists of a sort of tube. In the butterfly, and moth tribe, it consists of a double tube, which, when at rest, is rolled into a spiral form, and extended at full length when in use. The *eyes* differ in the different tribes, but by far the greater part of insects are furnished with eyes apparently two in number, and situated on each side the head. The outward surface of the coats of these eyes may be compared to so many convex lenses or glasses. The head of the *libellula*, or common dragon-fly, is furnished with 25,000 of these diminutive lenses! In *spiders*, the eyes are from six to eight in number; of a simple structure, and placed at a considerable distance from each other.

3. The *muscles*, or organs, constituting the several portions of the flesh in insects, are far more numerous than in the larger animals, and are extremely sensible or irritable. In the human body, the muscles scarcely exceed 500, but in a large caterpillar more than 4000 have been discovered! The power of the muscles is also much greater than in animals. A flea is capable of springing at least 200 times its own length; whereas the jerboa and kangaroo in their most powerful springs, fall very short of the same *proportional* distance. Insects are divided into seven orders: *coleoptera, hemiptera, lepidoptera, neuroptera, hymenoptera, diptera*, and *aptera*.

Order 1. *Coleoptera*, or insects which have a hollow horny case, under which the wings are folded, when not in use. The genera are: 1. *Scarabæus*, beetles. 2. *Lucanus*, stag-beetle. 3. *Dermestes*. 4. *Coccinella*, lady-bird. 5. *Curculio*, weevil. 6. *Lampyris*, glow-worm. 7. *Meloe*, spanish fly. 8. *Staphylinus*. 9. *Forficula*, ear-wig.

Order 2. *Hemiptera*, or half winged insects. In this order, the wing-sheaths are tough or leathery at their upper part, and soft or membranaceous at the lower, and the real or under-wings are often of great size, and placed longitudinally in the manner of a fan. The genera are: 1. *Blatta*, cock-roach. 2. *Gryllus*, locust, grass-hopper. 3. *Fulgora*, lantern-fly. 4. *Cimex* bug, &c.

Order 3. *Lepidoptera*, or scaly winged insects. The powder, or down on the wings of these insects, has been considered as composed of a kind of feathers; but, in reality, it is composed of a kind of very minute scales, which differ in size and form in the different species, as well as on different parts of the same species. The genera are: 1. *Papilio*, butter-fly. 2, 3. *Sphinx* and *Phalæna*, moths.

Order 4. *Neuroptera*, or nerve-winged, or fibre-winged insects. This order consists of such as have four large wings, furnished with very conspicuous nerves, fibres, or ramifications dispersed over the whole wing. The genera are: 1. *Libellula*, dragon-fly. 2. *Ephemera*, may-fly, or trout-fly, &c.

Order 5. *Hymenoptera*, or insects having four wings, but not fibrous like the former order. They generally possess a sting or piercer which in some is innocent; but in others, it is calculated for the discharge of a highly acrimonious or poisonous juice, as in wasps and bees.

The genera are: 1. *Vespa*, wasp, hornet. 2. *Apis*, bee. 3. *Formica*, ant. 4. *Termes*, white ant. 5. *Ichneumon*, &c.

Orde[illegible] *Diptera*, consists of insects with two wi[illegible] only, as the whole race of flies strictly so called as well as gnats, and a great variety of other insects. The genera are: 1. *astrus*, gad-fly. 2. *Musca*, common flies. 3. *Culex*, gnat, musquito. 4. *Hippobosca*, horse-leech, &c.

Order 7 *Aptera*, or insects without wings. The genera are: 1. *Podura*, spring-sail. 2 *Pediculus*, louse. 3. *Pulex*, flea, chigger. 4 *Acarus*, tick, mite. 5. *Aranea*, spiders. 6. *Scorpio*, scorpion. 7. *Cancer*, crab, lobster craw-fish, shrimp. 8. *Monoculus*, water-flea.

9. *Oniscus*, wood-louse. 10. *Scolopendra*, centipede.

ENTOYER, in heraldry, denotes a bordure charged wholly with things without life: it seems to be a corruption of the French *entour*, round about.

ENTRY, *writ of*, is a writ directed to the sheriff, requiring him to command the tenant of the land, that he render to the demandant the premises in question, or appear in court on such a day, and shew why he has not done it.

ENVELOPE, in fortification, a work of earth, sometimes in form of a simple parapet, and at others, like a small rampart with a parapet; it is raised sometimes on the ditch, and sometimes beyond it.

ENUMERATION, in rhetoric, a part of the peroration, in which the orator, collecting the scattered heads of what has been delivered throughout the whole, makes a brief and artful relation, or recapitulation of it.

ENVOY, a person deputed to negociate some affair with any foreign prince or state. Those sent from the courts of France, Britain, Spain, &c. to any petty prince or state, such as the princes of Germany, the republics of Venice, Genoa, &c.

EPACRIS, in botany, a genus of the monogynia order, in the pentandria class of plants. There are four species, natives of New Holland.

EPACT, in chronology, a number arising from the excess of the common solar year above the lunar, by which the age of the moon may be found every year.

The excess of the solar year above the lunar is 11 days; or the epact of any year expresses the number of days from the last new moon of the old year, which was the beginning of the present lunar year, to the 1st of January. On the first year of the cycle of the moon, the epact is 0, because the lunar year begins with the solar. On the second, the lunar year has begun 11 days before the solar year, therefore the epact is 11. On the third, it has begun twice 11 before the solar year, therefore the epact is 22. On the fourth it begins three times 11 days sooner than the solar year, the epact would therefore be 33; but 30 days being a synodical month, must that year be intercalated; or that year must be reckoned to consist of 13 synodical months, and there remain three, which is the true epact of the year; and so on to the end of the cycle, adding 11 to the epact of the last year, and always rejecting 30, gives the epact of the present year. Thus, to adjust the lunar year to the solar, through the whole of 19 years, 12 of them must consist of 12 synodical months each, and 7 of 13, by adding a month of 30 days to every year when the epact would exceed 30, and a month of 29 days to the last year of the cycle, which makes in all 209 days, *i. e.* 19 × 11; so that the intercalary or embolimæan years in this cycle are 4, 7, 10, 12, 15, 18, 19.

EPAULEMENT, in fortification, a work raised to cover sidewise, is either of earth, gabions, or fascines, loaded with earth. The epaulements of the places of arms for the cavalry, at the entrance of the trenches, are generally of fascines mixed with earth.

EPHEDRA, in botany, a genus of the monodelphia order, in the diœcia class of plants and in the natural method ranking under the 51st order, coniferæ. There are two species, shrubs of Siberia.

EPHEMERA, the *day-fly*, or *May-fly*, in zoology, a genus belonging to the order of neuroptera. There are 11 species. These flies take their name of May-fly from the shortness of their life, and are distinguished into several species. Some live several days; others do not take flight till the setting of the sun, and do not even live to see him rise. Some exist but one hour, others but half that time. With respect to those that live several days, Mr. Barbut observes, there is a peculiarity incident to them. They have to cast off one slough more, an operation which sometimes takes 24 hours to complete. To effect this they cling fast to a tree. The ephemeræ, before they flutter in the air, have in some manner been fishes. They remain in the states of larva and chrysalis for one, two, or three years. The chrysalis only differs from the larva by there being observable on its back cases for wings. Both have on their sides small fringes of hair, which, when put into motion, serve them as fins. Nothing can be more curious than the plying of those little oars in the water. The abdomen is terminated, as well as in their state of flies, by three threads. These larvæ scoop themselves out dwellings in the banks of rivers; and they are small tubes made like siphons, the one serving for an entrance, the other affording them an outlet. The banks of some rivers are often perforated with them. When the waters decrease, they dig fresh holes lower down, in order to enjoy the water. The season and hour when the chrysalis of the different species of the ephemeræ turn into flies, maintain a kind of regularity. The heat, the rise or fall of the waters, accelerate, however, or postpone their final display. The ephemeræ of the Rhine appear in the air two hours before sunset. These flies are hatched almost all at the same instant in such numbers as to darken the air. The females, by the help of the threads of their tail and the flapping of their wings, support themselves on the surface of the water, and in that situation they drop their eggs in clusters. One female will lay 700 or 800 eggs, which sink to the bottom. The larvæ that escape the fish, set about the construction of habitations to shelter them from danger. When the flies have propagated, they are seen to die, and fall by heaps.

Ephemera, in medicine, the name of a species of fever continuing the space of one day, or sometimes more.

EPHEMERIDES, in astronomy, tables shewing the present state of the heavens for every day at noon; that is, the places wherein all the planets are found at that time. It is from these tables that the eclipses, conjunctions, and aspects of the planets, are determined; and horoscopes or celestial schemes constructed.

EPHIELIS, a genus of the class and order octandria monogynia. The calyx is five parted; petals five-clawed; nect. ten scales; capsule oblong. There is one species, a tree of Guiana.

EPIC, or *heroic poem*, a poem expressed in narration, formed upon a story partly real and partly feigned; representing in a sublime style, some signal and fortunate action, distinguished by a variety of great events, to form the

morals, and affect the mind with the love of heroic virtue.

EPICYCLOID, in geometry, a curve generated by the revolution of the periphery of a circle, along the convex or concave side of the periphery of another circle.

EPIDEMIC, in medicine, denotes those diseases which prevail at particular seasons, attacking many persons at the same time.

EPIDENDRUM, a genus of the diandria order, in the gynandria class of plants, and in the natural method ranking under the 7th order, orchideæ. There are 124 species, one of which is the plant which produces the fruit called vanilla, used in the making of chocolate. It is a native of Mexico, and also of some parts of the East Indies. The flowers are white, intermixed with stripes of red and yellow. When these fall off they are succeeded by the pods, which at first are green, but afterwards become yellow, and are gathered for use. The pods of the best vanilla are long, slender, and filled with seeds. If opened when fresh, the cavity is found to contain a humid substance, black, and balsamic, of such a strong smell, that it frequently causes headaches, and even intoxication.

EPIDERMIS, in anatomy, is the cutical or scarf skin.

EPIGRAM, a short poem, treating only of one thing, and ending with some lively, and natural thought, or point.

EPIGRAPHE among antiquarians, denotes the inscription on a building, pointing out the time when, the persons by whom, and the uses, for which it was erected.

EPILEPSY, in medicine, the same with what is otherwise called the falling-sickness, from the patient's falling suddenly to the ground.

EPILOBIUM, the *willow-herb*, in botany, a genus of the monogynia order, in the octandria class of plants; and in the natural method ranking under 17th order, calycanthemæ. There are fourteen species, several of them natives of Britain. They grow in marshes, or under hedges in moist and shady places; having blossoms generally of a red colour, and sometimes of considerable beauty. The most remarkable is the hirsutum, commonly called codlins and cream.

EPILOGUE, in dramatic poetry, a speech addressed to the audience after the play is over.

EPIMEDIUM, *barren-wort*, in botany, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 24th order, corydales. There is only one species, viz. the alpinum. It is a low herbaceous plant, with a creeping root.

EPISODE, in poetry, a separate incident, story, or action, which a poet invents and connects with his principal action, that his work may abound with a greater diversity of events.

EPITAPH, a monumental inscription in honour or memory of a person defunct, or an inscription engraven or cut on a tomb, to mark the time of a person's decease, his name, family, and, usually, some eulogium of his virtues, or good qualities.

EPITHALAMIUM, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

EPITHET, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration.

EPOCHA, in chronology, a term or fixed point of time, whence the succeeding years are numbered or accounted. See CHRONOLOGY.

EPODE, in lyric poetry, the third or last part of the ode, the ancient ode being divided into strophe, antistrophe, and epode.

EPOPOEIA, in poetry, the story, fable, or subject treated of, in an epic poem. The word is commonly used for the epic poem itself.

EPSOM *salt*, another name for sulphate of magnesia.

EQUABLE, an appellation given to such motions as always continue the same in degree of velocity, without being either accelerated or retarded.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality. Mathematicians speak of equal lines, angles, figures, circles, ratios, solids, &c.

EQUALITY, that agreement between two or more things whereby they are denominated equal. The equality of two quantities, in algebra, is denoted by two parallel lines placed between them: thus, $4+2=6$, that is, 4 added to 2 is equal to 6.

EQUANIMITY, in ethics, denotes that even and calm frame of mind and temper under good or bad fortune, whereby a man appears to be neither puffed up or overjoyed with prosperity, nor dispirited, soured, or rendered uneasy by adversity.

EQUATION. See ALGEBRA.

EQUATION, *of a curve*, an equation expressing the nature of a curve, the relation between an abscis and a corresponding ordinate, or the relation of their fluxions. See CURVE.

EQUATION *of time*, in astronomy and chronology, the reduction of the apparent time or motion of the sun, to equable, mean, or true time. See ASTRONOMY.

EQUATOR, in geography, a great circle of the terrestrial globe, equidistant from its poles, and dividing it into two equal hemispheres; one north and the other south. See GLOBES, *use of*.

EQUATORIAL, *universal*, or PORTABLE OBSERVATORY, is an instrument intended to answer a number of useful purposes in practical astronomy independent of any particular observatory. It may be employed in any steady room or place, and it performs most of the useful problems in the science of astronomy.

EQUERRY, in the British customs, an officer of state under the master of the horse. There are five equerries, who ride abroad with his majesty; for which purpose they give their attendance monthly, one at a time, and are allowed a table.

EQUES *auratus*, is used for a knight bachelor, called *auratus*, q. d. *gilt*, because anciently none but knights were allowed to beautify their armour, or other habiliments of war, with gold.

EQUESTRIAN *statue*, signifies the statue of a person mounted on horseback.

EQUESTRIAN *order*, among the Romans, signified their knights or equites, as also their troopers or horsemen in the field; the first of which orders stood in contradistinction to the senators, as the last did to the foot, military, or infantry: each of these distinctions was introduced into the state by Romulus.

EQUIANGULAR, in geometry, an epithet given to figures whose angles are all equal: such are a square, an equilateral triangle, &c.

EQUIDIFFERENT *numbers*, in arithmetic, are of two kinds. 1. Continually equidifferent is when, in a series of three numbers, there is the same difference between the first and second, as there is between the second and third; as 3, 6, 9. And 2. Discretely equidifferent is when, in a series of four numbers or quantities, there is the same difference between the first and second, as there is between the third and fourth: such are 3, 6, 7, 10.

EQUIDISTANT, an appellation given to things placed at an equal distance from some fixed point, or place, to which they are referred.

EQUILATERAL, in general, something that has equal sides, as an equilateral triangle.

EQUILIBRIUM, in mechanics, is when the two ends of a lever or balance hang so exactly even and level, as neither to ascend nor descend, but keep in a position parallel to the horizon; which is occasioned by their being both charged with an equal weight.

EQUIMULTIPLES, in arithmetic and geometry, are numbers of quantities multiplied by one and the same number or quantity. Hence, equimultiples are always in the same ratio to each other, as the simple quantities before multiplication.

EQUINOCTIAL, in astronomy, a great circle of the celestial globe, whose poles are the poles of the world. It is so called, because whenever the sun comes to this circle, the days and nights are equal all over the globe; being the same with that which the sun seems to describe, at the time of the two equinoxes of spring and autumn. All stars directly under this circle, have no declination, and always rise due east, and set full west. The hour circles are drawn at right angles to it, passing through every fifteenth degree; and the parallels to it are called parallels of declination.

EQUINOX, the time when the sun enters either of the equinoctial points, where the ecliptic intersects the equinoctial. It was evidently an important problem in practical astronomy, to determine the exact moment of the sun's occupying these stations; for it was natural to complete the course of the year from that moment. Accordingly this has been the leading problem in the astronomy of all nations. It is susceptible of considerable precision without the use of instruments. It is only necessary to observe the sun's declination on the noon of two or three days before and after the equinoctial day. On two consecutive days of this number, his declination must have changed from north to south, or from south to north. If his declination on one day was observed to be 21, north, and on the next 5, south, it follows that his declination was nothing, or that he was in the equinoctial point about 23 minutes after 7 in the morning of the second day. Knowing the precise moments, and knowing the rate of the sun's motion in the ecliptic, it is easy to ascertain the precise point of the ecliptic in which the equator intersected it. By a series of such observations made at Alexandria, between the years 161 and 127 before Christ, Hipparchus found that the point of the autumnal equinox was about six degrees to the eastward of the star called spica virginis. Eager to determine every thing by multiplied observations, he ransacked all the Chaldean, Egyptian, and other records, to which his travels could procure him access, for observations of the same kind; but he does not mention his having found any. He found, however, some observations of Aristillus and Timochares, made about 150 years before. From these it appeared evident that the point of the autumnal equinox was then about eight degrees east of the same star. He discusses these observations with great sagacity and rigour: and on their authority, he asserts that the equinoctial points are not fixed in the heavens, but move to the westward about a degree in 75 years.

This motion is called the precession of the equinoxes, because by it the time and place of the sun's equinoctial station precedes the usual calculations: It is fully confirmed by all subsequent observations. In 1750, the autumnal equinox was observed to be 20° 21′ westward of spica virginis. Supposing the motion to have been unform during this period of ages, it follows that the annual precession is about *$50\frac{1}{4}$*; that is, if the celestial equator cuts the ecliptic in a particular point on any day of this year, it will on the same day of the following year, cut it in a point $50\frac{1}{4}$° to the west of it, and the sun will come to the equinox 20′ 23″ before he has completed his round of the heavens. Thus the equinoctial, or tropical year, or true year of seasons, is so much shorter than the revolution of the sun or the sidereal year. It is this discovery that has chiefly immortalized the name of Hipparchus, though it must be acknowledged that all his astronomical researches have been conducted with the same sagacity and intelligence.

EQUULEUS, in astronomy, a constellation of the northern hemisphere, whose stars, according to Ptolemy and Tycho's catalogues, are four, but in Mr. Flamsteed's ten.

EQUUS, the horse, a genus of the mammalia class, of the order of belluæ. The generic character is, front teeth in the upper jaw six, parallel; in the lower jaw six, somewhat projecting; canine teeth, one on each side, in both jaws, remote from the rest; feet with undivided hoofs.

1. Equus caballus, or the common horse, the most noble and interesting of quadrupeds, is supposed to be found in a state of nature in several parts of Asia and Africa. In this state it is smaller than the domestic or tame animal, with a larger head, a more arched forehead, and the body thickly covered with pale-brown, or mouse-coloured hair.

Large herds of wild horses are said to be found about the lake Aral, near Kusneck, in lat. 54°; on the river Tom, in the southern parts of Siberia, and among the Kalkas, north-west of China. They are extremely swift, active, and vigilant; and, like some of the antelopes and other quadrupeds, have always a

sentinel, who gives notice to the herd on the approach of danger by a loud neigh; upon which they fly off with amazing rapidity.

Wild horses are found, according to Dr. Pallas, in the deserts on each side the river Don, towards the Palus Mæotis; but these are supposed to be the offspring of the Russian horses, which were employed in the siege of Asoph, in the year 1697, when for want of forage they were turned loose, and their descendants have gradually relapsed into the appearance of natural wildness.

The horse, in its domestic or improved state, is found in almost every part of the world, except perhaps within the Arctic circle; and its reduction and conquest may well be considered, as Buffon properly observes, as the greatest acquisition from the animal world ever made by the art and industry of men.

But no country has produced a breed of horses equal in size and strength to the larger kind of our draught horses. The cavalry of England is, in general, formed of this class of horses. The fens of Lincolnshire generally produce a larger breed than any other part of the kingdom. In our own country there seem to be no breed of horses naturally of a perfect white; those which are so termed having been first grey, changed through age to whiteness.

The most beautiful general colour seems to be bright bay, which gives an air of peculiar neatness and elegance to the animal. Black horses are commonly of large size, and in this country are chiefly used for the cart and the plough.

2. *Equus hemionus*, or jicta. This is a native of the desert regions between the rivers Onon and Argun, in the most southern parts of Siberia; and extends over the vast plains and deserts of Tartary, as well as that of Gobi, which reaches even to India. It shuns wooded and mountainous regions, and is said to live in small herds of about twenty each. Its general manners are those of the common wild horse; but its swiftness is still greater than that of the antelope.

This animal has an appearance much resembling that of a common mule; having a large head, flat forehead, middle-sized eyes, with ash-coloured irides; the ears are larger than in that species, erect, and lined with a thick, whitish, curling hair: the neck is slender and compressed: the mane upright, short, soft, and of a greyish colour. The winter coat of this animal is of a brownish ash-colour, with the tips of the hair grey. In summer it becomes much smoother, and in all parts elegantly marked by small featherings. The length of this species, from nose to tail, is about six feet and a half; that of the trunk of the tail sixteen inches.

3. *Equus asinus*, the ass. The ass, having been long condemned to a state of the lowest servitude, and considered as a species of less dignity than the horse, has acquired, in most parts of Europe, a character of contempt. Yet in its natural or wild state it exhibits an appearance very far superior both in point of beauty and vivacity. It is said to be found in Africa, and to occur, though but very rarely, in some parts of Syria and Arabia; countries where it was in ancient times extremely common. In its natural state its colour is said to be white, or a very pale silvery grey, with a slight tinge of straw-colour on the sides of the neck and body: along the back runs a deep-brown stripe of thickish wavy hair, to the beginning of the tail: this stripe is crossed over the shoulders, as in the tame animal, by another of similar colour; but it is said that this is peculiar to the male.

The food of the wild ass consists chiefly of saline, or bitter and lactescent plants. It is also fond of salt or brackish water. The manners of these animals very much resemble those of the wild horse. They assemble in troops, under the conduct of a leader or sentinel; and are extremely shy and vigilant, and dart off with the utmost rapidity on the sight of mankind. They have been at all times celebrated for their swiftness.

From this animal the domestic ass has been derived, which admits of considerable varieties. Those of the eastern parts of the world, as well as those of Africa, still partake, in a great degree, of the native elegance of their original or stock; and are very different from those commonly seen in the northern parts of Europe: for this animal seems to be much injured by the influence of a comparatively cold climate.

It may not be improper to observe, that the mule is nothing more than a hybrid animal, betweeen this species and the horse, differing in strength, size, and beauty, according to the predominacy of its parental species. Mules are very little used in this country, but in Spain and some other parts of Europe are in much esteem, and have deservedly the reputation of being remarkably sure footed.

4. *Equus zebra*, or the zebra, is a native of the hotter parts of Africa, being found from Æthiopia to the Cape of Good Hope, living in large herds, and possessing much of the manners both of the wild horse and the ass, being excessively swift and vigilant. It is of a still wilder or more unmanageable disposition than either of the former animals, and even such as have been taken very young are with much difficulty brought to any degree of familiarity, and have very rarely been rendered so far manageable as to submit to the bridle.

The size of the zebra is equal, or rather superior, to that of the ass, and its form more elegant; since, exclusive of its beautiful colours, the head and ears are well shaped, and of moderate size. The colour is either milk-white, or cream-colour, with a very slight cast of buff or pale ferruginous; and the whole animal is decorated on every part with very numerous black or blackish-brown stripes, disposed with the utmost symmetry, and exhibiting an appearance not easily described in words.

5. *Equus quagga*, or the quagga, which till lately was confounded with the zebra, is now acknowledged as a distinct species, much allied to the former, but marked with fewer and larger bands, which are of a browner colour than in the zebra, and are chiefly disposed on the fore parts of the animal, while the hind parts are rather spotted than striped. The ground-colour also of the quagga is of a ferruginous tinge, especially on the thighs and back. It is of a milder or more docile nature than the zebra, and is said to have been successfully used by some of the Dutch colonists at the Cape, in the manner of a horse, for draught, &c.

6. *Equus bisculus*, or cloven footed horse

The very name of this species seems to imply a kind of equivocal and anomalous being, one of the most prominent characters of the present genus being a simple or undivided hoof. It is very wild, strong, and swift and is found in the rocky regions of the Andes or Cordilleras of Peru and Chili. The hoofs are divided like those of ruminant animals.

ERANTHEMUM, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking with those of which the order is doubtful.

There are five species, herbs or under-shrubs of the Cape of Good Hope.

ERICA, *heath*, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 18th order, bicornes. There are upwards of 100 species, four of them natives of Britain, which are so well known, that no description need be given of them. In the Highlands of Scotland this plant is made subservient to a great variety of purposes. The poorer inhabitants make walls for their cottages with alternate layers of heath and a kind of mortar made of black earth and straw. They make their beds of it, by placing the roots downwards; the tops being sufficiently soft to sleep upon. Cabins are also thatched with it. In the island of Ilay, ale is frequently made by brewing one part of malt and two of the tops of young heath, sometimes adding hops. Woollen cloth boiled in alum-water, and afterwards in a strong decoction of heath-tops, comes out of a fine orange-colour. The stalks and tops will tan leather. Besoms, and faggots to burn in ovens, are also made of this plant. Bees extract a great deal of honey from the flowers; and where heath abounds, the honey has a reddish cast.

ERIDANUS, in astronomy, a constellation of the southern hemisphere, containing, according to different authors, 19, 30, or even 84 stars.

ERIGERON, *flea-bane*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are 30 species, of which the most remarkable is the viscosum. It is a native of the south of France and Italy; and has a perennial root, whence arise many upright stalks near three feet high. The flowers are produced single upon pretty long footstalks, are of a yellow colour, and have an agreeable odour.

ERINACEUS, *hedgehog*, a genus of quadrupeds of the order of feræ.

The species are: 1. *Erinaceus Europæus*, common or European hedgehog. The hedgehog is found in most of the temperate parts of Europe and is also seen in Madagascar. It commonly measures about 11 inches from the nose to the tip of the tail, which is about an inch long. Its colour is generally grey-brown, but it sometimes is found totally white. It feeds principally on the roots of vegetables; but it also eats worms, as well as beetles and other insects. It wanders about chiefly by night, and during the day conceals itself in its hole, under the roots of some tree, or mossy bank. It produces four or five young at a birth, which are soon covered with prickles like those of the parent animal. The nest is large, and is composed of moss.

The hedgehog, when disturbed, rolls itself up into a globular form, and thus presents to its adversary an invulnerable ball of prickles. From this state of security, it is not easily forced; scarce any thing but cold water obliging it to unfold itself. It swims well when thrown into water.

The hedgehog is, during the winter, supposed to continue in a state of torpidity. It may be rendered domestic; and has frequently been introduced into houses for the purpose of expelling the blattæ, or cockroaches, of which it is fond.

2. *Erinaceus inauris*. Earless hedgehog. This, on a general view, seems to be nothing more than a variety of the common hedgehog, differing chiefly, in having the spines on the upper parts of the body shorter, thicker, and stronger; the head shorter, and the snout blunter than in the common hedgehog, and there is no appearance of external ears; the whole animal is also of a white or pale colour. Its length from nose to tail is about eight inches; the tail scarcely an inch long; the claws long and crooked.

3. *Erinaceus auritus*. Long-eared hedgehog. This species resembles the common hedgehog in form, and is found about the river Volga, and in the eastern parts beyond lake Baikal. In its general manner of life this species is said to resemble the common hedgehog. The female produces six or seven young at a time, and is said sometimes to breed twice a year.

4. *Erinaceus Madagascariensis*. Striped hedgehog. This animal, which is a native of Madagascar, is of a black colour, with five longitudinal bands on the body; all the black parts are covered with hard hair; the white bands with small prickles, like those of a porcupine. From the black bands on the back, spring long scattered hairs which reach to the ground; the head is covered with short black hairs or prickles; the snout is white; the eye surrounded by a white circle, and the feet are reddish. They burrow under ground, and live chiefly on fruits and herbs.

5. *Erinaceus Malaccensis*. Malacca hedgehog. This species has completely the appearance of a procupine; but Brisson considered it as a species of hedgehog; and Linnæus, in compliance with his opinion, transferred it from the genus hystrix to that of erinaceus.

ERINUS, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There are 13 species, none of them natives of Britain.

ERIOPHORUM, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the third order, calamariæ. There are six species, nearly allied to the grasses, only two are natives of Britain.

ERITHALIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. There are two species, trees of Jamaica and the Society Isles.

ERMIN. See MUSTELA.

ERMIN, in heraldry, is always argent and sable, that is, a white field, or fur, with black spots.

ERMINE, or *cross ermine*, is one composed of four ermine spots; the colours in these arms are not to be expressed, because neither this cross nor these arms can be of any other colour than white and black.

ERNODIA, a genus of the class and order tetrandria monogynia. There is one species, a creeping plant of Jamaica.

ERODIUM, *crane's bill*, a genus of the class and order monodelphia pentandria, and in the natural method of the other gruinales. This genus is vulgarly confounded with the geranium: indeed there are three genera, which have the same habits, but differing in the number of stamina. This plant has five, the geranium seven, and the pelasconium, or African geranium, ten. Of the erodium there are 28 species including at least three which are natives of Britain.

ERODIUS, a genus of insects of the order of coleoptera. The antennæ are moniliform; feelers, filiform; body roundish, gibbous. immarginate; thorax, transverse; shells closely united, longer than the abdomen; jaw horny, bifid; lip horny, emarginate. There are four species.

EROTEUM, a genus of the class and order pentandria monogynia. There are two species, natives of Jamaica.

ERROR, in law, signifies an error in pleading, or in the process; and the writ which is brought for remedy thereof, is called a *writ of error*

ERUCA, in general, denotes caterpillars of all kinds. The caterpillar state is that through which every butterfly must pass before it arrives at its perfection and beauty. The change from caterpillar to butterfly was long esteemed a real change of one animal into another; but this is by no means the case. The egg of a butterfly produces a butterfly with all the lineaments of its parent; only these are not disclosed at first, but for the greater part of the animal's life they are covered with a sort of case or muscular coat, in which are legs for walking: these only suit it in this state; but its mouth takes in nourishment, which is conveyed to the included animal: and after a proper time this covering is thrown off, and the butterfly, which all the while might be discovered in it by an accurate observer with the help of a microscope, appears in its proper form. Before it passes into this state, however, there requires a state of rest for the wings to harden, and the several other parts to acquire their proper firmness; this is transacted in a time of perfect rest, when the animal lies in what is called the nymph or chrysalis state, in appearance only a lump of inanimate matter. There is a settled and determined time for each of these changes in every species; but in the several different kinds, the periods are different.

There is no sign of sex in the animal while in the caterpillar state: the propagation of the species is the business of the creature in its ultimate perfection; one female butterfly, when she has been impregnated by the male, will produce 300 or 400 eggs, or even more. The females are always larger than the males; they are also more slow in their motions; and some of them have no wings, or at the most only very small ones.

The care of all the butterfly tribe to lodge their eggs in safety is surprising. Those whose eggs are to be hatched in a few weeks, and who are to live in the caterpillar state during part of the remaining summer, always lay them on the leaves of such plants as will afford a proper nourishment: but, on the contrary, those whose eggs are to remain unhatched till the following spring, always lay them on the branches of trees and shrubs, and usually are careful to select such places as are least exposed to the rigour of the ensuing season, and frequently cover them from it in an artful manner. Some make a general coat of a hairy matter over them; others hide themselves in hollow places in trees, and other cells, and there live in a kind of torpid state during the winter, that they may deposit their eggs in the succeeding spring.

It is well known that the common food of these creatures is the leaves and verdure of vegetables; yet, as harmless as they seem, they will many of them destroy their fellows whenever they get an opportunity. These species, however, though freed from such dangers, are exposed to others of a more terrible kind; the worms or maggots of several sorts of flies are frequently found about them, some preying upon their outside, others lodged within them under the skin, but both kinds eating the creature up alive.

Nothing is more surprising in insects than their industry: and in this the caterpillars yield to no kind, not to mention their silk, the spinning of which is one great proof of it. The cases which some of these insects build for passing their transformations under, are by some made with their own hair, mixed with pieces of bark, leaves, and other parts of trees, with paper, and other materials. There is one which builds in wood, and is able to give its case a hardness greater than that of the wood itself in its natural state. This is the horned caterpillar of the willow, which is one of these that eat their exuviæ. This creature has sharp teeth, and with these it cuts the wood into small fragments; these it unites together into a case, of what shape it pleases, by means of a viscous juice, which hardens as it dries, and is a strong and firm cement.

The butterfly, as soon as hatched, discharges a liquor which softens the viscous matter that holds the case together; and so its several fragments, falling to pieces, it escapes.

Another very curious artifice is, that by which some species of caterpillars, when the time of their changing into the chrysalis state is coming on, make themselves lodgments in the leaves of the trees, by rolling them up in such a manner as to form a sort of hollow cylindric case, proportioned to the thickness of their body, well defended. Besides those caterpillars, which roll up the leaves of plants, there are other species which only bend them once, and others, which by means of thin threads, connect many leaves together to make them a case.

Caterpillars are very destructive to gardens, particularly those of two species. The one that which afterwards becomes the common white butterfly. This is of a yellowish-white colour, spotted with black, and infests the leaves of cabbages, cauliflowers, and the Indian

cress, of which it eats off all the tender parts, leaving only the fibres entire. There is no remedy against this evil but the pulling the creatures off before they are spread from their nests, and watching the butterflies, which are daily, in the hot weather, depositing their eggs on these plants.

Erucæ *aquaticæ, water-caterpillars.* M. Reaumur, in his observations, met with two species of these; the one upon the pond-weed, the other upon the lenticula or duck-meat. These are both very industrious animals; but the first being much the largest, its operations are more easily distinguished. This, though an aquatic animal, swims but badly, and dislikes the water. The parent butterfly lays her

This it carries to another part of the same leaf, and lays it in such a manner, that there may be a hollow between, in which it may lodge. It then fastens down this piece to the larger leaf with silk of its own spinning, only leaving holes

since a little force from its body bends up the upper leaf and down the lower, both being flexible; and when the creature is out, it has a sort of down that defends it from being wetted, and the natural elasticity of the leaves and silk joins the aperture again, so that no water can get in. The leaves of this kind of plant are also naturally slippery, and not easily wetted by water. The changes of this creature into the chrysalis and butterfly states are in the common method. The butterfly gets out of a chrysalis which was placed on the surface of the water; the lightness of the animal sustains it on the water till its wings are dried, and then it leaves that element, never to return to it again.

Erucæ *sylvestres,* wood caterpillars, do not live on leaves of trees or plants, but under the bark, in the trunk and branches, and in the roots of trees, and sometimes in the body of fruits.

Of these species, some go out of their prison to change into their chrysalis, and thence into their butterfly state; but the greater number remain there, and pass through all their changes within. These caterpillars, like all the other kinds, have certain flesh-eating worms, whose parents are of the fly-kind, for their destroyers; and it is not unfrequent, on opening one of these spoiled fruits, instead of the caterpillar, to find a fly just ready to come out: this has been produced from the chrysalis of a worm, which had found its way into the fruit, and eaten up the original possessor of the place.

ERUCTATIONS, in medicine, are the effect of flatulent foods, and the crudities thence arising.

ERUPTION, in medicine, a sudden and copious excretion of humours, as pus or blood; it signifies also the same with exanthema, any breaking out; as the pustules of the plague, small-pox, measles, &c.

ERVUM, the lentil, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32nd order, papilionaceæ. There are six species; of which the most remarkable is the lens, or common lentil. It is cultivated in many parts of England, either as fodder for cattle, or for the seeds, which are frequently used in meagre soups. It is an annual plant, and rises with weak stalks about 18 inches high, with winged leaves composed of several pairs of narrow lobes, terminated by a clasper or tendril, which fastens to any neighbouring plant, and is thereby supported; the flowers come out three or four together, upon short footstalks from the side of the branches. They are small, of a pale purple colour, and are succeeded by short flat pods, containing two or three seeds which are flat, round, and a little convex in the middle.

There is another sort of lentil also cultivated

cultivation than the other.

ERYNGIUM, sea-holly, or eryngo, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The flowers are

ducing erect stalks from one to two or three feet high: with simple, entire, or divided prickly leaves; and the stalks terminated by roundish, aggregate heads of quinquepetalous flowers of white, blue, or purple colours. They all flower mostly in July, and the seeds ripen in September.

ERYSIMUM, hedge-mustard; a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. The *siliqua* is long, linear, and exactly tetragonal; the calyx close. There are eight species; of which the most remarkable is the officinale, hedge-mustard, or bank cresses. It grows naturally in Britain under walls by the sides of highways, and among rubbish.

ERYSIPELAS, in medicine, an eruption of a fiery or acrid humour, from which no part of the body is exempted, though it chiefly attacks the face.

ERYTHRINA, coral-tree; a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32nd order, papilionaceæ. There are seven species, all of them shrubby flowering exotics for the stove, adorned chiefly with trifoliate or three-lobed leaves, and scarlet spikes of papilionaceous flowers. They are all natives of the warm parts of Africa and America.

ERYTHRONIUM, dog's tooth violet, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. There is only one species; which, however, admits of several varieties in its flowers, as white, purple, pale red, dark red, crimson, and yellow. The plants are low and herbaceous, with a purple stalk and hexapetalous flowers.

ERYTHROXYLON, a genus of the trigynia order, in the decandria class of plants; and in the natural method ranking in the doubtful order. There are five species, beautiful shrubs of the West Indies.

ESCALADE, in war, a furious attack of a wall or a rampart; carried on with ladders, to

pass the ditch or mount the rampart, without proceeding in form, breaking ground, or carrying on regular works to secure the men. Since the invention and use of gunpowder, and the walls of cities have been flanked, they are seldom taken by escalade.

ESCALLONIA, a genus of the monogynia order, in the pentandria class of plants. The fruit is bilocular and polyspermous; the petals distant and tongue-shaped; and stigma headed. There are two species, shrubs of the West Indies and South America.

ESCAPE, in law, is where one, who is arrested, gains his liberty before he is delivered by course of law.

Escapes are either in civil or criminal cases; and in both respects may be distinguished into voluntary, and negligent; voluntary, where it is with the consent of the keeper; negligent, where it is for want of due care in him. In civil cases, after the prisoner has been suffered voluntarily to escape, the sheriff can never retake him, but must answer for the debt; but the plaintiff may retake him at any time. In the case of a negligent escape, the sheriff, upon fresh pursuit, may retake the prisoner; and the sheriff shall be excused, if he has him again before any action brought against himself for the escape.

ESCAPEMENT. See SCAPEMENT.

ESCHALOT. See ALLIUM.

ESCHEAT, in our law, denotes an obstruction of the course of descent, and a consequent determination of the tenure, by some unforeseen contingency; in which case, the land naturally results back, by a kind of reversion, to the original grantor or lord of the fee.

ESCLATTE, in heraldry, signifies a thing forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCUTCHEON, in heraldry, is derived from the French *escusson*, and that from the Latin *scutum*, and signifies the shield whereon coats of arms are represented.

ESCUTCHEON *of pretence*, that on which a man carries his wife's coat of arms; being an heiress, and having issue by her. It is placed over the coat of the husband, who thereby shows his pretensions to her lands.

ESOX, *pike*, a genus of fishes of the order abdominales. The generic character is, head somewhat flattened above, mouth wide; teeth sharp, in the jaws, palate, and tongue; body lengthened; dorsal and anal fin (in most species) placed near the tail, and opposite each other. There are nine species, of which the most remarkable are:

1. *Esox lucius*, or common pike. It is, says Pennant, a native of most of the lakes and smaller rivers in Europe, but the largest are those of Lapland, which are sometimes eight feet in length: they are taken there in great abundance, dried, and exported for sale. The largest specimen of English growth is said to have weighed thirty five pounds. The head of the pike is very flat; the upper jaw broad, and shorter than the lower, which turns up a little at the end, and is marked with minute punctures: the teeth are very sharp, disposed only in front of the upper jaw, but in both sides of the lower, as well as in the roof of the mouth, and often on the tongue: the number, is not less than seven hundred, without reckoning those nearest the throat: it is also to be observed that those which are situated on the jaws are alternately fixed and moveable; the gape is very wide, and the eyes small. The usual colour of this fish is a pale olive-grey, deepest on the back, and marked on the sides by several yellowish spots or patches: the abdomen is white, slightly spotted with black.

The voracity of the pike is commemorated by all ichthyological authors. Mr. Pennant observes that he has known a pike that was choaked in attempting to swallow one of its own species. It will also devour water-rats, and young ducks which happen to be swimming near it.

The longevity of the pike is very remarkable, if we may credit the accounts given by authors. Rzaczynski in his Natural History of Poland tells us of one that was ninety years old; but Gesner relates that in the year 1497, a pike was taken near Hailburn, in Suabia, with a brass ring affixed to it, on which were these words in Greek characters: "I am the fish which was first of all put into this lake by the hands of the governor of the universe, Frederic the Second, the fifth of October 1230."

The pike spawns in March and April according to the warmth or coldness of the season; depositing its ova among the weeds, &c. near the water's edge: the young are said to be of very quick growth.

2. *Esox sphyræna*, or sea-pike. This species is of a silvery blueish colour, dusky on the back, and slightly tinged with yellow on the head and about the gills: the first dorsal fin is situated on the middle of the back, and is furnished with only four rays; the second, which is placed opposite the anal fin, consists of about ten rays; both these dorsal fins, together with the tail, which is deeply forked, are of a dusky tinge; the pectoral, ventral, and anal, are of a pale red, the eyes are moderately large. This fish is an inhabitant of the Mediterranean and Atlantic seas, growing to the length of about two feet.

3. *Esox barracuda*, or barracuoa pike, has the habit of the common pike; the size is very great, some having been seen of ten feet in length; but the more common size is from six to eight feet. This is said to be an extremely strong, fierce, and dangerous fish, swimming with great rapidity, and preying on most others; it is even said sometimes to attack and destroy bathers, in the same manner as the shark. It is found in great plenty in the tropical seas, and about the West Indian islands.

4. *Esox vulpes*, or the fox pike. Its general length is about sixteen inches: habit somewhat similar to that of a common pike, but remarkably slender or taper towards the tail, which is very deeply and widely forked; mouth of moderate width: jaws equal, and with a single row of sharp teeth in each: dorsal fin situated in the middle of the back; scales rather large, thin, and roundish: colour of the whole fish brown, native of Carolina and the West Indian islands.

5. *Esox Malabaricus*, or Malabar pike, is in length about twelve inches; habit distantly allied to that of the common pike, but with the tail rounded, and the dorsal fin placed on the middle of the back, colour yellowish, dusky on the back; lower jaw longer than the

upper; eyes rather large; scales large, and very distinct.

6. *Esox bellona*, gar fish, or sea-needle, is well known by its protracted snout, and the bones, which are green when boiled.

ESPALIERS, in gardening, are rows of trees trained up regularly to a lattice of wood-work in a close hedge, for the defence of tender plants against the injuries of wind and weather.

ESPLANADE, in fortification, the sloping of the parapet of the covered way towards the campaign. It is the same with glacis, and is more properly the empty space betwixt a citadel and the houses of a town, commonly called a place of arms.

ESQUIRE was anciently the person that attended a knight in the time of war, and carried his shield. This title has not, for a long time, had any relation to the office of the person, as to carry arms, &c. Those to whom the title of esquire is now of right due, are all noblemen's younger sons, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons; the officers of the king's courts, and of his household: counsellors at law, justices of the peace, &c. though those latter are only esquires in reputation: besides, a justice of the peace holds this title no longer than he is in commission in case he is not otherwise qualified to bear it; but a sheriff of a county, who is a superior officer, retains the title of esquire during life, in consequence of the trust once reposed in him; the heads of some ancient families are said to be esquires by prescription.

ESSENCE, in chemistry, denotes the purest, most subtile, and balsamic parts of a body; extracted either by simple expression, or by means of fire, from fruits, flowers, and the like. Of these there is a great variety, used on account of their agreeable smell and taste, by apothecaries, perfumers, and others.

ESSOIN, in law, an excuse for a person summoned to appear and answer to an action on account of sickness or other just cause of his absence.

ESSOIN-*day*, is regularly the first day of every term, though the fourth day after is also allowed by way of indulgence.

ESTATE, in law, signifies such inheritance, freehold, term for years, tenantcy by statute-merchant, staple, elegit, or the like, as any man has in lands and tenements. Estates are real, of lands, tenements, &c. or personal, of goods or chattels: otherwise distinguished into freeholds that descend to the heir, and chattels which go to the executors.

ESTOILEE', or *cross estoilee*, in heraldry, a star with only four long rays in form of a cross; and, accordingly, broad in the centre, and terminating in sharp points.

ESTOPPEL, in law, an impediment or bar to an action, which arises from a person's own act; or rather, where he is forbidden by law to speak against his deed, which he may not do, even to plead the truth.

ESTOVERS, in law, is a liberty of taking necessary wood for the use or furniture of a house or farm. And this any tenant may take from off the land let or demised to him.

ESTRAYS and WAIFS. Estrays are any valuable beasts, not wild, found within a lordship whose owner is not known; such as are commonly impounded and not claimed. They are then to be proclaimed in the church and the two nearest market-towns, on two market-days, and not being claimed by the owner, belong to the king, and now commonly by grant of the crown, to the lord of the manor, or the liberty. Beasts *ſeræ naturæ*, cannot be estrays.

ESTREAT, is a true copy or note of some original writing on record, and especially of fines and amercements imposed in the rolls of a court, and extracted or drawn out thence, and certified into the Court of Exchequer.

ETCHING, is a manner of engraving on copper, in which the lines or strokes, instead of being cut with a tool or graver, are corroded in with aqua-fortis.

In almost all the engravings on copper that are executed in the stroke manner, etching and graving are combined, the plate being generally begun by etching, and finished with the graver. Landscapes, architecture, and machinery, are the subjects that receive most assistance from the art of etching; for it is not so applicable to portraits and historical designs. See ENGRAVING.

ETHER, a very volatile fluid produced by the distillation of alcohol with an acid. Ether is of various kinds, according to the acid used in its production; but that which has been longest known, and is most in demand is the sulphuric ether.

The method of procuring this substance is as follows. Put into a retort a convenient quantity of alcohol, and add an equal weight of strong sulphuric acid; the whole must be mingled as intimately as possible by a gentle agitation.

The retort must now be placed in a sand bath, and connected with a large receiver, kept cool by being surrounded with ice, if it can be obtained, or placed in water. The first product is a fragrant spirit of wine; and as soon as the fluid in the retort begins to boil, the ether comes over. At this period of the process the upper part of the receiver is covered with large distinct streams of the fluid which run down its sides. There should be a bent glass tube luted to the tubulure of the receiver, and having its extremity immersed in water or mercury, to allow the gases to escape, and the more effectually to confine the condensible vapour.

After the ether a light yellow oil, called oil of wine, comes over: and this is followed by black and foul sulphuric acid. Great care is necessary, on the part of the operator, in extracting ether, as from its extreme inflammability, the danger of explosion attending the sudden mixture and agitation of alcohol with concentrated acids; and the suffocating effect of the elastic fluids, which, if disengaged, might fill the apartment, serious accidents sometimes happen. Sulphuric ether acts upon most of the resinous substances; it dissolves the essential oils and camphor; and burns with a more luminous flame than alcohol, producing more smoke. It boils at the temperature of 98° Fahr.; and in evaporating produces extreme cold. In medicine it is extensively useful.

ETHICS, or *morality*, the science of manners or duty, which it traces from man's nature and condition, and shews to terminate in his happiness; or, in other words, it is the knowledge of our duty and felicity, or the art of being virtuous and happy.

ETHMODIAL, in anatomy, one of the common sutures of the skull, which goes round the os ethmoides, from which it derives its name, separating it from the bone in contact with it.

ETHULIA, a genus of the class and order syngenesia polygamia æqualis. The receptacle is naked; down none. There are six species, chiefly annuals of the East Indies.

ETHUSA, fool's parsley. See ÆTHUSA.

ETNA. See VOLCANO.

ETYMOLOGY, that part of grammar which considers and explains the origin and derivation of words, in order to arrive at their first and primary signification, whence Quintilian calls it *originatio*. See GRAMMAR.

EVAPORATION. A chemical operation usually performed by applying heat to any compound substance, in order to dispel the volatile parts. It differs from distillation in its object, which chiefly consists in preserving the more fixed matters, while the volatile substances are dissipated and lost. And the vessels are accordingly different; evaporation being commonly made in open shallow vessels, and distillation in an apparatus nearly closed from the external air.

The degree of heat must be duly regulated in evaporation. When the fixed and more volatile matters do not greatly differ in their tendency to fly off, the heat must be very carefully adjusted; but in other cases this is less necessary.

As evaporation consists in the assumption of the elastic form, its rapidity will be in proportion to the degree of heat, and the diminution of the pressure of the atmosphere. A current of air is likewise of service in this process.

EUCALYPTUS, a genus of the hexandria monogynia class and order. There are two species; lofty trees of New Holland; called also the red-gum tree, from a gummy matter, in which one of them, the resinifera, abounds. A single tree will, on being tapped, afford more than 60 gallons of juice.

EUCLEA, a genus of the diœcia dodecandria class and order. There is one species, a branching tree of the Cape.

EUCOMIS, a genus of the class and order hexandria monogynia. There are four species, plants of the Cape.

EUDIOMETER. An instrument for ascertaining the purity of air, or rather the quantity of oxygen contained in any given bulk of elastic fluid. Dr Priestly seems to be the original inventor of this instrument; but it has been much improved since his day by the ingenuity of Dr. Hope of Edinburgh, and Dr. Ure of Glasgow. The contrivance of Dr. Ure seems entitled to general preference from its combining the desirable properties of simplicity, convenience, cheapness, safety. and precision.

EVERGREEN, in gardening, a species of perennials which continue their verdure, leaves, &c. all the year; such are hollies, phillyria's, laurustinus's, bays, pines, firs, cedars of Lebanon, &c.

EVERLASTING *pea*, the name of a perennial plant of the vetch kind, which grows naturally in some places, is easily cultivated, annually yields plenty of excellent provender, and may be cultivated to advantage as green food for cattle, on almost any strong soil.

EVES *droppers*, or EAVES *droppers*, persons who listen under walls or windows, or the eaves of a house, by night or day, to hear news, and to carry them to others to cause strife among neighbours; and who may be presented at the leet, or bound to their good behaviour, and punished by stat. Westminster, 1. c. 33.

EVIDENCE, is the testimony adduced before a court or magistrate of competent jurisdiction.

This may be of two kinds, viz. written or verbal: the former by deeds, bonds, or other written documents; the latter by witnesses examined *viva voce*.

Evidence may be further divided into absolute and presumptive; the former is direct, in positive or absolute affirmance or denial of any particular fact; the latter collateral, and from the conduct of the parties, affords an inference that such a particular fact did or did not occur.

EVOLUTION. See ALGEBRA.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preserve a post, or occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better.

EVOLVULUS, a genus of the tetragynia order, in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. There are seven species, herbaceous plants, chiefly annuals of the East and West Indies.

EUPATORIUM, hemp-agrimony; a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. There are 49 species, many of them herbaceous flowery perennials, producing annual stalks from two to three or five feet high, terminated by clusters of compound flowers of a red, purple, or white colour. One species, viz. the cannabinum, or water hemp-agrimony, is a native of Britain. It is found wild by the sides of rivers and ditches, and has pale red blossoms.

EUPHONY, in grammar, an easiness, smoothness, and elegance in pronunciation. It is properly a figure, whereby we suppress a letter that is too harsh, and convert it into a smoother, contrary to the ordinary rules; of this there are abundance of examples in all languages.

EUPHORBIA, spurge, a genus of the trigynia order, in the dodecandria class of plants; and in the natural method ranking under the 38th order, tricoccæ. There are 98 species, six of which are natives of Great Britain. They are mostly shrubby and herbaceous succulents, frequently armed with thorns, having stalks from ten to twelve inches to as many feet in height, with quadri-petalous flowers of a whitish or yellow colour. There is a species at the Cape, which supplies the Hottentots with an ingredient for poisoning their arrows.

EUPHRASIA, eyebright (from a vulgar notion that it was good in disorders of the eyes;) a genus of the angiospermia order, in the didynamia class of plants; and in the na-

tural method ranking under the 40th order, personatæ. There are nine species; two of which annuals, viz. the officinalis and adonties, are natives of Britain. The first of these, which has blue flowers, is a weak astringent, and was formerly much celebrated in disorders of the eyes; but the present practice has disregarded its use.

EURYTHMY, in architecture, painting, and sculpture, is a certain majesty, elegance, and easiness, appearing in the composition of divers members, or parts of a body, painting, or sculpture, and resulting from the fine proportion of it. Vitruvius ranks the eurythmia among the essential parts of architecture; he describes it as consisting in the beauty of the construction, or assemblage of the several parts of the work, which renders its whole appearance beautiful.

EXACUM, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. There are 10 species, allied to the gentians, chiefly annuals, of the East Indies and Cape.

EXAGGERATION, in rhetoric, a kind of hyperbole, whereby things are augmented or amplified, by saying more than the truth, either as to good or bad. There are two kinds of exaggeration; the one of things, the other of words.

EXCELLENCY, a title anciently given to kings and emperors, but now to ambassadors and other persons, who are not qualified for that of "highness," and yet are to be elevated above the other inferior dignities.

EXCENTRIC, in geometry, a term applied to circles and spheres which have not the same centre, and consequently are not parallel; in opposition to concentric, where they are parallel, having one common centre.

EXCENTRICITY, in astronomy, is the distance of the centre of the orbit of a planet from the centre of the sun, that is, the distance between the centre of the ellipsis and the focus.

EXCEPTION, in law, is a stop or stay to any action. In law proceedings, it is a denial of a matter alleged in bar to an action; and in Chancery, it is what is alleged against the sufficiency of an answer.

EXCHANGE, in law, is a mutual grant of equal interests, the one in consideration of the other.

In exchange, the estates of both parties should be equal; that is, if the one has a fee-simple in the one land, the other should have a like estate in the other land: and if the one has fee-tail in the one land, the other ought to have the like estate in the other land; and so of other estates.

Exchange, in arithmetic and commerce, is the reduction of different coins of any denominations of money from one to another: or it is the method of finding how many of one species or denomination are equal to a given number of another; in order to which it is necessary to know the value of the coins of different countries, and the proportion to each other according to the settled rate of exchange. The several operations in this case are only different applications of the rule of three. It is obvious that the true par of exchange must be subject to frequent fluctuation from the variations that take place in the comparative value of gold and silver; and also from the alterations frequently made in the value of the coins of different countries.

To remedy the inconveniencies arising from these and other causes that necessarily operate in extensive commerce, lists of the courses of exchange are issued from the principal trading places in Europe. These lists are called *Quotations*, and may always be obtained at the Royal Exchange. Lloyd's list exhibits the quotation at London.

As the subject of exchanges is generally introduced into respectable treatises on arithmetic, and thus rendered accessible to all at an easy rate, it is deemed unnecessary to occupy our pages with it: the necessary tables, together with suitable rules for the various operations, specimens of quotations, &c. are amply exhibited in Keith's Complete Practical Arithmetician. The reader will also find an able article on exchanges in Dr. Kelly's Elements of Book-keeping; but the most complete work of this nature in the English language, is the Universal Cambist, by the last-named author, which is founded on the celebrated German work of Kruse, intitled the Hamburgh Contorist.

EXCHEQUER, from the French *eschequier*. i. e. *abacus tabula lusoria*, is a court of law and equity, established by William the Conqueror, as a part of the *aula regis*; but reduced to its present state by Edward I. and intended principally to order the revenue of the crown, and to recover the king's debts and duties. The court consists of two divisions, viz. the receipt of the exchequer, which manages the royal revenues; and the judicial, which is again subdivided into a court of equity, and a court of common law. The court of equity is held in the Exchequer, before the Lord Treasurer, the Chancellor of the Exchequer, the Chief Baron, and three puisne Barons.

EXCISE *duties*, inland taxes on commodities of general consumption. This mode of taxation, having been always found very productive, has been adopted by all the European governments, and by some of them has been extended even to the necessaries of life; but, in general, the articles subjected to it have been such as are not absolutely essential to subsistence. Salt appears to have been the object of an excise duty at a very early period: in later times oil, wine, tobacco, and various other consumable articles have been burthened with duties of this description.

EXCLAMATION, in rhetoric, a figure that expresses the violent and sudden breaking out, and vehemence of any passion. Such is that in the second book of Milton's Paradise Lost.

> "O unexpected stroke! worse than of death,
> Must I thus leave thee, Paradise? Thus leave
> Thee, native soil; these happy walks and shades,
> Fit haunt of gods!"

Other figures are the language of some particular passion, but this expresses them all.

EXCOECARIA, a genus of the triandria order, in the dioecia class of plants; and in the natural method ranking under the 38th order, tricoccæ. There are two species. The agallocha, or aloes wood, is a native of China

and some of the Indian islands, and is about the same height and form as the olive-tree. Its trunk is of three colours, and contains three sorts of wood; the heart is that of tambac, or calombac, which is dearer in the Indies than even gold itself.

EXCOMMUNICATION, an ecclesiastical penalty or censure whereby such persons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

EXCORIATION, in medicine and surgery, the galling or rubbing off of the cuticle.

EXCRESCENCE, in surgery, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or tubercle.

EXCRETION, or SECRETION, in medicine, a separation of some fluid, mixed with the blood, by means of the glands.

EXCRETORY, in anatomy, a term applied to certain little ducts or vessels, destined for the reception of a fluid, secreted in certain glandules, and other viscera, for the excretion of it in the appropriated places.

EXECUTION is a judicial writ, grounded on the judgment of the court whence it issues; and is supposed to be granted by the court at the request of the party at whose suit it is issued, to give him satisfaction on the judgment which he has obtained: and therefore an execution cannot be sued out in one court, upon a judgment obtained in another.

Executions in actions where money is recovered, as a debt or damages, are of five sorts: 1. Against the body of the defendant; 2. against his goods or chattels; 3. against his goods and the profits of his lands; 4. against the goods and the possession of his lands; 5. against all three, his body, lands, and goods.

EXECUTION *of criminals*, must be according to the judgment; and the king cannot alter a judgment from hanging to beheading, because no execution can be warranted, unless it is pursuant to the judgment.

Execution of criminals is the completion of human punishment; and this in all cases, as well capital as otherwise, must be performed by the legal officer, the sheriff or his deputy.

EXECUTOR, is a person appointed by the testator, to carry it to execution his will and testament after his decease. The regular mode of appointing an executor, is by naming him expressly in the will; but any words indicating an intention of the testator to appoint an executor will be deemed a sufficent appointment.

EXEGESIS, In the Scotch universities there is an exercise among the students in divinity called an exegesis, in which a question is stated by the respondent, who is then opposed by two or three other students in their turns; during which time the professor moderates, and solves the difficulties which the respondent cannot overcome.

EXEMPLIFICATION *of letters patent*, a transcript or a duplicate of them, made from the enrolment thereof, and sealed with the great seal.

EXERCISE, among physicians, such an agitation of the body as produces salutary effects in the animal economy. Exercise may be said to be either active or passive. The active is walking, hunting, dancing, playing at bowls and the like; as also speaking, and other labour of the body and mind; the passive is riding in a coach, on horseback, or in any other manner.

EXERCISE, in military affairs, is the practice of all those motions and actions, together with the whole management of arms, which a soldier is to be perfect in, to render him fit for service, and make him understand how to attack and defend.

EXHALATION, a general term for all the effluvia or steams raised from the surface of the earth in form of vapour. Some distinguish exhalations from vapours, expressing by the former all steams emitted from solid bodies, and by the latter the steams raised from water and other fluids.

EXHAUSTIONS, or *the method of exhaustions*, a method of demonstration founded upon a kind of exhausting a quantity, by continually taking away certain parts of it.

The method of exhaustions was of frequent use among the ancient mathematicians, as Euclid, Archimedes, &c. It is founded on what Euclid says in the 10th book of his Elements, viz. that those quantities are equal whose difference is less than any assignable quantity.

EXIGENT, in law, signifies a writ or part of the process of outlawry on civil actions.

EXISTENCE, has been defined:—a state of being; actual possession of being. Mr. Locke says:—"We arrive at the knowledge of our own existence by intuition; of the existence of God by demonstration; and of other things by sensation. As for our own existence," continues that great philosopher, "we perceive it so plainly, that it neither needs, nor is capable of any proof. I think, I reason, I feel pleasure and pain; can any of these be more evident to me than my own existence? If I doubt of all other things, that very doubt makes me perceive my own existence, and will not suffer me to doubt it. If I know I doubt, I have as certain a perception of the thing doubting, as of that thought which I call doubt: experience then convinces us that we have an intuitive knowledge of our own existence."

From the knowledge of our own existence, Mr. Locke deduces his demonstration of the existence of a God.

EXOCOETUS, or the *flying-fish*, in ichthyology, a genus belonging to the order of abdominales. The head is scaly, and it has no teeth; it has 10 radii in the branchiostege membrane; the body is whitish, and the belly is angular; the pectoral fins are very large. When pursued by any other fish, it raises itself from the water by means of these long fins, and flies in the air to a considerable distance, till the fins dry, and then it falls down into the water. It is a fish that seems to lead a most miserable life. In its own element it is perpetually harassed by the dorados and other fish of prey. If it endeavours to avoid them by having recourse to the air, it either meets its fate from the gulls or the albatross, or is forced down again into the mouths of the inhabitants of the water, who below keep pace with its aerial excursions. This fish is caught in the Mediterranean and some other seas, but is most common between the tropics.

EXORDIUM, in rhetoric, is the preamble

or beginning, serving to prepare the audience for the rest of the discourse.

EXOTIC, an appellation denoting a thing to be the produce of foreign countries. Exotic plants of the hot climates are very numerous, and require the utmost attention of the gardener to make them thrive with us.

EXPANSION, denotes an increase of the bulk of any body by a power acting from within.

It may be laid down as a general rule, to which there is no known exception, that every addition or abstraction of caloric makes a corresponding change in the bulk of the body which has been subjected to this alteration in the quantity of its heat. In general, the addition of heat increases the bulk of a body, and the abstraction of it diminishes its bulk; but this is not uniformly the case, though the exceptions are not numerous.

Though all bodies are expanded by heat and contracted by cold, and this expansion in the same body is always proportional to some function of the quantity of caloric added or abstracted, yet the absolute expansion, or contraction, has been found to differ exceedingly in different bodies. In general, the expansion of gaseous bodies is greatest of all; that of liquids is much smaller, and that of solids the smallest of all. Thus, 100 cubic inches of atmospheric air, by being heated from the temperature of 32° to that of 212°, are increased to 137.5 cubic inches; while the same augmentation of temperature only makes 100 cubic inches of water assume the bulk of 101.5 cubic inches; and 100 cubic inches of iron, when heated from 32° to 212°, assume a bulk scarcely exceeding 100.1 cubic inches. From this example, we see that the expansion of air is more than eight times greater than that of water, and the expansion of water about 45 times greater than that of iron.

EX PARTE, a term used in the Court of Chancery, when a commission is taken out and executed by one side or part only, upon the other party's neglecting or refusing to join therein. When both the parties proceed together, it is called a joint commission.

EXPECTATION, in the doctrine of chances, is applied to any contingent event, upon the happening of which some benefit, &c. is expected. This is capable of being reduced to the rules of computation; for a sum of money in expectation when a particular event happens, has a determinate value before that event happens. Thus, if a person is to receive any sum as 10*l.* when an event takes place which has an equal chance or probability of happening or failing, the value of the expectation is half that sum, or 5*l.*; but if there are three chances for failing, and only one for its happening, or one chance only in its favour out of all the four chances, then the probability of its happening is only one out of four, or $\frac{1}{4}$, and the value of the expectation is but $\frac{1}{4}$ of 10*l.* which is only 2*l.* 10*s.* or half the former sum. And in all cases, the value of the expectation of any sum is found by multiplying that sum by the fraction expressing the probability of obtaining it. So the value of the expectation on 100*l.* when there are three chances out of five for obtaining it, or when the probability of obtaining it is three fifth part of 100*l.* which is 60*l.* And if s be any sum expected on the happening of an event, h the chances for that event happening, and f the chances for it failing; then, there being h chances out of $f+h$ for its happening, the probability will be $\frac{h}{f+h}$, and the value of the expectation is $\frac{h}{f+h} \times s$.

EXPECTORANTS, an appellation given to those medicines which facilitate the discharging the cont[illegible] of the lungs.

EXPECTORATION, the act of evacuating or bringing up phlegm, or other matters out of the trachea, lungs, &c. by coughing, hanking, spitting, &c.

EXPERIMENTAL *philosophy*, that philosophy which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations.

In our enquiries into nature, we are to be conducted by those rules and maxims which are found to be genuine, and consonant to a just method of physical reasoning; and these rules of philosophizing are by the greatest master in science, Sir Isaac Newton, reckoned four, which are as follows:

1. More causes of natural things are not to be admitted, than are both true, and sufficient to explain the phænomena; for nature does nothing in vain, but is simple, and delights not in superfluous causes of things.

2. And, therefore, of natural effects of the same kind, the same causes are to be assigned, as far as it can be done; as of respiration in man and beasts, of the descent of stones in Europe and America, of light in a culinary fire and in the sun, and of the reflection of light in the earth and in the planets.

3. The qualities of natural bodies which cannot be increased or diminished, and agree to all bodies on which experiments can be made, are to be reckoned as the qualities of all bodies whatever; thus, because extension, divisibility, hardness, impenetrability, mobility, the vis inertiæ, and gravity, are found in all bodies which fall under our inspection, we may justly conclude they belong to all bodies whatever, and are therefore to be esteemed the original and universal properties of all natural bodies.

4. In experimental philosophy, propositions collected from the phænomena by induction, are to be deemed (notwithstanding contrary hypotheses) either exactly or very nearly true, till other phænomena occur, by which they may be rendered either more accurate, or liable to exception. This ought to be done, lest arguments of induction should be destroyed by hypotheses.

EXPERIMENTUM CRUCIS, a leading, or decisive experiment; thus termed, either on account of its being like a cross, or direction post, placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are enquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is in a manner extorted by force.

EXPLOSION, in natural philosophy, a sudden and violent expansion of an aerial, or other elastic fluid, by which it instantly throws off any obstacle that happens to be in the way, sometimes with incredible force, and in such a

manner as to produce the most astonishing effects. It differs from expansion in this, that the latter is a gradual and continued power, acting uniformly for some time, whereas, the former is always sudden, and only of momentary duration. The expansions of solid bodies do not terminate in violent explosions, on account of their slowness, and the small space through which the metal, or other expanding substance, moves. Thus wedges of dry wood driven into stone, and wetted, will cleave the most solid blocks; but they never throw the parts to any distance, as is the case with gunpowder; but the expansion of elastic fluids will burst solid substances, and throw the fragments a great way off: for this, two reasons have been assigned: 1. The immense velocity with which aerial fluids expand, when suddenly affected with high degrees of heat: and 2. The great celerity with which they acquire heat, and are affected by it. As an example: air when heated as much as iron, when brought to a white heat, is expanded to four times its bulk, but the metal itself will not be expanded the 500dth part of the space. In the case of gunpowder, which is well known as an explosive substance, the velocity with which the flame moves is estimated at 7000 feet in a second. Hence the impulse of the fluid is inconceivably great, and the obstacles on which it strikes are hurried off with vast velocity, *viz.* at the rate of 27 miles per minute. The velocity of the bullet is also promoted by the sudden propagation of the heat through the whole body of air, as soon as it is extricated from the materials of which the gunpowder is made, so that it strikes at once. Hence it has been inferred, that explosion depends first on the quantity of elastic fluid to be expanded: secondly, on the velocity it acquires by a certain degree of heat; and thirdly, on the celerity with which the degree of heat affects the whole expansile fluid.

EXPONENT, in *algebra*, is the same with index. See ALGEBRA.

EXPORTATION, in commerce, is the act of sending goods out of one country into another, by shipping, or otherwise.

EXPRESSED *oils*, in chemistry, such oils as are obtained from bodies only by pressing. See OIL.

EXPRESSION, in chemistry, or pharmacy, denotes the act of pressing out the juices or oils of vegetables, which is one of the three ways of obtaining them; the other two being by infusion and decoction.

EXPRESSION, in painting, is the distinct exhibition of character in the general object of the work, or of sentiment in the characters or persons represented.

In the latter case it consists either in representing the body in general and all its parts severally, in actions most peculiarly suitable to the design of the picture, and marking thereby the emotions of the soul in the various figures, or in pourtraying in the face the appearances of the passions.

EXTENSION, in philosophy, one of the common and essential properties of body, or that by which it possesses or takes up some part of universal space, which is called the place of that body.

EXTENSOR, an appellation given to several muscles, from their extending or stretching the parts to which they belong.

EXTENT, in law, a writ of execution or commission to the sheriff, of one who being bound by statute, has forfeited his bond, for the valuing of lands or tenements; sometimes the act of the sheriff upon this writ.

EXTERMINATION, in general, the extirpating or destroying something. In algebra, surds, fractions, and unknown quantities, are exterminated by the rules for reducing equations.

EXTRACT. When decoction is carried to such a point as to afford a substance either solid or of the consistence of paste, this residual product is called an extract. When chemists speak of extract, they most commonly mean the product of aqueous decoction; but the earlier chemists frequently speak of spirituous extract.

Extracts thus prepared are mixtures of several of the materials of vegetables, whence they differ greatly, according to the plants from which they are obtained; but modern chemists distinguish by the name of extract, or *extractive matter*, a peculiar substance, supposed to be one of the immediate materials of vegetables, and the same in all, when separated from any foreign admixture, except as the proportion of its constituent principles may vary.

EXTRACTION, in surgery, is the drawing any foreign matter out of the body by the hand, or by the help of instruments.

EXTRACTOR, in midwifery, an instrument, or forceps, for extracting children by the head.

EXTRAVASATION, in contusions, fissures, depressions, fractures, and other accidents of the cranium, is when one or more of the blood-vessels that are distributed on the dura mater, are broken or divided, whereby there is such a discharge of blood as greatly oppresses the brain, and disturbs its offices; frequently bringing on violent pains and other mischiefs, and at length death itself, unless the patient is relieved.

EXTREMES, in logic, the terms expressing the two ideas whose relation we enquire after in a syllogism.

EXUVIÆ, among naturalists, denote the cast-off parts or coverings of animals, as the skins of serpents, caterpillars, and other insects. See ERUCA.

EYE, in anatomy, the organ of sight, or that part of the body whereby visible objects are represented to the mind.

The term eye is used in a great variety of senses. In architecture, it signifies an aperture at the top of a dome, also the centre of a volute: in agriculture, it means either a little bud or shoot, ingrafted into a tree, or the part of a potatoe cut off for seed and in printing it is used for the graving in relievo on the top of the letter. In a symbolical sense, there is no term of which so much use is made to denote the operations of the understanding and the affections.

F.

F, The sixth letter of the alphabet, and the fourth consonant. It has much the same sound as the Greek φ, or *ph* in English words, and is only written in words of Latin origin, *ph* being used instead of it in words derived from the Greek.

As a numeral, F denotes 40, and with a dash over it thus $\bar{F}$, 40,000: in music, it stands for the bass clef; and frequently for *forte*, as *ff* does for *forte forte*.

As an abbreviation, F stands for *filius*, *fellow*, and the like: thus F. R. S. signifies Fellow of the Royal Society.

FA, in music, one of the syllables invented by Guido Aretine, to mark the fourth note of the modern scale, which rises thus, *ut*, *re*, *mi*, *fa*.

Musicians distinguish two *fa's*, *viz.* the flat, marked with a ♭, or ♭; and the sharp or natural, marked thus ♮, and called biquadro.

FABLE is used for the plot of an epic or dramatic poem, and is, according to Aristotle, the principal part, and, as it were, the soul of a poem.

FACE, comprehends all that part of the head which is not covered with the common long hair. See ANATOMY.

Face, or *facade*, in architecture, the front of a building, or the side which contains the chief entrance.

Face, in fortification, an appellation given to several parts of a fortress, as the face of a bastion, &c.

FACET, or *facette*, among jewellers, the name of the little faces or planes to be found in brilliant and rose diamonds.

FACTITIOUS, any thing made by art, in opposition to what is the produce of nature. Thus, factitious cinnabar is opposed to native cinnabar.

FACTOR, in commerce, is an agent or correspondent residing beyond the seas, or in some remote part, commissioned by merchants to buy or sell goods on their account, or assist them in carrying on their trade.

FACTORAGE, called also commission, is the allowance given to factors by the merchant who employs them.

FACTORY is a place where a considerable number of factors reside, to negotiate for their masters or employers. The most considerable factories belonging to the British are those established in the East Indies, Portugal, Turkey, &c.

FACULÆ, in astronomy, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed upon or about the surface of the sun: they are but very seldom seen.

Hevelius assures us that, on July 20, 1634, he observed a facula, the breadth of which was equal to a third part of the sun's diameter. He says too that the maculæ often change into faculæ, but these seldom or never into maculæ. And some authors even contend that all the maculæ degenerate into faculæ before they quite disappear. Many authors, after Kircher and Scheiner, have represented the sun's body full of bright, fiery spots, which they conceive to be a sort of volcanoes in the body of the sun; but Huygens, and others of the latest and best observers, finding that the best telescopes discover nothing of the matter, agree entirely to explode the phænomena of faculæ. All the foundation he could see for the notion of faculæ, he says, was, that in the darkish clouds which frequently surround the maculæ, there are sometimes seen little points or sparks brighter than the rest.

FACULTY, in law, a privilege granted to a person, by favour and indulgence, of doing what, by law, he ought not to do. For granting these privileges there is a court under the archbishop of Canterbury, called the court of the faculties.

Faculty, in the schools, a term applied to the different members of a university, divided according to the arts and sciences taught there: thus, in most universities there are four faculties: viz. 1. Of arts, which include humanity and philosophy. 2. Of theology. 3. Of physic. And 4. Of civil law. The degrees in the several faculties in our universites are those of bachelor, master, and doctor.

Faculty *of advocates*, a term applied to the college or society of advocates in Scotland, who plead in all actions before the court of session. They meet in the beginning of every year, and choose the annual officers of the society, viz. dean, treasurer, clerks, private and public examinators, and a curator of their library.

Faculty is also used to denote the powers of the human mind, viz. understanding, will, memory, and imagination.

FÆCES, in chemistry, the gross matter, or sediment, that settles at the bottom after distillation, fermentation, &c.

FÆCULA. See GLUTEN.

FAGARA, *iron wood*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 43 order, dumosæ. There are 10 species, all natives of the warm parts of America, rising with woody stems more than 20 feet high.

FAGG, in the sea language, a term given to the end of those strands which do not go through the tops, when a cable or rope is closed.

FAGONIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, gruinales. There are three species, herbaceous plants of Spain, Crete, and Arabia.

FAGRÆA, a genus of the class and order pentandria monogynia. There is one species, a shrub of Ceylon.

FAGUS, the *beech-tree*, a genus of the polyandria order, in the monœcia class of plants; and in the natural method raking under the 50th order, amentaceæ. There are five species. The most remarkable are,

1. The *sylvatica*, or beech-tree, rises 60 or 70 feet high, and has a proportionable thickness,

branching upward into a fine regular head, with oval serrated leaves, with flowers in globular catkins, succeeded by angular fruit called mast.

2. The *castanea*, or chesnut-tree, has a large upright trunk growing 40 or 50 feet high, branching regularly round into a fine spreading head, with large spear-shaped acutely serrated leaves, naked on the under side, having flowers in long amentums, succeeded by round prickly fruit, containing two or more nuts.

3. The *pumila*, dwarf chesnut-tree, or chinkapin, rises eight or ten feet high, with a braching shrubby stem, and oval-spear shaped and acutely serrated leaves, hoary on the under side. The wood of the beech tree, in point of usefulness, ranks next to the oak and the ash, and is much used by cabinet-makers and turners. The mast, or seeds yield a good oil for lamps; and are eaten by squirrels and swine.

FAILLIS, in heraldry, a French term denoting some failure or fraction in an ordinary, as if it were broken, or a splinter taken from it.

FAIR, a greater kind of market, granted to a town, by privilege, for the more speedy and commodious providing of such things as the place stands in need of.

FAIRY-*circle*, or *ring*, a phænomenon frequent in the fields, &c. supposed by the vulgar to be traced by the fairies in their dances: there are two kinds of it; one of about seven yards in diameter, containing a round bare path, a foot broad, with green grass in the middle of it. The other is of different bigness, encompassed with a circumference of grass, greener and fresher that that in the middle. Messrs. Jessop and Walker, in the Philosophical Transact. ascribed them to lightning: we have however examined them ourselves, and are convinced they are produced by a kind of fungus which breaks and pulverizes the soil; why this vegetable should put forth its offsets in this kind of circular direction we cannot rightly account. The circles however are seldom complete, and often very irregular.

FALCO, in ornithology, a genus belonging to the order of accipitres, the characters of which are these: the beak is crooked, and furnished with wax at the base; the head is thick-set with feathers, and the tongue is cloven. The eagle, kite, and hawk, form this genus. There are 32 species, of which the following are the most remarkable.

1. The *leucocephalus*, bald, or white-headed eagle of Catesby, is ash-coloured, with head and tail white; the iris of the eye is white, over which is a prominence covered with a yellow skin; the bill and the cere or wax are yellow, as are likewise the legs and feet; and the talons are black. Though it is an eagle of small size, it weighs nine pounds, is strong and full of spirit, preying on lambs, pigs, and fawns. They always make their nests near the sea or great rivers, and usually upon old dead pine or cypress trees, continuing to build annually on the same tree till it falls.

2. The *ossifragus*, *sea-eagle*, or osprey with yellow wax, and half feathered legs It is about the size of a peacock; the feathers are white at the base, iron coloured in the middle, and black at the points; and the legs are yellow. It is found in several parts of Great Britain and Ireland. All authors indeed agree, hat it feeds principally on fish, which it takes as they are swimming near the surface, by darting down upon them; not by diving or swimming, as some have pretended. Martin, speaking of what he calls the great eagles of the Western Isles, says, that they fasten their talons in the back of the fish, commonly of salmon, which are often above the water, or very near the surface. Those of Greenland will even take a young seal out of the water.

3. The *chrysaetos*, or golden eagle, weighs about twelve pounds, and is in length about three feet, the wings when extended measuring about seven feet four inches. The sight and sense of smelling are very acute: the head and neck are clothed with narrow sharp-pointed feathers, of a deep-brown colour bordered with tawny; the hind part of the head in particular is of a bright rust-colour. These birds are very destructive to fawns, lambs, kids, and all kinds of game, particularly in the breeding season, when they bring a vast quantity of prey to their young. Smith, in his History of Kerry, relates, that a poor man in that county got a comfortable subsistence for his family, during a summer of famine, out of an eagle's nest by robbing the eaglets of the food which the old one brought; whose attendance he protracted beyond the natural time, by clipping the wings and retarding the flight of the former.

Eagles are remarkable for their longevity, and for their power of sustaining a long abstinence from food. Mr. Keysler relates, that an eagle died at Vienna after a confinement of 104 years. This pre-eminent length of days probably gave occasion to the saying of the Psalmist, "Thy youth is renewed like the eagle's."

4. The *fulvus*, or white-tailed eagle of Edwards, has the whole plumage of a dusky-brown: the breast marked with triangular spots of white, but which are wanting in the British kind: the tail is white, tipped with black; but in young birds dusky, blotched with white: the legs are covered to the toes with soft rust-coloured feathers. These birds inhabit Hudson's-bay and northern Europe as far as Drontheim.

5. The *cyaneus*, or hen-harrier, with white wax, yellow legs, a whitish-blue body, and a white ring round the eyes and throat. It is the blue hawk of Edwards, and is a native of Europe and Africa. These birds are extremely destructive to young poultry and to the feathered game; they fly near the ground, skimming the surface in search of prey.

6. The *albicilla*, or cinereous eagle, is inferior in size to the golden eagle; the head and neck are of a pale ash-colour; the body and wings cinereous, clouded with brown; the quill feathers very dark; the tail white; the legs feathered but little below the knees, and of a very bright yellow. The male is of a darker colour than the female. This species is in size equal to the black eagle, and inhabits Europe as high as Iceland and Lapmark. It is common in Greenland, but does not extend to America; or, if it does, it varies into the white-headed eagle, to which it has great affinity.

7. The *maculatus*, or the crying eagle, with a dusky bill and yellow cere: the colour of the

plumage is a ferruginous brown; the coverts of the wings and scapulars are elegantly varied with white spots; the primaries dusky, the ends of the greater white; the breast and belly are of a deeper colour than the rest of the plumage, streaked downwards with dull yellow; the tail is dark brown, tipped with dirty white; the legs are feathered to the feet, which are yellow. The length of the bird is two feet. This species is frequent in Russia and Siberia; and extends even to Kamschatka. It is less generous and spirited than other eagles, and is perpetually making a plaintive noise. The Arabs used to train it for the chase; but its quarry was cranes and other birds, the more generous eagle being flown at antelopes and other quadrupeds.

8. The *milvus*, or kite, is a native of Europe, Asia, and Africa. This species generally breeds in large forests or woody mountainous countries. Its nest is composed of sticks, lined with several odd materials, such as rags, bits of flannel, rope, and paper. Its motion in the air distinguishes it from all other birds, being so smooth and even that it is scarcely perceptible. Sometimes it will remain quite motionless for a considerable space; at others glide through the sky without the least apparent action of its wings. They inhabit the north of Europe, as high as Jalsberg, in the very south of Norway; but do not extend farther. They quit Sweden in flocks at the approach of winter, and return in spring. Some of them winter about Astrakan; but the far greater part are supposed to retire into Egypt, being seen in September passing by Constantinople in their way from the north; and again in April returning to Europe, to shun the great heats of the East. They are observed in vast numbers about Cairo, where they are extremely tame, and feed even on dates, probably for want of other food.

9. The *gentilis*, or gentil falcon, inhabits the north of Scotland, and was in high esteem as a bold and spirited bird in the days of falconry. It makes its nest in rocks; it is larger than the gos-hawk; the head of a light rust-colour, with oblong black spots; the under side white, tinged with yellow; the back of a brown colour; the tail barred with black, and ash-colour; the tips of all the tail feathers white.

10. The *subbuteo*, or hobby, was used like the kestrel in the humbler kind of falconry; particularly in what was called daring of larks: the hawk was cast off; the larks, aware of their enemy, were fixed to the ground for fear; by which means they became a ready prey to the fowler, who drew a net over them. The back of the bird is brown: the nape of the neck white: and the belly pale, with brown spots. It is a bird of passage; but breeds in Britain, and migrates in October.

11. The *buteo*, or buzzard, is the most common of the hawk kind in England. It breeds in woods; and usually builds on an old crow's nest, which it enlarges, and lines with wool and other soft materials. It lays two or three eggs, which are sometimes perfectly white, sometimes spotted with yellow. The cock-buzzard will hatch and bring up the young if the hen is killed. The young keep company with the old ones for some little time after they quit the nest; which is not usual with other birds of prey who always drive away their brood as soon as they can fly. The buzzard is very inactive, and is much less in motion than other hawks; remaining perched on the same bough for the greatest part of the day, and dwelling at most times near the same place. It feeds on birds, rabbits, moles, and mice; it will also eat frogs, earthworms, and insects. This bird is subject to some variety in its colour. Some have the breast and belly of a brown colour, and are only marked across the craw with a large white crescent; but usually the breast is of a yellowish white, spotted with rust-coloured spots, pointing downwards; the back of the head, neck, and coverts of the wings, are of a deep brown, edged with a pale rust-colour: the middle of the back covered only with a thick white down. The tail is barred with black and ash-colour, and sometimes ferruginous.

12. The *columbarius*, or pigeon-hawk of Catesby, weighs about six ounces. The bill is black at the point, and whitish at the base: the iris of the eye is yellow; the base of the upper mandible is covered with a yellow cere of wax: all the upper part of the body, wings, and tail, are brown. The anterior vanes of the quill-feathers have large red spots. The tail is marked with large regular transverse white lines; the throat, breast, and belly, are white, mixed with brown: the small feathers that cover the thighs reach within half an inch of the feet, and are white, with a tincture of red, beset with long spots of brown; the legs and feet are yellow. It inhabits America, from Hudson's-bay as low as South Carolina.

13. The *palumbarius*, with black wax edged with yellow, yellow legs, a brown body, the prime feathers of the tail marked with pale streaks, and the eye-brows white. It is the gos-hawk of Ray, and was formerly in high esteem among falconers, being flown at cranes, geese, pheasants, and partridges. It breeds in Scotland, and builds its nest in trees. It is destructive to game, and dashes through the woods after its quarry with vast impetuosity; but if it cannot catch the object of its pursuit almost immediately, desists, and perches on a bough till some new game presents itself. This species is common in Muscovy and Siberia.

Besides these we may mention the lithofalco, or stone falcon, which inhabits many parts of Europe, and is about a foot long; the bill blueish-ash; irides yellow; two middle tail-feathers uniform, the rest barred with brown: the gallicus or French eagle, so called from its being found chiefly in France, about two feet long, feeds on rats, mice, and frogs; it builds its nest mostly on the ground, the irides yellow; tail feathers white with brown transverse stripes, brown at the tips and edges; claws grey: the latter inhabits Europe, Tartary in Asia, and many parts of North America; it is two feet long, patient of cold; used in hunting the white heron: the head pale brown; wing-coverts and primary quill feathers with transverse white lines; tail brown, with oval transverse red spots on the sides; legs feathered to the toes: and the magnirostris, or great billed falcon, found in Cayenne, a little larger than the sparrow-hawk; legs shorter; bill longer, thicker, black; irides orange; feathers above and on the breast brown edged with rusty; claws black.

There are some other species distinguished by ornithologists. Among these are two described by Mr. Bruce; of which one deserves particular notice, as being not only the largest of the eagle kind, but supposed to be the largest bird that flies. He calls it the golden eagle; by the natives it is vulgarly called abon duchn, or father long-beard.

FALCONRY, the art of training all manner of hawks, but more especially the larger sort, called falcons, to the exercise of hawking.

FALL, in the sea language, that part of the rope of a tackle, which is hauled upon.

Also when a ship is under sail, and keeps not so near the wind as she should do, they say she falls off.

FALLOPIAN *tubes*, two canals of a tortuous figure, but approaching to a conic form, joined to the fundus of the uterus, one on each side.

FALSE, in music, an epithet applied by theorists to certain chords, called false, because they do not contain all the intervals appertaining to those chords in their perfect state; as a fifth, consisting of only six semitonic degrees, is denominated a false fifth.

FALX, in anatomy, a process of the dura mater, placed between the two hemispheres of the brain, and resembling a reaper's sickle.

FAMES *canina*, an excessive appetite. See Bulimy.

FAMILY, denotes the persons that live together in one house, under the direction of one head or chief manager. It also signifies the kindred or lineage of a person, and is used by old writers for a hide or portion of land sufficient to maintain one family.

Family, in natural history, a term used by authors to express any order of animals, or other natural productions of the same class.

FAN, an instrument used in winnowing corn.

FARINA, a term given to the pulverulent and glutinous part of wheat and other seeds, obtained by grinding and dressing.

FARM or Ferm, signifies the chief messuage in a village, or any large messuage to which land belongs, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

FARRIER, is the designation of the smith who devotes his attention chiefly to shoeing horses, and to curing them of all kinds of diseases. It was probably owing to the opportunities afforded to the smiths, while shoeing horses, of observing the various diseases of the foot, and consequently of haranguing on the subject, that they, in time, acquired an undue reputation for perfect ability in not only that particular, but for a general knowledge of whatever related to the animal at large.

FARRIERY, the art and profession of the farrier, which have comprehended, from the earliest even to the present period, the medical and surgical care of the horse, as well as that of manufacturing and fitting him with shoes. These men, as labourers of iron, were originally termed ferrers, or ferriers, from the Latin word *ferrum*, iron, and their craft ferriery; which word has since, either by a very usual corruption or improvement of language, been changed to farriery. This term remains yet in general use to its fullest extent, and not inaptly; since notwithstanding the laudable attempts of many enlightened men at various periods, our blacksmiths form a very large majority of horse surgeons and physicians. Nor is such defect peculiar to this country, but prevails throughout Europe.

On the establishment of a college, about fourteen years since, for the instruction of pupils in animal medicine and surgery, we imported from France the term *veterinary*, and the veterinary art has been since substituted for farriery by practitioners of liberal education. The supposed derivation of the term veterinary is from the participle *vectum*, of the Latin word *veho*, to carry; *quasi*, vecterinary, thence applied to the care of animals which carry.

For a more particular view of the subject of farriery the reader is referred to the article Veterinary Art.

FASCES, in Roman antiquity, axes bound up together with rods or staves, and carried before the Roman magistrates as a badge of their authority and office.

FASCIÆ, in astronomy, certain parts on Jupiter's body resembling belts or swaths. They are more lucid than the rest of that planet, and are terminated by parallel lines, sometimes broader, and sometimes narrower.

FASCINES, in fortification, faggots of small wood of about a foot diameter, and six feet long, bound in the middle, and at both ends.

FASCIOLA, in zoology, the *fluke* or gourd worm: a genus of insects of the order of vermes intestinæ; of which the characters are these: The body is flattish, and has a vent-hole at the extremity and on the belly. There are several species. 1. The hepatica, or liver-fluke, grows to two-thirds of an inch in length, though it is more usually met with not half that size. It bears some resemblance to the seed of the common gourd, whence it has acquired the name of the gourd worm. It is found in fresh waters, in ditches, at the roots of stones, sometimes in the intestines, and often in the substance of the other viscera in quadrupeds. It often infests the liver of sheep, and on that account is called hepatica. Bags with salt in them, placed in the fold, that the sheep may lick them, is a good remedy. 2. The intestinalis, or intestinal fluke, inhabits the intestines of fresh-water fish, especially the bream. 3. The barbata, is white, with transverse papillæ in the mouth. It is of an oblong shape, and about the size of a cucumber-seed.

FAT, in anatomy, an oleaginous or butyraceous matter, secreted from the blood, and filling up the cavity of the adipose cells.

Fat, in chemistry. See Oil.

FATA *Morgana*, a very remarkable aerial phenomenon, which is sometimes observed from the harbour of Messina and adjacent places, at a certain height in the atmosphere. The name, which signifies the Fairy Morgana, is derived from an opinion of the superstitious Sicilians, that the whole spectacle is produced by fairies, or such-like visionary invisible beings. The populace are delighted whenever it appears; and run about the streets shouting

for joy, calling every body out to partake of the glorious sight.

This singular meteor has been described by various authors; but the first who mentioned it with any degree of precision was father Angelucci, whose account is thus quoted by Mr. Swinburne in his Tour through Sicily: "On the 15th of August, 1643, as I stood at my window, I was surprised with a most wonderful delectable vision. The sea that washes the Sicilian shore swelled up, and became, for ten miles in length, like a chain of dark mountains; while the waters near our Calabrian coast grew quite smooth, and in an instant appeared as one clear polished mirror, reclining against the ridge. On this glass was depicted in chiaro-scuro, a string of several thousand of pilasters, all equal in altitude, distance, and degree of light and shade. In a moment they lost half their height, and bent into arcades, like Roman aqueducts. A long cornice was next formed on the top, and above it rose castles innumerable, all perfectly alike. These soon split into towers, which were shortly after lost in colonnades, then windows, and at last ended in pines, cypresses, and other trees, even and similar. This is the Fata Morgana, which for twenty-six years I had thought a mere fable."

To produce this pleasing deception, many circumstances must concur, which are not known to exist in any other situation. The spectator must stand with his back to the east, in some elevated place behind the city, that he may command a view of the whole bay; beyond which the mountains of Messina rise like a wall, and darken the back ground of the picture. The winds must be hushed, the surface quite smooth, the tide at its height, and the waters pressed up by currents to a great elevation in the middle of the channel. All these events coinciding, as soon as the sun surmounts the eastern hills behind Reggio, and rises high enough to form an angle of 45 degrees on the water before the city, every object existing or moving at Reggio will be repeated a thousandfold upon this marine looking-glass; which, by its tremulous motion, is in a manner cut into facets. Each image will pass rapidly off in succession as the day advances, and the stream carries down the wave on which it appeared. Thus the parts of this moving picture will vanish in the twinkling of an eye. Sometimes the air is at that moment so impregnated with vapours, and undisturbed by winds, as to reflect objects in a kind of aerial screen, rising about 30 feet above the level of the sea. In cloudy heavy weather they are drawn on the surface of the water, bordered with fine prismatical colours.

FATHOM, a long measure containing six feet, chiefly used at sea for measuring the length of cables and cordage.

FEATHER, in physiology, a general name for the covering of birds: it being common to all the animals of this class to have their whole body, or at least the greatest part of it, covered with feathers or plumage.

Feathers make a considerable article of commerce, particularly those of the ostrich, heron, swan, peacock, goose, &c. for plumes, ornaments of the head, filling of beds, writing-pens, &c. Geese are plucked in some parts of Great Britain five times in the year; and in cold seasons many of them die by this barbarous custom. Those feathers that are brought from Somersetshire are esteemed the best, and those from Ireland the worst.

Eider down is imported from Denmark; the ducks that supply it being inhabitants of Hudson's-bay, Greenland, Iceland, and Norway. All the islands west of Scotland, breed numbers of these birds, which turn out a profitable branch of trade to the poor inhabitants. Hudson's-bay also furnishes very fine feathers, supposed to be of the goose kind. The down of the swan is brought from Dantzic. The best method of curing feathers is to lay them in a room, exposed to the air and sun; and when dried, to put them in bags, and beat them well with poles to get off the dirt.

Feathers, when chemically analysed, seem to possess very nearly the same properties with hair. According to Mr. Hatchett, the quill is composed chiefly of coagulated albumen, without any traces of gelatine.

FEATHER-*mill*, in the salt-works, the partition in the middle of the furnace, which it divides into two chambers.

FEATHER-*edged*, among carpenters, an appellation given to planks or boards which have one side thicker than the other.

FECES. The excrementitious matter of animals, evacuated per anum, consists of all that food which cannot be employed for purposes of nutrition, considerably altered, at least in part, and mixed or united with various bodies employed during digestion to separate the useless part of the food from the nutritious.

The constituents of human feces, according to the recent analysis of Berzelius, are the following:—

Water . . :	73.3
Vegetable and animal remains	7.0
Bile	0.9
Albumen	0.9
Peculiar extractive matter . .	2.7
Salts	1.2
Slimy matter, consisting of resin of bile, peculiar animal matter, and insoluble residue	14.0
	100.0

The salts were to one another in the following proportions:—

Carbonate of soda, ...	0.9
Muriate of soda, ...	0.1
Sulphate of soda, ...	0.05
Ammon. phos. magn. . . .	0.05
Phosphate of lime	0.1
	1.20

To MM. Fourcroy and Vauquelin we owe what precise knowledge we possess, regarding the excrements of birds, in which they found a large quantity of uric acid. This forms the white, and nearly crystaline portion. It does not proceed from the fœcal matter properly so called, but from the urine, which in this class of animals is mixed with the excrement, by the nature of their organization. This acid is easily extracted, by breaking the excrement with alkaline water, filtering the liquor, and pouring into it muriatic acid.

FEE, in law, *feudum*, *beneficium*, all land in England is in the nature of a feud or fee, and subject to the original conditions of the grant, which is supposed to come from the crown: but now that distinction is very immaterial.

FEE *simple*, is an estate of inheritance whereby a person is seised of lands, tenements, or hereditaments, to hold to him and his heirs for ever, generally, absolutely, and entirely; without mentioning what heirs, but referring that to his own pleasure, or the disposition of the law.

FEELERS, in natural history, a name used by some for the horns of insects. See ENTOMOLOGY.

FEELING, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities.

This sense is the coarsest, but at the same time the surest of all others; it is besides the most universal. We see and hear with small portions of our body, but we feel with all. Nature has bestowed that general sensation wherever there are nerves, and they are every where, where there is life.

The object of feeling is every body that has consistency or solidity enough to move the surface of our skin. It was necessary to perfect feeling, that the nerves should form small eminences, because they are more easily moved by the impression of bodies, than a uniform surface.

FELAPTON, in logic, one of the six moods of the third figure of syllogisms, wherein the first proposition is a universal negative, the second an universal affirmative, and the third a particular negative.

FELIS, *cat*, in zoology, a genus of the mammalia class, belonging to the order of feræ. The generic character is: front teeth six, the intermediate ones equal; grinders three on each side; tongue aculeated backwards; claws retractile.

1. *Felis leo*, lion. The lion is principally an inhabitant of Africa, but is also found in the hotter regions of Asia. It is, however, in the interior of Africa that he exerts his greatest ravages, and reigns superior among the weaker quadrupeds. A lion of the largest size has been found to measure about eight feet from the nose to the tail, and the tail itself about four feet; the general colour is a pale tawny, still paler or more inclining to white beneath: the head is very large, the ears rounded, the face covered with short or close hair, the upper part of the head, the neck, and shoulders coated with long shaggy hair, forming a pendent mane; on the body the hair is short and smooth, the tail is terminated by a tuft of blackish hair. The lioness, which is smaller than the lion, is destitute of the mane, and is of a whiter cast beneath. The lion, like the tiger, frequently conceals himself in order to spring on his prey, bounding to the distance of a great many feet, and seizing it with his claws. His strength is prodigious: it has even been affirmed, that a single stroke of his paw is sufficient to break the back of a horse; and that he carries off with ease a middle sized buffalo. The roaring of the lion, when in quest of prey, resembles the sound of distant thunder; and, being re-echoed by the rocks and mountains, appals the whole race of animals, and puts them to sudden flight; but he frequently varies his voice into a hideous scream or yell: he is supposed to be destitute of a fine scent, and to hunt by the eye alone. The lion is commonly said to devour as much as will serve him for two or three days, and when satiated with food, to remain in a state of retirement in his den, which he seldom leaves, except for the purpose of prowling about for his prey.

The lioness is said to bring forth in the spring, in the most sequestered places, and to produce but one brood in the year.

2. *Felis tigris*, tiger, is a native of the warmer parts of Asia, and is principally found in India and the Indian islands. The species extends, however, as far as China and Chinese Tartary, the lake Ural, and the Altaic mountains. Its colour is a deep tawny, or orange-yellow, the face, throat, and under side of the belly, being nearly white; the whole is traversed by numerous long black stripes, forming a bold and striking contrast with the ground-colour. About the face and breast the stripes are proportionably smaller than on other parts; the tail is annulated with black, and is shorter than the body.

In its general size the tiger is inferior only to the lion, and has been seen even larger.

Of so fierce and sanguinary a disposition is the tiger, as to surpass in rapacity every other wild beast, and it is therefore considered as the most dreadful scourge of the hotter regions of Asia. His method of seizing his prey is by concealing himself from view, and springing with a horrible roar on his victim, which he carries off and tears in pieces, after having first sucked out the blood. The voice of the tiger, in the act of springing on his prey, is said to be hideous beyond conception. Even a buffalo has been thus seized by a tiger, and carried off with such seeming ease, as to appear scarcely an impediment to the animal's flight.

The tiger has been known to attack even a lion, and both animals have perished in the conflict. The tigress produces four or five young at a litter: she is at all times furious, but her rage rises to the utmost extremity when robbed of her young. She then braves every danger, and pursues her plunderers, who are often obliged to release one in order to retard her motion. She stops, takes it up, and carries it to the nearest cavern, but instantly returns and renews her pursuit, even to the very gates of buildings or the edge of the sea; and when her hope of recovering them is lost, she expresses her agony by hideous howlings, which excite terror wherever they reach.

3. *Felis pardus*, panther. Next to the tiger, the panther is the most conspicuous species in this genus, measuring about six feet and a half, and sometimes nearly seven feet from nose to tail, which is itself about three feet long. The colour of the panther is a beautiful tawny yellow, thickly marked with roundish black spots, and there is commonly a central spot in each circle. On the face and legs the spots are single, and along the top of the back is a row of oblong spots. The breast and belly are white; the former marked with transverse dusky stripes, the latter and the tail with large irregular black spots.

The panther is principally found in Africa, and is to that country what the tiger is to Asia, with this alleviating circumstance, that it is supposed to prefer the destruction of other animals to that of man. Its manner of seizing

its prey resembles that of the tiger, lurking near the sides of woods, &c. and darting forward with a sudden spring. It is of a highly ferocious nature, and scarcely to be tamed.

4. *Felis leopardus*, the leopard, is best distinguished from the panther by its paler yellow colour, its small size, and the somewhat closer disposition of the spots. The general length of this species from nose to tail, is four feet, of the tail two and a half. It is a native of Senegal and Guinea, as well as of many other parts of Africa; it also occurs in several parts of Asia, viz. in Persia, India, China, &c. In its manners it resembles the panther.

A variety of this species of a dusky black, marked with spots of a deeper or more glossy black, and perfectly resembling in disposition those of the common leopard, is found in Bengal.

5. *Felis jubata*, the hunting leopard, is about the size of a large greyhound, and of a long make, with narrow chest, and long legs. It is a native of India, where it is said to be tamed, and used for the chase of antelopes and other animals. If it happen to miss its prey, it returns immediately at the call of its master.

6. *Felis uncia*, the ounce, is scarcely inferior in size to the leopard. Its colour is dull white, with a slight yellowish or tawny cast, and the whole is scattered over with spots. In its general form the animal seems much allied to the leopard. It seems not to have been distinctly described by any modern author till the time of Buffon; but it is supposed to have been known to the ancients, and to have been the smaller panther of Oppian, and the panthera of Pliny. It is a native of several parts of Africa and Asia.

7. *Felis onca*, the Brazilian tiger, is a native of the hotter parts of South America, and is considered as a very fierce and destructive animal. Its manners are said to resemble those of the tiger, lying in ambush for its prey. It is about the size of a wolf, or even larger. Its ground-colour is a pale brownish-yellow, variegated on the upper parts with streaks and markings of black, the top of the back being marked with long interrupted stripes, and the sides with rows of regular open marks.

8. *Felis pardalis*, ocelot. The ocelot or pardalis is certainly one of the most beautiful of the present genus. Mr. Pennant describes it as about four times the size of a large cat. The ground-colour of the male is a bright reddish-tawny above, nearly white on the lower part. Several large stripes, of a deeper or richer tinge than the ground-colour, are disposed over the upper parts of the body: these stripes are edged with black, and have also several differently shaped black spots in the middle part. The head is streaked and spotted with black, and the upper as well as under parts of the limbs and the belly marked in a beautiful manner with small and numerous round spots; the tail is patched or spotted also. The colours of the female are less vivid, and more inclining to ash-colour. This is an extremely ferocious animal, and inhabits the hotter parts of South America.

9. *Felis puma*. The puma is the largest of the American beasts of prey, measuring five feet or more from nose to tail, the tail itself about two feet eight inches. It is a long-bodied animal, and stands high on its legs. Its colour is a pale brownish-red, with a slight dusky cast on some parts; the chin is white; the breast and belly ash-coloured; and the insides of the legs are of the same colour; the tail of a dusky-ferruginous tinge, with a black tip. It is a native of many parts of America both north and south, occurring from Canada to Brazil.

10. *Felis discolor*, black tiger. This, like the former species, is a native of America, and is considered as a very destructive animal. It is about the size of a large dog, and is entirely of a brownish-black colour on the upper parts, and pale-grey or whitish beneath.

11. *Felis tigrina*, margay. The margay is a native of South America, and is about the size of a common cat. The ground-colour is a bright tawny; the face striped with black; the shoulders and body marked both with stripes and large black spots; the tail is long, and marked with black and grey. It resides principally on trees, preying on birds: it is said to breed in the hollows of trees, and is very fierce and untameable.

12. *Felis capensis*, the Cape cat, inhabits the neighbourhood of the Cape of Good Hope. In its manners it seems to resemble the common cat, frequenting trees, and preying on smaller animals.

13. *Felis manul*. This species inhabits the middle part of northern Asia. It is of the size of a fox, and is of a strong and robust make. Its colour is tawny, the tail is longer than that of a domestic cat, and is thickly beset with hair, and encircled with ten black rings.

14. *Felis catus*. The cat, in a state of natural wildness, and from which are supposed to have proceeded all the varieties of the domestic cat, is a native of the northern regions of Europe and Asia. In its natural state it differs in some slight particulars from the domestic animal, having a shorter tail in proportion, a flatter and larger head, and stronger limbs. The colour is commonly a pale yellowish-grey, with dusky stripes and variegations, those on the back-running lengthwise, those on the sides transversely and with a curved direction: the tail is annulated with alternate circles of blackish-brown and dull white; the tip of the nose and the lips are black. Even wild cats, however, appear to differ in their shades of colour in different parts of Europe.

The manners of the wild cat resemble those of the lynx, and several others of this genus, living in woods, and preying on young hares, on birds, and a variety of other animals, which it seizes by surprise. It breeds in the hollows of trees, and produces about four at a birth. Of all the above varieties, the Persian and the Angora are the most remarkable: the latter variety has one eye blue, the other yellow; a particularity which takes place in some specimens of the common white cat. It is also observable, that the white variety of the cat is sometimes perfectly deaf.

No animal exhibits a greater degree of maternal tenderness than the cat. She even possesses a propensity to nurse with tenderness the young of a different individual; and will

commonly suckle and nurse any young kitten that is newly introduced to her.

The fur of the cat, being generally clean and dry, readily yields electric sparks when rubbed; and if a clean and perfectly dry domestic cat is placed, in frosty weather, on an insulated stool, and rubbed for a certain space in contact with the wire of a coated phial, it will be effectually charged by this method.

15. *Felis serval.* The serval is a native of India and Tibet, and is an extremely fierce and rapacious animal. It resides principally among trees, leaping with great agility from one tree to another, and pursuing birds, &c. Its shape is thick and strong; its general colour is fox-red or ferruginous, with the throat, abdomen, and insides of the legs, yellowish-white.

16. *Felis chaus,* is an inhabitant of the marshy tracts on the western side of the Caspian Sea, and in the Persian provinces of Ghilan and Masenderen. In manners, it agrees with the wild cat. Its general length is about two feet six inches from the nose to the tail. The colour of this species is a dusky yellowish-brown; the tail is tipped with black, and the ears are tufted with black hairs.

.7. *Felis rufa,* bay lynx. This species is about twice the size of a large cat, and is a native of North America. Its colour is a bright bay, obscurely marked with small dusky spots. The hair is shorter and smoother than that of the common lynx.

18. *Felis caracal,* the caracal or Persian lynx, is a native both of Asia and Africa; in some parts of Persia it is tamed and made use of in the chase. It is an animal of great strength and fierceness. It is used not only in the chase of the smaller quadrupeds, but of the larger kinds of birds, such as herons, cranes, pelicans, &c. The caracal is about the size of a fox, but of a much stronger make its colour is a pale reddish-brown, whitish beneath.

19. *Felis lynx,* the common lynx, is found in all the colder regions of Europe, Asia, and America, residing in thick woods, and preying on hares, deer, birds, and other animals. The general size of the lynx is that of a middling dog. In colour the lynx varies, but is generally of a pale-grey, with a very slight reddish tinge; the back and whole upper parts are obscurely spotted with blackish marks. The throat, breast, and belly, are white; the tail white, with a black tip; the ears tipped with pencils of long black hair.

FELLOES, in fortification, are six pieces of wood, which, with the addition of a nave and twelve spokes, make the wheel of a gun-carriage.

FELLOWSHIP, or COMPANY, in arithmetic, is when two or more join their stocks, [illegible] rther, dividing their gain or loss [illegible]

Fellowship is either with or without time. Questions without time, or the single rule of fellowship, as it is frequently called, are wrought by the following proportion:

As the whole stock, to the whole gain or loss, so is each man's particular stock, to his particular gain or loss.

FELLOWSHIP *with time,* usually called the *double rule of fellowship,* because every man's money is to be considered with relation to the time of its continuance in the joint stock. It is worked thus: multiply each man's stock by the respective time he puts it in for, and add all the products; the total of which must be the first number through all the statings; the gain or loss the second, as before; and each man's particular stock, multiplied by its time, the third.

FELO *de se,* in law, one who is felon of himself; i.e. being of sound memory, and of the age of discretion, or 14 years, kills himself. All his chattels, real and personal, are forfeited to the crown, when it is found by the Coroner that he is *felo de se.* A will, therefore, made by him, is void as to his personal estate, but not as to his land or real estate; nor is his wife barred of her dower. If a man and his wife are possessed of a term, and the man commit suicide, the term is forfeited, and the wife shall not have it by survivorship. The coroner must find the fact upon an inquest, on view of the body, in order to vest the goods in the king.

FELONY, in the general acceptation of law, comprises every species of crime which occasioned at common law the forfeiture of lands or goods. This generally happens in those for which a capital punishment either was or is liable to be inflicted; for those felonies to which the benefit of clergy extends, were anciently punished with death in lay or unlearned offenders; though now, by the statute law, that punishment is for the first offence universally remitted.

FELSPAR, one of the essential component parts of granite, and is itself a compound substance; silica and alumina being the chief ingredients. It generally contains a little lime and pot-ash, and is often coloured with minute portions of oxide of iron. It is softer than quartz, but harder than glass, and is fusible by the blow-pipe. For the different species of this substance. See MINERALOGY.

FELT, in commerce, a sort of stuff, deriving all its consistence merely from being fulled or wrought with lees and size, without either spinning or weaving. Felt is made either of wool alone, or of wool and hair.

FELTING. See HATMAKING.

FELUCCA, in sea affairs, a little vessel with six oars, frequent in the Mediterranean, which has this peculiarity, that its helm may be applied either in the head or stern as occasion requires.

FEME *covert,* a married woman, so called from being under the cover, protection, and influence of her husband.

FEME *sole,* a single or unmarried woman A feme sole is liable to perform parish offices, the act only requiring the person to be a substantial householder, without reference to sex.

FEMINEUS *flos,* a female flower. By this name Linnæus denominates a flower which is furnished with the pistillum, or female organ of generation, but wants the stamina or male organ. Female flowers may be produced apart from the male, either on the same root or on distinct plants. The birch and mulberry are examples of the first case; willow and poplar of the second.

FEN, a place overflowed with water, or abounding with bogs.

Fens are either made up of a congeries of bogs, or consist of a multitude of pools or lakes with dry spots of land intermixed, like so many little islands.

FENCE, in country affairs, a hedge, wall, ditch, bank, or other inclosure, made around gardens, woods, corn-fields, &c.

FENCING, the art of making a proper use of the sword, as well for attacking an enemy, as for defending one's self. It is necessary in acquiring this difficult art to use foils, or small thin swords, which being blunted at the points, and bending readily, prevents accidental wounds.

FEOD or **Feud**, is the right which a vassal had in lands or other property belonging to his Lord, to use them, and appropriate the profits thereof hereditarily, rendering to the lord such duties and services as belong to the military tenure; the property of the soil, &c. always remaining to the lord. From this arose the feudal system, which about twelve centuries ago was universally received in Europe.

FEOFFMENT, in law, may be defined to be the gift of any corporeal hereditament to another. He that so gives or enfeoffs is called the feoffer; and the person enfeoffed is denominated the feoffee.

FERÆ, in zoology, an order of quadrupeds, the distinguishing characters of which are, that all the animals belonging to it have fore-teeth conic, usually six in each jaw; tusks longer; grinders with conical projections; feet with claws; claws subulate; food, carcases, and preying on other animals.

Feræ *naturæ*. Animals of a wild nature are those in which a man has not an absolute but only a qualified and limited property, which sometimes subsists, and at other times does not subsist.

FERMENTATION. When aqueous combinations of vegetable or animal matter are exposed to ordinary atmospherical temperatures, they speedily undergo spontaneous changes, to which the generic name of *fermentation* has been given. Animal liquids alone, or mixed with vegetables, speedily become sour. The act which occasions this alteration is called acetous fermentation, because the product is, generally speaking, acetic acid, or vinegar. But when a moderately strong solution of saccharine matter, or saccharine matter and starch, or sweet juices of fruits, suffer this intestine change, the result is an intoxicating liquid, a beer, or wine; whence the process is called vinous fermentation. An ulterior change to which all moist animal and vegetable matter is liable, accompanied by the disengagement of a vast quantity of fetid gases, is called the putrefactive fermentation.

Each of these processes goes on most rapidly at a somewhat elevated temperature, such as 80° or 100° F. It is for these reasons that, in tropical countries, animal and vegetable substances are so speedily decomposed.

As the ultimate constituents of vegetable matter are oxygen, hydrogen, and carbon; and of animal matter, the same three principles with azote, we can readily understand that all the products of fermentation must be merely new compounds of these three or four ultimate constituents.

All vegetable substances containing saccharine matter are susceptible of the vinous fermentation. During the process of fermentation, the liquor first becomes turbid and viscid; an intestine motion and an increase of bulk take place: air bubbles are discharged from the whole mass, bursting forth with a hissing noise, and forming a beautiful froth on the surface. The sweetness of the liquor disappears, and it acquires a pungent taste. After a certain time these appearances cease; a sediment is deposited, and the liquor becomes perfectly clear. It is now found to have acquired a brisk taste, a vinous flavour, and an intoxicating quality.

When it is required to preserve fermented liquors in the state produced by the first stage of fermentation, it is usual to put them into casks before the vinous process is completely ended; and in these closed vessels a change very slowly continues to be made for many months, and perhaps for some years.

But if the fermentative process be suffered to proceed in open vessels, more especially if the temperature be raised to 90 degrees, the acetous fermentation comes on. In this, the oxygen of the atmosphere is absorded; and the more speedily in proportion as the surfaces of the liquor are often changed by lading it from one vessel to another. The usual method consists in exposing the fermented liquor to the air in open casks, the bung-hole of which is covered with a tile to prevent the entrance of the rain. By the absorption of oxygen which takes place, the inflammable spirit becomes converted into an acid. If the liquid be then exposed to distillation, pure vinegar comes over instead of ardent spirit.

When the spontaneous decomposition is suffered to proceed beyond the acetous process, the vinegar becomes viscid and foul; air is emitted with an offensive smell; volatile alkali flies off; an earthy sediment is deposited; and the remaining liquid, if any, is mere water. This is the putrefactive process.

The fermentation by which certain colouring matters are separated from vegetables, as in the preparation of woad and indigo, is carried much farther, approaching the putrefactive stage.

It is not clearly ascertained what the yeast or ferment performs in this operation. It seems probable, that the fermentative process in considerable masses would be carried on progressively from the surface downwards; and would, perhaps, be completed in one part before it had perfectly commenced in another, if the yeast, which is already in a state of fermentation, did not cause the process to begin in every part at once.

FERRARIA, a genus of the triandria order, in the gynandria class of plants, and in the natural method ranking under the sixth order ensatæ. There are two species, natives of the Cape of Good Hope and Mexico.

FERRUGINOUS, any thing partaking of iron, or that contains particles of that metal. It is particularly applied to certain mineral springs, whose waters are impregnated with the particles of iron generally termed chalybeats.

FERULA, *fennel giant*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. There are nine species, all of them herbaceous perennials, rising from three to ten or twelve feet high, with yellow flowers.

FEVER, *febris*, in medicine, a disease, or rather class of diseases, whose characteristic is a preternatural heat felt through the whole body, or at least the principal parts of it.

FIBRE, in anatomy, a perfectly simple body, or at least as simple as any thing in the human structure, being fine and slender like a thread, and serving to form other parts. Hence some fibres are hard, as the bony ones; and others soft, as those destined for the formation of all the other parts.

FIBRINA, is that substance which constitutes the fibrous part of the muscles of animals. If a quantity of blood, newly drawn from an animal, be allowed to remain at rest for some time, a thick red clot gradually forms in it, and subsides. Separate this clot from the rest of the blood, put it into a linen cloth, and wash it repeatedly in water till it ceases to give out any colour or taste to the liquid; the substance which remains after this process, is denominated fibrina. Fibrina is of a white colour, has no taste nor smell, and is not soluble in water nor in alcohol.

FIBROLITE. Colours white and grey; crystallized in rhomboidal prisms, the angles of whose planes are 80° and 100°. It is glistening internally. Principal fracture uneven. Harder than quartz. Sp. gr. 3.214. Its constituents are alumina 58.25, silica 38, iron and loss 3.75. It is found in the Carnatic.

FICUS, a genus of the triœcia order, in the polygamia class of plants, and in the natural method ranking under the 53d order, scabridæ. There are 56 species, of which the following are the most remarkable.

1. *Ficus indica*, or banian-tree, is a native of several parts of the East Indies. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves ending in acute points.

The banian tree, or Indian fig, is perhaps the most beautiful of nature's productions in that genial climate. Some of these trees are of amazing size and great extent, as they are continually increasing, and, contrary to most other things in animal and vegetable life, seem to be exempted from decay. Every branch from the main body throws out its own roots; at first, in small tender fibres, several yards from the ground: these continually grow thicker until they reach the surface; and there striking in, they increase to large trunks, and become parent trees, shooting out new branches from the top: these in time suspend their roots, which, swelling into trunks, produce other branches; thus continuing in a state of progression as long as the earth contributes its sustenance.

Near these trees the most esteemed pagodas are generally erected; under their shade the Brahmins spend their lives in religious solitude; and the natives of all casts and tribes are fond of recreating in the cool recesses, beautiful walks, and lovely vistas of this umbrageous canopy, impervious to the hottest beams of a tropical sun.

2. The *sycamorus*, or sycamore of scripture. According to Hasselquist, this is a huge tree, the stem being often 50 feet round. The fruit is pierced in a remarkable manner by an insect. The place affected becomes black; the fleshy substance in the middle of the calyx, for the breadth of a quill, is corroded · and the male blossoms, which are nearest to the bare side, appear naked, opening a way for the insect, which makes several furrows in the inside of the fruit, but never touches the stigmata, though it frequently eats the germen.

3. The *carica*, or common fig, with an upright stem branching 15 or 20 feet high, with large palmated or hand-shaped leaves. Of this there are a number of varieties.

FIDDLE. See Violin.

FIELD, in heraldry, is the whole surface of the shield. It is the ground on which the colours, bearings, metal, furs, charges, &c. are represented.

Field-*book*, in surveying, that in which the angles, stations, distances, &c. are set down. See Surveying.

Field-*pieces*, small cannon, from three to twelve pounders, carried along with an army in the field.

Field-*works*, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

FIFE, a shrill wind-instrument of the martial kind, consisting of a short narrow tube, with holes disposed along the side, for the regulation of its tones.

FIFTEENTH, an ancient tribute or tax laid upon cities, boroughs, &c. throughout all England, and so termed because it amounted to a fifteenth part of what each city or town had been valued at: or it was a fifteenth of every man's personal estate according to a reasonable valuation. In Doomsday-book, there are certain rates mentioned for levying this tribute yearly. The present property-tax seems a revival of this ancient system.

Fifteenth, an interval consisting of two octaves.

FIFTH, in music, a distance comprising four diatonic intervals, *i. e.* three tones and a half.

Fifth, *sharp*. The sharp fifth is an interval consisting of eight semitones.

FIG. See Ficus.

FIGURATE *numbers*, such as do or may represent some geometrical figure, in relation to which they are always considered; as triangular, pentagonal, pyramidal, &c. numbers.

FIGURE, in conic sections, according to Apollonius, is the rectangle made under the latus rectum and transversum in the hyperbola and ellipsis.

Figure, in fortification, the plan of any fortified place, or the interior polygon, which, when the sides and angles are equal, is called a regular, and when unequal, an irregular figure.

Figure, in geometry, the superficies included between one or more lines, is denominated either rectilinear, curvilinear, or mixed, according as the extremities are bounded by right lines, curve lines, or both.

Figure, in grammar, a deviation from the natural rules of etymology, syntax, and prosody, either for brevity, elegance, or harmony.

Figure, in logic, denotes a certain order and disposition of the middle term in any syllogism.

Figure, in painting and designing, denotes the lines and colours which form the representation of any animal, but more particularly of a human personage.

Figure, in rhetoric, is a manner of speaking different from the ordinary and plain way, and more emphatical; expressing a passion, or containing a beauty. See Rhetoric.

FILACER, or *filizer*, an officer of the Court of Common Pleas, so called because he files those writs whereon he makes out process.

FILAGO, a genus of the polygamia necessaria order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are seven species, commonly known by the name of cudweed, natives of most parts of Europe, herbaceous, most of them annual.

FILAMENTS, vegetable, form a substance of great use in the arts and manufactures, furnishing thread, cloth, cordage, &c. For these purposes the filamentous parts of hemp and flax are employed among us. Different vegetables have been employed in different countries for the same uses. In some parts of Sweden a strong cloth is said to have been prepared from the stalks of hops. These have been tried here, but without success. Vegetable filaments, and the thread or cloth prepared from them, differ remarkably from wool, hair, silk, and other animal productions, particularly in their disposition to imbibe colouring matters; sundry liquors, which give a beautiful and durable dye to those of the animal, giving no stain at all to those of the vegetable kingdom.

FILARIA, a genus of insects of the order intestina. There are several species, some infesting different animals and insects. The medinensis is the most remarkable species; it inhabits the Indies, and is frequent in the morning dew, whence it enters the naked feet of the slaves, and creates the most troublesome itchings, accompanied with inflammation and fever.

FILBERT. See Corylus.

FILE, among mechanics a tool used metal, &c. in order to smooth, polish, or cut.

This instrument is of iron, or forged steel, cut in little furrows, with chisels, and a mallet, in a certain direction, and of a certain depth, according to the grain or touch required. Files are cut by the hand, although several engines have been invented for the purpose. Engines, however much they may facilitate the process, do not answer, as appears from the circumstance of their not being used in any file manufactory. This is satisfactorily accounted for by Mr. Nicholson, who some years ago obtained a patent for an improvement of this kind. He says:—

The principal requisites in a machine for file-cutting are, that the file should be steadily supported, and the chizel adapted to the face without any unequal bearing. Files are however, for the most part, cut by hand; and the chief reasons are, 1. The cut by hand is, from its very nature, exactly of the depth the bur demands; whereas, in a machine, if the stroke be not nicely adapted to the shift, the file may be either shallow-cut, or its bar may be thrown too close by an over heavy stroke; and, 2. In machine cut files, there must always be a piece left at the beginning, at each corner, which requires to be cut off before hardening. This may be remedied in the machinery, but it has not yet been done.

FILIGRANE *work*, or filagree work, from *filum* and *granum*, is the name given to a kind of ornamental work, in which flowers, &c. are formed of fine gold and silver wire curled or twisted in a serpentine form, and sometimes plaited, and worked through each other, and soldered together. This art appears to have been brought from the East, and has been occasionally employed in all ages.

FILIX, an order of the cryptogamia class of plants, comprehending the fern, horse-tail, adder's-tongue, maiden-hair, spleen-wort, polypody, &c.

FILLET, in heraldry, a kind of bordure, containing only a third or fourth part of the breadth of the common bordure. It is supposed to be withdrawn inwards, and is of a different colour from the field.

FILTER, or *filtre*, in chemistry, a strainer commonly made of bibulous or filtering paper in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid.

FILTERING paper, is paper without size. To use it as such, the paper is shaped into the form of a cone, and placed in a funnel, in order to support it; otherwise it would break.

Filtering stones, basons, &c. are either natural or artificial, for the purpose of purifying water.

The common filtering stones are liable to several objections, such as their pores becoming closed up by the sediment which is deposited by the impure water, the inequality of the pressure, &c. Various filtering machines have been invented by different persons; but the simplest we have ever seen described, and which, on account of its cheapness, falls within the reach of every family, is one invented by Mr. Lewis of London, and by him described in the Mechanics Magazine. "It consists of a large earthen flower-pot, through the bottom of which is fixed a leaden pipe, of sufficient length to reach within six inches of the top of the pot. The bottom of the pot, (inside) is then covered with fine clean sand, about two inches deep; above this is another layer of coarser sand, mixed with charcoal dust, about two inches deep; and over all there is a layer of coarse sand, or gravel. Another pot, much smaller than the first, is then inverted over the pipe, inside the large pot, and pressed down through the sand, till it nearly touches the bottom: the machine is now complete

The water is poured into the sand and gravel around the exterior of the inverted pot. It filters to the bottom, then finds its way up the inside of the smaller pot, till it reaches the top of the leaden pipe, down which it immediately runs into any vessel put to receive it. As this filtering machine acts on the principle of a syphon, the water is drawn through much quicker than when it falls merely by its own weight.

This simple filtering machine will be found highly beneficial to those who value the luxury of pure soft water during the heat of summer. The editor has tried the experiment; and with one, on rather a small scale, but carefully constructed, he obtained the following result.

From a wooden rain-water cistern a quantity of water was taken, teeming with animalcula, and having a very offensive smell. It was then poured gently on the gravel in the machine, and began, in the course of ten minutes, to run from the pipe, at the rate of a pint in four minutes, having the appearance of the finest spring water, and so completely freed from every thing offensive, that on being presented at table it was pronounced to be excellent.

It is recommended to place a layer of fine pebbles over the surface of the gravel to prevent its being disturbed by the pouring on of the water.

FIN, in natural history, a well-known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles.

FINANCE, the œconomy of the public revenue and expenditure of nations.

The English system of finance rests on the produce of the various taxes which have been imposed at different periods, the aggregate amount of which, after deducting the expences of collection, together with a few small articles which cannot properly be called taxes, forms the whole of the public income. This income is annually appropriated to the several branches of the national expenditure, and when in consequence of any extraordinary expences it is known that the income of the current year will be insufficient to meet all the demands upon it, it is usual to borrow the sum necessary to make up the deficiency, either from individuals or public bodies, and to allow a fixed rate of interest on the money thus obtained, till the principal shall be repaid, or till the period originally agreed upon shall have expired.

FINE, in law, hath different significations. It sometimes denotes a formal conveyance of lands or tenements or of any inheritable thing in order to cut off all controversies: sometimes it means a sum of money paid for entering into the possession of lands or tenements let by lease. Again it signifies a pecuniary mulct for an offence committed against the king or the lord of the manor.

FINERS of gold and silver, are those who separate those metals from coarser ores.

FINERY, in the iron-works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar.

FIRE. See CALORIC and COMBUSTION.

FIRE, *balls of*, in meteorology, a kind of luminous bodies, generally appearing at a great height above the earth, with a splendour surpassing that of the moon; and sometimes equalling her apparent size. They generally proceed in this hemisphere from north to south with vast velocity, frequently breaking into several smaller ones, sometimes vanishing with a report, sometimes not.

FIRE-*ball*, in the art of war, a composition of meal-powder, sulphur, saltpetre, pitch, &c. about the size of a hand-grenade, coated over with flax, and primed with a slow composition of a fuse. This is to be thrown into the enemy's works in the night time, to discover where they are: or to fire houses, galleries, or blinds of the besiegers; but the use of these is now superseded by the still more certainly destructive invention of the Congreve Rocket.

FIRE-*ships*, in the navy, are vessels charged with combustible materials or artificial fireworks; which having the wind of an enemy's ship, grapple her, and set her on fire.

FIRE *flies*, a species of flies common in Guiana, of which there are two species. The largest is more than an inch in length, having a very large head connected with the body by a joint of a particular structure, with which sometimes it makes a loud knock, particularly when laid on its back. The fly has two feelers or horns, two wings, and six legs. Under its belly is a circular patch, which, in the dark, shines like a candle; and on each side of the head near the eyes is a prominent, globular, luminous body, in size about one-third larger than a mustard-seed. Each of these bodies is like a living star, emitting a bright, and not small, light; since two or three of these animals, put into a glass vessel, afford a light sufficient to read without difficulty, if placed close to the book. When the fly is dead, these bodies will still afford considerable light, though it is less vivid than before; and if bruised, and rubbed over the hands or face, they become luminous in the dark, like a board smeared over with English phosphorus. They are of a reddish-brown or chesnut colour: and live in rotten trees in the day, but are always abroad in the night. The other kind is not more than half as large as the former: their light proceeds from under their wings, and is seen only when they are elevated, like sparks of fire appearing or disappearing at every second.

FIRE *engine.* See HYDROSTATICS.

FIRKIN, an English measure of capacity, for things liquid, being the fourth part of the barrel: it contains nine gallons of beer.

FIRLOT, a dry measure used in Scotland. The oat-firlot contains 21¼ pints of that country; the wheat-firlot contains about 2,211 cubical inches; and the barley-firlot, 31 standard pints.

FIRST *fruits* and *tenths*, in law. First fruits are the profits of every spiritual living for one year: and tenths are the tenth of the yearly value of such living, given anciently to the Pope throughout all Christendom; but by stat. 26 Hen. VIII. c. 3. transferred to the King of England. By stat. 27 Hen VIII. c. 3. no tenths are to be paid for the first year, as then the first fruits are due; and by several statutes in the reign of Queen Anne, benefices under 50*l.* per annum shall be discharged of the payment of first fruits and tenths. She also restored the profits of this revenue to the church, by establishing a perpetual fund therefrom, vested in trustees for the augmentation of poor livings under 50*l.* a year. This is called Queen Anne's bounty, and is further regulated by subsequent statutes; but as the number of livings under 50*l.* was at the commencement of it 5,597, averaged at 23*l.* per annum, its operation will be very slow

FISCAL, in the civil law, something relating to the pecuniary interest of the prince or people.

FISH. See PISCES.

FISHERY, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring,

mackrel, pilchards, &c. are along the coasts of England, Scotland and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West Indies.

Free fishery, in law, or an exclusive right of fishing in a public river, is a royal franchise; and differs from a several of piscary, because he that has a several fishery must also be the owner of the soil, which in a free fishery is not requisite. It differs also from the common fishery, in that the free fishery is an exclusive right, the common is not so; and therefore, in a free fishery, a man has a property in the fish before they are caught; in a common pisca[illegible] not till afterwards.

FISTULA, in surgery, a deep, narrow and callous ulcer, generally arising from abscesses.

FISTULARIA, *pipe fish*, a genus of the order abdominales. The species are:

1. *Fistularia tabacaria*, or slender fistularia. This grows to the length of three or four feet, and is of the shape of an eel, the head about nine inches long; the eyes are large and ovate, with a blue pupil and silvery iris, marked on the fore and hind part by a red spot; the skin smooth and of a liver-colour marked by blue spots, with greenish ones intermixed. The appearance of the tail is singular, being deeply forked, while from the middle of the furcature springs a long bristle process, resembling whalebone, and tapering to a point. A variety has been observed by Dr. Bloch, in which this part was double, and the snout serrated on each side.

This species lives chiefly on the smaller fishes, sea-insects, and worms.

2. *Fistularia Chinensis*, or *Chinese Fistularia*, in its general shape resembles an eel, but the body is thicker in proportion than in the preceding species: It is a native of the Indian seas, preying on worms, sea-insects, &c.

3. *Fistularia paradoxa*, paradoxical fistularia, is a small species, from two to four inches in length. It is a native of the Indian seas.

FITCHEE, in heraldry, a term applied to a cross, when the lower end of it is sharpened into a point.

FIXED *stars*. See Astronomy.

FLACOURTIA, a genus of the class and order dioecia polyandria. There is one species, a small tree of Madagascar, bearing an eatable fruit in some degree resembling a plum.

FLAG, a general name for colours, standards, ancients, banners, ensigns, &c. which are frequently confounded with each other.

The fashion of pointed, or triangular flags, as now used, came from the Mahometan Arabs, or Saracens, upon their seizing of Spain, before which time all the ensigns of war were stretched, or extended on cross pieces of wood, like the banners of a church. The pirates of Algiers, and throughout the coasts of Barbary, bear an hexagonal flag.

Flag, is more particularly used at sea, for the colours, antients, standards, &c. borne on the top of the masts of vessels, to notify the person who commands the ship, of what nation it is, and whether it is equipped for war or trade.

The admiral in chief carries his flag on the mai[illegible]p; and the vice-admiral on the fore-top; and the rear-admiral on the mizen top.

FLAGELLARIA a genus of the hexandria monogynia class and order of plants. There are two species, shrubs of the East Indies.

FLAGEOLET, or *flajeolet*, a little flute, used chiefly by shepherds, and country people. It is made of box, or any other hard wood, and sometimes of ivory; and has six holes besides that at the bottom, the mouth-piece, and that behind the neck.

FLAIL, an instrument for thrashing corn. See Husbandry.

A flail consists of the following parts: 1. The hand-staff, or piece held in the thrasher's hand 2. The swiple, or that part which strikes out the corn. 3. The caplins, or strong double leathers, made fast to the tops of the hand-staff and swiple. 4. The middle-band, being the leather-thong, or fish-skin, that ties the caplins together.

FLAME. The following is the description given of flame by Mr. Gurney, in his Lectures on Chemical Science.

"The *flame* proceeding from a burning body is hollow within; that is, it contains within it no matter in actual combustion; and it assumes the conical form, which it usually bears, in consequence of the pressure of the external air on the outward side of it.

The flame, as it is called, consists of a thin *film* or *coat* of matter in a state of actual combustion, and this film is the only portion of the burning body which can properly be said to be in that state. I conceive that it assumes this appearance at the precise instant the combustible body and the supporter of combustion enter into combination with each other. Immediately on taking this form it passes off from the quantity of combustible matter which exists within it; and which matter itself proceeds immediately from the main body which is supplying the whole; so that an object in a state of flame, seems to consist of matter under three several states or forms: first, the main body of the object which is gradually passing from a low to a high temperature; secondly, that portion of the object in question which has already reached that high temperature, but has not yet passed into a state of flame, because it is confined within the external film of flame, and is therefore not capable of coming into contact with the atmosphere that is to supply it with oxygen or support; and lastly, that portion which is in a state of actual flame, and is passing off from time to time, thus permitting another portion of that contained within it to assume a similar form.

FLAMINGO, in ornithology. See Phœnicopterus.

FLANKS *of an army*, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

Flanks *of a bastion*, in fortification, that part which joins the face to the curtain. See Fortification.

FLANNEL, a kind of slight, loose, woollen stuff, composed of a woof and warp, and woven on a loom with two treadles, after the manner of baize. Dr. Black assigns as a reason why flannel and other substances of the kind keep our bodies warm, that they compose a rare and spongy mass, the fibres of which touch each other so slightly, that the heat moves slowly through the interstices, which being filled only with air, and that in a stagnant state, gives little assistance in conducting the heat.

FLAT, in the sea-language. To flat in the fore-sail, to hale it in by the sheet, as near the ship's side as possible: which is done when a ship will not fall off from the wind.

Flat, in music, a character which being placed before a note, signifies that the note is to be sung or played half a tone lower than its natural pitch.

FLATULENCY. See Medicine.

FLAX. See Linum.

FLEA. See Pulex.

FLEECE, the covering of wool, shorn off the bodies of sheep. See Wool.

FLEECY-*hosiery*, a useful kind of manufacture, in which fine fleeces of wool are interwoven into a cotton piece of the common stocking texture.

FLEET, commonly implies a company of ships of war, belonging to any prince or state; but sometimes it denotes any number of trading-ships, employed in a particular branch of commerce.

Fleet, a prison in London, to which persons are committed for contempt of the king and his laws, particularly of his courts of justice: or for debt, where any person will not, or is unable to pay his creditors. There are large rules, and a warden belonging to the Fleet prison, which had its name from the float or fleet of the river or ditch on the side whereof it stands.

FLESH, in anatomy, a fibrous part of an animal body, soft and bloody, being that of which most of the other parts are composed, and by which they are connected together: or, more properly, it is that part of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

FLEXOR. See Anatomy.

FLEXURE *of curves*, in the higher geometry, is used to signify that a curve is both concave and convex, with respect to a given right line.

FLINT, a semi transparent and hard stone, well known for its valuable property of giving fire when struck with steel. The colour is generally grey, with occasionally zoned and striped delineations. It occurs often in extraneous shapes, as echinites, coralites, madreporites, fungites, belemnites, mytilites, &c.; sometimes in lamellar concretions. Internal lustre glimmering. Fracture conchoidal. Fragments sharp-edged. Translucent. Harder than quartz. Easily frangible. Specific gravity 2.59. Infusible without addition, but whitens and becomes opaque. Its constituents are 98 silica. 0.50 lime, 0.25 alumina, 0.25 oxide of iron, 1 0 loss. When two pieces of flint are rubbed together in the dark, they phosphoresce, and emit a peculiar smell.

It occurs in primitive transition, secondary and alluvial mountains. In the first two, in metalliferous and agate veins. In secondary countries it is found in pudding-stone, limestone, chalk, and amygdaloid. In chalk it occurs in great abundance in beds. These seem to have been both formed at the same time. Werner, however, is of opinion, that the tube rose and many other forms, have been produced by infiltration. In Scotland, it occurs imbedded in secondary limestone in the island of Mull, and near Kirkaldy in Fifeshire. In England, it abounds in alluvial districts in the form of gravel, or is imbedded in chalk. In Ireland it occurs in considerable quantities in secondary limestone. It is found in most parts of the world

The manufacture of gun-flints is chiefly confined to England, and two or three departments of France. The operation is exceedingly simple, and a good workman will make 1000 flints a day. The whole art consists in striking the stone repeatedly with a kind of mallet, and bringing off at each stroke a splinter, sharp at one end, and thicker at the other. The splinters are afterwards shaped at pleasure, by laying the line at which it is wished they should break, upon a sharp instrument, and then giving [illegible] small blows with a mallet.

FLOAT *of a fishing line*, the cork or quill that floats or swims above the water.

Float also signifies a certain quantity of timber bound together with rafters athwart, and put into a river to be conveyed down the stream; and even sometimes to carry burdens down a river with the stream.

Float-*boards*, those boards fixed to water-wheels of undershot mills, serving to receive the impulse of the stream, whereby the wheel is carried round.

FLOOD, among seamen, is when the tide begins to come up, or the water begins to rise• then they call it young flood; after which it is quarter-flood, half-flood, and high-flood.

FLORIN, is sometimes used for a coin, and sometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding thirteen or fourteen carats, and none of them seventeen and a half. As to silver florins, those of Holland are worth about 1*s*. 8*d*.

FLOS, in chemistry, the most subtile part of bodies, separated from the more gross parts by sublimation, in a dry form.

FLOUR, the meal of wheat corn, finely ground and sifted. Flour, when carefully analyzed, is found to be composed, 1. of fecula, which is insoluble in cold water, but soluble in hot water; 2. of gluten; 3. of a saccharine matter, susceptible of the spirituous fermentation

FLOWER, *flos*, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification. See Botany.

Flowers, *preserving of*. The method of preserving flowers in their natural beauty through the whole year has been much sought after. Some have attempted it by gathering them when dry, and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, takes off from the liveliness of their colour. Muntingius prefers the following method to all others. Gather roses, or other flowers, when they are not yet thoroughly open, in the middle of a dry day: put them into a good earthen vessel glazed within; fill the vessel up to the top with them; and when full, sprinkle them over with some good French wine, with a little salt in it; then set them up in a cellar, tying down the mouth of the pot. After this they may be taken out at pleasure; and on setting them in the sun, or within reach of the fire, they will op[illegible] if growing naturally; and not only the colour, but the odour also, will be preserved.

and also g [illegible] one pound; armenian bole, two pounds; clean common sand, three pounds. Mix all well together; then gather fruit of any kind that is not fully ripe, with the stalk to each; put these, one by one, into a wide-mouthed glass, laying them in good order. Tie over the top with an oil-cloth, and carry them into a dry cellar, and set the whole upon a bed of the prepared matter of four inches thick in a box. Fill up the remainder of the box with the same preparation; and let it be four inches thick all over the top of the glass, and all round its sides. Flowers are to be preserved in the same sort of glasses, and in the same manner; and they may be taken up after a whole year as plump and fair as when they were buried.

Flower de lis, or *Flower de luce*, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty.

FLUATS, in chemistry, salts first discovered by Scheele; they are distinguished by the following properties: (1.) When sulphuric acid is poured upon them, they emit acrid vapours of fluoric acid, which corrode glass. (2.) When heated, several of them phosphoresce. (3.) They are not decomposed by heat, nor altered by combustibles. (4.) They combine with silica by means of heat. Most of them are sparingly soluble in water.

FLUID, in physiology, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed.

FLUIDITY. The state of bodies when their parts are very readily moveable in all directions with respect to each other.

Before Dr. Black began to deliver his chemical lectures in Glasgow in 1757, it was universally supposed that solids were converted into liquids by a small addition of heat, after they had been once raised to the melting point, and, that they returned again to the solid state on a very small diminution of the quantity of heat necessary to keep them at that temperature. An attentive view of the phenomena of liquefaction and solidification gradually led this philosopher to observe their inconsistence with the then received opinions, and to form another, which he verified by direct experiments, and drew up an account of his theory, and the proofs of it.

The opinion which he formed was, that when a solid body is converted into a liquid, a much greater quantity of heat enters into it than is perceptible immediately after by the thermometer. This great quantity of heat does not make the body apparently warmer, but it must be thrown into it in order to convert it into a liquid; and this great addition of heat is the principal and most immediate cause of the fluidity induced. On the other hand, when a liquid body assumes the form of a solid, a very great quantity of heat leaves it without sensibly diminishing its temperature; and the state of solidity cannot be induced without the abstraction of this great quantity of heat. Or, in other words, whenever a solid is converted into a fluid, it combines with a certain dose of caloric, without any augmentation of its temperature; and it is this dose of caloric which occasions the change of the solid into a fluid. When the [illegible] occasions the change. Thus the combination of a certain dose of caloric with ice causes it to become water, and the abstraction of a certain dose of caloric from water causes it to become ice. Water then is a compound of ice and caloric; and in general all fluids are combinations of the solid, to which they may be converted by the application of cold, and a certain dose of caloric.

FLUOR *spar*, the native fluate of lime.

FLUORIC *acid*. The fusible spar, which is generally distinguished by the name of Derbyshire spar, consists of calcareous earth in combination with the acid at present under our consideration. If the pure fluor, or spar, be placed in a retort of lead or silver, with a receiver of the same metal adapted, and its weight of sulphuric acid be then poured upon it, the fluoric acid will be disengaged by the application of a moderate heat. This acid gas readily combines with water; for which purpose it is necessary that the receiver should previously be half filled with that fluid.

If the receiver be cooled with ice, and no water put in it, then the condensed acid is an intensely active liquid, first procured by M. Gay Lussac. The best account of it, however, has been given by Sir H. Davy. It has the appearance of sulphuric acid, but is much more volatile, and sends off white fumes when exposed to air. Its specific gravity is only 1.0609. It must be examined with great caution; for when applied to the skin it instantly disorganizes it, and produces very painful wounds. When potassium is introduced into it, it acts with intense energy, and produces hydrogen gas and a neutral salt; when lime is made to act upon it, there is a violent heat excited, water is formed, and the same substance as fluor spar is produced. With water in a certain proportion, its density increases to 1.25. When it is dropped into water, a hissing noise is produced with much heat, and an acid fluid not disagreeable to the taste is formed if the water be in sufficient quantity. It instantly corrodes and dissolves glass.

It appears extremely probable, from all the facts known respecting the fluoric combinations, that fluor spar contains a peculiar acid matter; and that this acid matter is united to lime in the spar, seems evident from the circumstance, that gypsum or sulphate of lime is the residuum of the distillation of fluor spar and sulphuric acid.

From the remarkable property fluoric acid possesses of corroding glass, it has been employed for etching on it, both in the gaseous state and combined with water. See Engraving.

FLUSTRA, a genus of insects of the order zoophyta; an animal of the polypus kind, proceeding from porous shells: stem fixed, foliaceous, membranaceous, consisting of numerous rows of cells united together, and woven like a mat. There are many species.

FLUTE, *fistula*, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side. The ancient fistulæ, or flutes.

were made of reeds, afterwards of wood, and of metal; but how they were blown, whether as our flutes, or as hautboys, does not appear.

Flute, *German*, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is stopped with a tampion, or plug, and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long, rather larger at the upper end than the lower, and perforated with holes, besides that for the mouth, the lowest of which is stopped and opened by the little finger's pressing on a brass, or sometimes a silver key, but the modern flutes have often six or sometimes more keys.

FLUTES, or *flutings*, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. See Architecture.

FLUX. A general term made use of to denote any substance or mixture added to assist the fusion of minerals. In the large way, limestone and fusible spar are used as fluxes. The fluxes made use of in assays, or philosophical experiments, consist usually of alkalis, which render the earthy mixtures fusible, by converting them into glass; or else glass itself in powder.

Alkaline fluxes are either the crude flux, the white flux, or the black flux. Crude flux is a mixture of nitre and tartar, which is put into the crucible with the mineral intended to be fused. The detonation of the nitre with the inflammable matter of the tartar, is of service in some operations; though generally it is attended with inconvenience on account of the swelling of the materials, which may throw them out of the vessel, if proper care be not taken either to throw in only a little of the mixture at a time, or to provide a large vessel.

White flux is formed by projecting equal parts of a mixture of nitre and tartar, by moderate portions at a time, into an ignited crucible. In the detonation which ensues, the nitric acid is decomposed, and flies off with the tartaric acid, and the remainder consists of the potash in a state of considerable purity. This has been called fixed nitre.

Black flux differs from the preceding, in the proportion of its ingredients. In this, the weight of the tartar is double that of the nitre; on which account the combustion is incomplete, and a considerable portion of the tartaric acid is decomposed by the mere heat, and leaves a quantity of coal behind, on which the black colour depends. It is used where metallic ores are intended to be reduced, and effects this purpose, by combining with the oxygen of the oxide.

The advantage of M. Morveau's reducing flux, seems to depend on its containing no excess of alkali. It is made of eight parts of pulverized glass, one of calcined borax, and half a part of powder of charcoal. Care must be taken to use a glass which contains no lead. The white glasses contain in general a large proportion, and the green bottle glasses are not perhaps entirely free from it.

FLUXION, in mathematics, denotes the velocity by which the fluents or flowing quantities increase or decrease; and may be considered as positive or negative, according as it relates to an increment or decrement.

The doctrine of fluxions, first invented by Sir Isaac Newton, is of great use in the investigation of curves, and in the discovery of the quadratures of curvilinear spaces, and their rectifications. In this method, magnitudes are conceived to be generated by motion, and the velocity of the generating motion is the fluxion of the magnitude. Thus, the velocity of the point that describes a line, is its fluxion, and measures its increase or decrease. When the motion of this point is uniform, its fluxion or velocity is constant, and may be measured by the space described in a given time, but when the motion varies, the fluxion of velocity at any given point is measured by the space that would be described in a given time, if the motion was to be continued uniformly from that term.

Thus, let the point m be conceived to move from A, and generate the variable right line Am, by a motion any how regulated; and let its velocity, when it arrives at any proposed position or point R, be such as would, were it to continue uniform from that point, be sufficient to describe the line Rr, in the given time allotted for the fluxion, then will Rr be the fluxion of the variable line Am, in the term or point R.

The fluxion of a plain surface is conceived in like manner, by supposing a given right line mn (Plate XVI. fig. 1.) to move parallel to itself, in the plane of the parallel and moveable lines AF and BG: for if, as above, Rr be taken to express the fluxion of the line Am, and the rectangle RrsS be completed; then that rectangle, being the space which would be uniformly described by the generating line mn, in the time that Am would be uniformly increased by mr, is therefore the fluxion of the generated rectangle Bm, in that position.

If the length of the generating line mn continually varies, the fluxion of the area will still be expounded by a rectangle under that line, and the fluxion of the absciss or base: for let the curvilinear space Anm (fig. 2) be generated by the continual and parallel motion of the variable line mn: and let Rr be the fluxion of the base or absciss Am, as before, then the rectangle RrsS, will be the fluxion of the generated space Amn. Because, if the length and velocity of the generating line mn were to continue invariable from the position RS, the rectangle RrsS would then be uniformly generated with the very velocity wherewith it begins to be generated, or with which the space Amn is increased in that position.

FLUXIONS, *notation of*, of invariable quantities, or those which neither increase nor decrease, are represented by the first letters of the alphabet, as a, b, c, d, &c. and the variable or flowing quantities by the last letters, as, v, w, x, y, z: thus, the diameter of a given circle may be denoted by a; and the sine of any arc thereof, considered as variable, by x. The fluxion of a quantity represented by a single letter, is expressed by the same letter with a dot or full point over it: thus, the fluxion of x is represented by $\dot{x}$, and that of y by $\dot{y}$. And, because these fluxions are themselves often variable quantities, the velocities with which they either increase or decrease, are the fluxions of the former fluxions, which may be called

second fluxions, and are denoted by the same letters with two dots over them, and so on to the third, fourth, &c. fluxions. The whole doctrine of fluxions consists in solving the two following problems, *viz* From the fluent, or variable flowing quantity given, to find the fluxion; which constitutes what is called the direct method of fluxions. 2. From the fluxion given, to find the fluent, or flowing quantity; which makes the inverse method of fluxions.

Fluxions, *direct method of*, the doctrine of this part of fluxions is comprised in these rules.

1. To find the fluxion of any simple variable quantity, the rule is to place a dot over it: thus, the fluxion of x is $\dot{x}$, and of y, $\dot{y}$. Again, the fluxion of the compound quantity $x+y$, is $\dot{x}+\dot{y}$: also the fluxion of $x-y$, is $\dot{x}-\dot{y}$.

2. To find the fluxion of any given power of a variable quantity, multiply the fluxion of the root by the exponent of the power, and the product by that power of the same root, whose exponent is less by unity than the given exponent. This rule is expresed more briefly, in algebraical characters, by $nx^{n-1}\dot{x}=$ the fluxion of x^n. Thus the fluxion of x^3 is $\dot{x}\times3\times x^2=3x\dot{x}$; and the fluxion of x^5 is $\dot{x}\times5\times x^4=5x^4\dot{x}$.

3. To find the fluxion of the product of several variable quantities, multiply the fluxion of each, by the product of the rest of the quantities; and the sum of the products, thus arising will be the fluxion sought. Thus, the fluxion of xy is $x\dot{y}+y\dot{x}$; that of xyz, is $\dot{x}yz+\dot{y}xz+\dot{z}xy$; and that of $vxyz$ is $vxyz+\dot{x}vyz+\dot{y}vxz+\dot{z}vxz$. Again the fluxion of $\overline{a+x}\times\overline{b-y}=ab+bx-ay-xy$, is $b\dot{x}-a\dot{y}-\dot{x}y-\dot{y}x$.

4. To find the fluxion of a fraction, the rule is, from the fluxion of the numerator, multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator. Thus, the fluxion of $\frac{x}{y}$, is $\frac{y\dot{x}-x\dot{y}}{y^2}$; that of $\frac{x}{x+y}$, is $\frac{\dot{x}\times\overline{x+y}-\overline{\dot{x}+\dot{y}}\times x}{\overline{x+y}|^2}=\frac{y\dot{x}-x\dot{y}}{\overline{x+y}|^2}$; and that of $\frac{x+y+z}{x+y}$, or $1+\frac{z}{x+y}$, is $\frac{\dot{z}\times\overline{x+y}-\overline{\dot{x}+\dot{y}}\times z}{\overline{x+y}|^2}$; and so of others.

In the examples hitherto given, each is resolved by its own particular rule: but in those that follow, the use of two or more of the above rules is requisite; thus (by rule 2 and 3) the fluxion of x^2y^2 is found to be $2x^2y\dot{y}+2y^2x\dot{x}$; that of $\frac{x^2}{y^2}$, is found (by rule 2 and 4) to be $\frac{2y^2x\dot{x}-2x^2y\dot{y}}{y^4}$; and that of $\frac{x^2y^2}{z}$, is (by rule 2, 3, and 4,) found to be $\frac{\overline{2x^2y\dot{y}+2y^2x\dot{x}}\times z-x^2y^2\dot{z}}{z^2}$.

5. When the proposed quantity is affected by a coefficient, or constant multiplicator, the fluxion found as above must be multiplied by that coefficient or multiplicator: thus, the fluxion of $5x^3$, is $15x^2\dot{x}$; for the fluxion of x^3 is $3x^2\dot{x}$, which, multiplied by 5, gives $15x^2\dot{x}$. And, in the very same manner, the fluxion of ax^n will be $nax^{n-1}\dot{x}$.

Having explained the manner of determining the first fluxions of variable quantities, it is unnecessary in a work of this kind to enter upon the second, third, &c. fluxions. We shall therefore proceed to

Fluxions, *inverse method of*, or the manner of determining the fluents of given fluxions.

If what is already delivered, concerning the direct method, be duly considered, there will be no great difficulty in conceiving the reasons of the inverse method: though the difficulties that occur in this last part, upon another account, are indeed vastly great. It is an easy matter, or not impossible at most, to find the fluxion of any flowing quantity whatever; but, in the inverse method, the case is quite otherwise; for, as there is no method for deducing the fluent from the fluxion *a priori*, by a direct investigation; so it is impossible to lay down rules for any other forms of fluxions, than those particular ones, that we know, from the direct method, belong to such and such kinds of flowing quantities; thus, for example, the fluent of $2x\dot{x}$ is known to be x^2; because, by the direct method, the fluxion of x^2 is found to be $2x\dot{x}$: but the fluent of $y\dot{x}$ is unknown, since no expression has been discovered that produces $y\dot{x}$ for its fluxion. Be this as it will, the following rules are those used by the best mathematicians, for finding the fluents of given fluxions.

1. To find the fluent of any simple fluxion, you need only write the letters without the dots over them: thus the fluent of $\dot{x}$ is x, and that of $a\dot{x}+b\dot{y}$, is $ax+by$.

2. To assign the fluent any power of a variable quantity, multiplied by the fluxion of the root; first divide by the fluxion of the root; add unity to the exponent of the power, and divide by the exponent so increased; for, dividing the fluxion $nx^{n-1}\dot{x}$ by $\dot{x}$, it becomes nx^{n-1}; and adding 1 to the exponent $(n-1)$ we have nx^n; which, divided by n, gives x^n, the true fluent of $nx^{n-1}\dot{x}$. Hence, by the same rule, the fluent of $3x^2\dot{x}$ will be $=x^3$; that of $2x^5\dot{x}=\frac{x^6}{3}$; that of $y^{\frac{1}{2}}\dot{y}=\frac{2}{3}y^{\frac{3}{2}}$; that of $ay^{\frac{5}{3}}\dot{y}=\frac{3ay}{8}$; and that of $y^{\frac{m}{n}}\dot{y}=\frac{y^{\frac{m}{n}+1}}{\frac{m}{n}+1}=\frac{ny^{\frac{m+n}{n}}}{m+n}$; that of $\frac{a\dot{x}}{nx}$, or $a\dot{x}x^{-n}=\frac{ax^{1-n}}{1-n}$; that of $\overline{a+z}|^3\times\dot{z}=\frac{\overline{a+z}|^4}{4}$; and that of $\overline{a+z^m}|^n\times z^{m-1}\dot{z}=\frac{\overline{a+z^m}|^{n+1}}{m\times\overline{n\times1}|}$.

In assigning the fluents of given fluxions, it ought to be considered, whether the flowing quantity found as above, requires the addition or subtraction of some constant quantity, to render it complete: thus, for instance, the fluent of $nx^{n-1}\dot{x}$ may be either represented by x^n or by $x^n \pm a$; for a being a constant quantity, the fluxion of $x^n \pm a$, as well as of x^n, is $nx^{n-1}\dot{x}$.

Hence it appears, that the variable part of a fluent only can be assigned by the common method, the constant part being only assignable from the particular nature of the problem. Now to do this, the best way is to consider how much the variable part of the fluent first found, differs from the truth, when the quantity which the whole fluent ought to express is equal to nothing; then that difference, added to, or subtracted from, the said variable part, as occasion requires, will give the fluent truly corrected. To make this plainer by an example or two, let $\dot{y} = \overline{a+x}|^3 \times \dot{x}$. Here we first find $y = \frac{\overline{a+x}|^4}{4}$; but when $y = 0$, then $\frac{\overline{a+x}|^4}{4}$ becomes $= \frac{a^4}{4}$; since x, by hypothesis, is then $=0$: therefore $\frac{\overline{a+x}|^4}{4}$ always exceeds y by $\frac{a^4}{4}$; and so the fluent, properly corrected, will be $y = \frac{\overline{a+x}|^4 - a^4}{4} = a^3x + \frac{3a^2x^2}{2} + ax^3 + \frac{x^4}{4}$. Again, let $\dot{y} = \overline{a^m + x^m}|^n \times x^{m-1}\dot{x}$; here we first have $y = \frac{\overline{a^m + x^m}|^{n+1}}{m \times \overline{n+1}}$; and making $y=0$, the latter part of the equation becomes $\frac{\overline{a^m}|^{n+1}}{m \times \overline{n+1}} = \frac{a^{mn+m}}{m \times \overline{n+1}}$; whence the equation or fluent, properly corrected, is $y = \frac{\overline{a^m + x^m}|^{n+1} - a^{mn+m}}{m \times \overline{n+1}}$. Hitherto x and y are both supposed equal to nothing, at the same time; which will not always be the case: thus, for instance, though the sine and tangent of an arch are both equal to nothing, when the arch itself is so; yet the secant is then equal to the radius. It will therefore be proper to add some examples, in which the value of y is equal to nothing, when that of x is equal to any given quantity a. Thus, let the equation $\dot{y} = x^2\dot{x}$ be proposed; whereof the fluent first found is $y = \frac{x^3}{3}$; but when $y=0$, then $\frac{x^3}{3} = \frac{a^3}{3}$, by the hypothesis; therefore the fluent, corrected, is $y = \frac{x^3 - a^3}{3}$.

Again, suppose $\dot{y} = x^n\dot{x}$, then will $y = \frac{x^{n+1}}{n+1}$, which, corrected, becomes $y = \frac{a^{n+1} - x^{n+1}}{n+1}$. And, lastly, if $\dot{y} = \overline{c^3 + bx^2}|^{\frac{1}{2}} \times x\dot{x}$; then first, $y = \frac{\overline{c^3 + bx^2}|^{\frac{3}{2}}}{3b}$; therefore, the fluent corrected, is $y = \frac{\overline{c^3 + bx^2}|^{\frac{3}{2}} - \overline{c^3 + ba^2}|^{\frac{3}{2}}}{3b}$.

3. To find the fluents of such fluxionary expressions as involve two or more variable quantities, substitute, instead of such fluxion, its respective flowing quantity; and, adding all the terms together, divide the sum by the number of terms, and the qnotient will be the fluent. Thus, the fluent of $\dot{x}y + \dot{y}x = \frac{xy+xy}{2} = \frac{2xy}{2} = xy$: and the fluent of $\dot{x}yz + \dot{y}xz + \dot{z}yx = \frac{xyz + xyz + xyz}{3} = \frac{3xyz}{3} = xyz$. But it seldom happens that these kinds of fluxions, which involve two variable quantities in one term, and yet admit of known and perfect fluents, are to be met with in practice.

Having thus shewn the manner of finding such fluents as can be truly exhibited in algebraic terms, it remains now to say something with regard to those other forms of expressions involving one variable quantity only: which yet are so affected by compound divisors and radical quantities, that their fluents cannot be accurately determined by any method whatsoever. The only method with regard to these, of which there are innumerable kinds, is to find their fluents by approximation, which, by the method of infinite series, may be done to any degree of exactness.

Thus, if it were proposed to find the fluent of $\frac{a\dot{x}}{a-x}$, it becomes necessary to throw the fluxion into an infinite series, by dividing $a\dot{x}$ by $a-x$: thus, $a\dot{x} \div \overline{a-x} = \dot{x} + \frac{x\dot{x}}{a} + \frac{x^2\dot{x}}{a^2} + \frac{x^3\dot{x}}{a^3} + \frac{x^4\dot{x}}{a^4} +$, &c. Now the fluent of each term of this series, may be found by the foregoing rules to be $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3} + \frac{x^5}{5a^4} +$, &c.

In order to shew the usefulness of fluxions, we shall give an example or two. 1. Suppose it were required to divide any given right line AB into two such parts, AC, CB, that their products are rectangles, may be the greatest possible. Let A B $=a$, and let the part A C, considered as variable (by the motion of C towards B) be denoted by x. Then B C being $=a-x$, we have A C × B C $= ax - xx$, whose fluxion $a\dot{x} - 2x\dot{x}$ being put $=0$, we get $a\dot{x} = 2x\dot{x}$: and, consequently, $x = \frac{1}{2}a$. Hence it appears that A C (or x) must be exactly one half of A B.

Ex. 2. To inscribe the greatest parallelo-

gram $DFGI$ in a given triangle ABC, fig. 3.

Draw BH perpendicular to AC; put $AC=a$, $BH=b$, $BE=x$, then $EH=b-x$: and by similar triangles, $b:a::x:DF=\frac{ax}{b}$; hence, the area $DFGI=\frac{ax}{b}\times\overline{b-x}=$ max. or $x\times\overline{b-x}=bx-x^2=$ max. ∴ $b\dot{x}-2x\dot{x}=0$; hence, $x=\frac{1}{2}b$; therefore $EH=\frac{1}{2}BH$.

Ex. 3. Let ABC represent a cone, AC the diameter of the base; to inscribe in it the greatest cylinder $DFGI$, fig. 4.

Put $p=,78539$, &c. then since $AC=a$. $BH=b$. $BE=x\frac{pa^2x^2}{b^2}=$ the area of the end DEF of the cylinder; hence, the content of the cylinder $=\frac{pa^2x^2}{b^2}\times\overline{b-x}=$ max. or $x^2\times\overline{b-x}=bx^2-x^3=$ max. . . $2bx\dot{x}-3x^2\dot{x}=0$; hence, $x=\frac{2}{3}b$· therefore $EH=\frac{1}{3}BH$. See Cylinder.

Ex. 4. To inscribe the greatest parallelogram $DFGI$ in a given parabola ABC, fig. 5.

Put $BH=a$, $p=$ the parameter, $x=BE$; then by the property of the parabola, $DE^2=px$, ∴ $DE=p^{\frac{1}{2}}x^{\frac{1}{2}}$, and $DF=2p^{\frac{1}{2}}x^{\frac{1}{2}}$; hence, the area $DFGI=2p^{\frac{1}{2}}x^{\frac{1}{2}}\times\overline{a-x}=$ max. or $x^{\frac{1}{2}}\times\overline{a-x}=ax^{\frac{1}{2}}-x^{\frac{3}{2}}=$ max. ∴ $ax^{-\frac{1}{2}}\dot{x}-\frac{3}{2}x^{\frac{1}{2}}\dot{x}=0$; hence, $\frac{a}{x^{\frac{1}{2}}}=3x^{\frac{1}{2}}$, or $a=3x$, ∴ $=\frac{1}{3}a$: consequently $EH=\frac{2}{3}BH$.

Ex. 5. To cut the greatest parabola DEF from a given cone ABC, fig. 6.

Let AGC be that of the diameter of the base which is perpendicular to DGF; now EG is parallel to AB; put $AC=a$, $AB=b$, $CG=x$, then $AG=a-x$: and by the property of the circle $DG=\sqrt{ax-x^2}$, ∴ $DF=2\sqrt{ax-x^2}$; also, by sim. △s, $a:b::x:GE=\frac{bx}{a}$; hence, we have the area of the parabola $=\frac{2}{3}\times\frac{bx}{a}\times2\sqrt{ax-x^2}=$ max. hence, $x\sqrt{ax-x^2}=$ max. or $x^2\times\overline{ax-x^2}=ax^3-x^4=$ max. ∴ $3ax^2\dot{x}-4x^3\dot{x}=0$, and $3a=4x$, ∴ $x=\frac{3}{4}a$.

FLY, in zoology. See Musca.

Fly, in mechanics, a cross with leaden weight at its ends, or rather a heavy wheel at right angles to the axis of a windlass, jack, &c.; by means of which the force of the power, whatever it may be, is not only preserved, but equally distributed in all parts of the revolution of the machine.

FLYERS, in architecture, such stairs as go straight, and do not wind round.

FLYING, the progressive motion of a bird, or other winged animal, in the liquid air. The parts of birds chiefly concerned in flying, are the wings, by which they are sustained or wafted along.

The manner of flying is thus: The bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers in them, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those successions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is produced. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer.

Flying *pinion*, is part of a clock, having a fly, or fan, to gather air, and check the rapidity of the clock's motion, when the weight descends in the striking part.

FOCUS, in geometry and conic sections, is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves concur.

FOCI *of an ellipsis*, are two points in the longest axis, on which as centres the figure is described.

Focus *of an hyperbola*, is that point in the axis, through which the latus rectum passes; from whence if any two right lines are drawn meeting in either of the opposite hyperbolas, their difference will be equal to the principal axis.

Focus *of a parabola*, a point in the axis within the figure, distant from the vertex one fourth part of the latus rectum.

Focus, in optics, is the point in which the rays are collected, after they have undergone reflection or refraction.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

Fodder, or *Fother*, in mining, a measure containing twenty-two hundred and a half-weight, though in London but twenty hundred weight.

FOG, or *Mist*, a meteor, consisting of condensed vapours, floating near the surface of the earth. If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous heat, at their first entrance into the atmosphere meet with cold enough to condense them to a considerable degree, their specific gravity is by that means increased, and thus they will be stopped from ascending; and either return back in form of dew or of drizzling rain, or remain suspended in the form of a fog. See Meteorology.

FOIL, among glass-grinders, a sheet of tin, with quicksilver, &c. laid on the backside of a looking-glass, to make it reflect.

Foil, among jewellers, a thin leaf of metal placed under a precious stone, in order to increase its brilliancy, or give it an agreeable and different colour.

FOLIATING *of looking-glasses*, the spreading the plates over, after they are polished, with amalgam, in order to reflect the image. It is performed thus: a thin blotting paper is spread on the table, and sprinkled with fine chalk; and then a fine lamina or leaf of tin called foil, is laid over the paper; upon this mercury is poured, which is to be distributed equally over the leaf with a hare's-foot, or cotton: over this is laid a clean paper, and

over that the glass plate, which is pressed down with the right-hand, and the paper drawn gently out with the left; this being done, the plate is covered with a thicker paper, and loaded with a greater weight, that the superfluous mercury may be driven out, and the tin adhere more closely to the glass. When it is dried, the weight is removed, and the looking glass is complete. Some add an ounce of marcasite, melted by the fire; and, lest the mercury should evaporate in smoke, pour it into cold water; and when cooled, squeeze it through a cloth or through leather.

Foliating *of globe looking-glasses*, is done as follows: Take five ounces of quicksilver, and one ounce of bismuth; of lead and tin half an ounce each; first put the lead and tin into fusion, then put in the bismuth, and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quicksilver into it; after this, take the glass globe, which must be very clean, and the inside free from dust; make a paper funnel, which put into the hole of the globe, as near to the glass as you can, so that the amalgam when you pour it in may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where.

FONTANESIA, a genus of the diandria monogynia class and order. There is one species, an herb of Syria.

FONTINALIS, water-moss, a genus of the natural order of musci, in the cryptogamia class of plants. There are six species, all of them natives of Britain. They grow on the brinks of rivulets, and on the trunks of trees. The most remarkable is the antipyretica, with purple stalks.

FOOD. See Materia Medica.

FOOT, a part of the body of most animals whereon they stand, walk, &c.

Animals are distinguished with respect to the number of their feet, into bipedes, two-footed: such are men and birds; quadrupeds, four-footed; such are most land-animals: and multipedes, or many-footed, as insects.

Foot, in the Latin and Greek poetry, a metre or measure composed of a certain number of long and short syllables. These feet are commonly reckoned twenty-eight, of which some are simple, as consisting of two or three syllables, and therefore called disyllabic or trisyllabic feet; others are compound, consisting of four syllables, and are therefore called tetrasyllabic feet.

Foot is also a long measure, consisting of twelve inches. Geometricians divide the foot into ten digits, and the digits into ten lines.

Foot, *square*, is the same measure both in breadth and length, containing 144 square or superficial inches.

Foot, *cubic*, or *solid*, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches. The foot is of different lengths in different countries. The Paris royal foot exceeds the English by nine lines; the ancient Roman foot of the capitol, consisted of 4 palms, equal to $11\frac{7}{10}$ inches English; Rhineland or Leyden foot, by which the northern nations go, is to the Roman foot as 950 to 1000.

FORAGE, in military affairs, implies hay, straw, and oats, for the subsistence of the army horses.

FORCE, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform, or not direct.

FORCEPS, in surgery, &c. a pair of scissars for cutting off, or dividing, the fleshy membranous parts of the body, as occasion requires.

FORCER, or *forcing-pump*, in mechanics, is a kind of pump in which there is a forcer or piston without a valve. See Hydraulics.

FORCING, among gardeners, signifies the making trees produce ripe fruit before their usual time. This is done by planting them in a hot-bed against a south-wall, and likewise defending them from the injuries of the weather by a glass-frame. They should always be grown trees, as young ones are apt to be destroyed by this management.

FORE-*castle*, *of a ship*, that part where the foremost stands. It is divided from the rest by a bulk-head. See Ship.

Fore-*closed*, in law, signifies the being shut out, and excluded or barred, the equity of redemption on mortgages, &c.

FOREIGN *seamen*, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural born subjects.

FORLORN-*hope*, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle, or at a siege, to storm the counterscarp, mount the breach, &c.

FOREMAST of a ship, that which carries the fore-sail and fore-top sail yards.

Foremast-*men*, are those on board a ship that take in the top-sails, sling the yards, furl the sails, and take their turn at the helm, &c.

FORESTALLING, is the buying or bargaining for any corn, cattle, or other merchandize, by the way, before it comes to any market or fair, to be sold; or by the way, as it comes from beyond the seas, or otherwise, towards any city, port, haven, or creek of this realm, to the intent to sell the same again at a higher price.

FORESTER, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest at all hours, watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

Forests, are waste grounds belonging to the king, replenished with all manner of beasts of chace on venery, which are under the king's protection, for the sake of his royal recreation; and there are particular laws, privileges, courts and officers belonging to the king's forests.

FORFEITURE, is a punishment annexed by law, to some illegal act or negligence in the owner of lands, tenements, or hereditaments, whereby he loses all his interest therein, and they go to the party injured, as a recompence for the wrong which either he alone or the public together with him have sustained.

FORFICULA, *earwig*, an insect of the coleoptera order. The wings of this insect are remarkably elegant, and are convoluted beneath their small sheaths in so curious a manner that they cannot be viewed without admiration: they are very large in proportion to the animal, transparent, and slightly iridescent. The earwig flies only by night, and it is not

without great difficulty that it can be made to expand its wings by day.

The usual food of the earwig consists of decayed fruit, and other vegetable substances; and it does not seem to be naturally carnivorous, though, if kept without proper nourishment, it will occasionally even attack and devour even its own species.

The popular dread in which this insect is held, on a supposition of its sometimes entering the cavity of the ear, and piercing the tympanum, is considered by some as problematical, though we believe there are instances of earwigs, which naturally creep into holes and apertures of every kind, having accidentally taken shelter in the ears of persons asleep, and occasioning great pain. The best means of expelling them, is to drop a small quantity of brandy or other spirit into the ear.

FORGE, properly signifies a small furnace, in which smiths and other artificers of iron or steel, &c. heat their metals red-hot, in order to soften and render them more malleable and manageable on the anvil.

Forge is also used for a large furnace, in which iron ore, taken out of the mine, is melted down; or it is more properly applied to another kind of furnace, where the iron ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGERY, is where a person counterfeits the signature of another, with intent to defraud; which by the law of England is made a capital felony. This law is now extended by statute to the counterfeiting of almost every written instrument which is either a security for money or a public document or voucher upon which money may be received, or by which any one may be defrauded of money by the act of imposing upon him such a false instrument To enumerate the several statutes upon the subject, would here be impossible. It is generally punished with the most rigorous severity. We shall add a few detached points with respect to the cases of forgery, which may be useful to explain cases of frequent occurrence.

Forgery may be committed by making a mark in the name of another person. It may be also committed in the name of a person who never had existence. Thus, indorsing a real bill of exchange, with a fictitious name, is forgery, although the use of a fictitious name was not essential to the negociation.

FORGING, in smithery, the beating or hammering iron on the anvil, after having first made it red-hot in the forge, in order to extend it into various forms, and fashion it into works.

FORM, *printers*, an assemblage of letters, words and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn. Every form is inclosed in an iron chase, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges.

FORMA *pauperis*, is when any person has cause of suit, and is so poor that he cannot support the usual charges of suing at law or in equity In this case, upon his making oath that he is not worth five pounds his debts being paid, and bringing a certificate from some lawyer that he has just cause of suit, the judge admits him to sue in *forma pauperis*, that is. without paying fees.

FORMATION. In geology, an assemblage of mineral strata or masses, connected with each other, so as to form one whole or system, without any notable interruption, either in the period or nature of their production.

FORMIC *acid*. It has long been known that ants contain a strong acid, which they occasionally emit; and which may be obtained from the ants, either by simple distillation, or by infusion of them in boiling water, and subsequent distillation of as much of the water as can be brought over without burning the residue. After this it may be purified by repeated rectifications, or by boiling to separate the impurities; or after rectification it may be concentrated by frost.

This acid has a very sour taste, and continues liquid even at very low temperatures. Its specific gravity is 1.1168 at 68°, which is much denser than acetic acid ever is. It has been used by quacks as a cure for the tooth-ache.

FORMICA, *ant*, an insect of the hymenoptera class. According to Linnæus there are 18 species. The insects of this genus live in large societies, and are divided into males, females, and neutrals. The latter constitute the great or general assortment, and conduct the business of the nest, which is usually placed at a small distance from the surface in some slight elevation either prepared by the insects themselves, or previously formed by some other animals, as moles, &c. They feed both on animal and vegetable substances, devouring the smaller kind of insects, caterpillars, &c. as well as fruits of different kinds. They wander about all day in search of food or materials for the nest, and assist each other in bringing home what is too heavy or large for such as have attempted it. They bring out of their nest, to expose to the warmth of the sun, the newly hatched larvæ, and feed them till they are able to provide for themselves. In the evening they consume together whatever has been collected during the day, and do not, as is commonly supposed, lay up any store for the winter During the winter they remain in a state of torpor, and in the spring recommence their labour.

FORMULA, or **Formulary**, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

Formula, in church history and theology, signifies a profession of faith.

FORSTERA, a genus of the triandria order, in the gynandria class of plants. There is but one species, an herbaceous plant of New Zealand.

FORT, in the military art, a small fortified place, environed with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-

bastions. A fort differs from a citadel, as this last is built to command some town.

FORTIFICATION, may be defined the science of military architecture; and when applied to a city, town, or other place, it consists in the art of putting any of these in such a posture of preparation, by means of ramparts, parapets, ditches, and outworks, that each individual part defends, and is defended by, some other parts, so that a small number of men can hold out for a considerable time against a multitude.

Fortification is either regular or irregular. The regular is that built in a polygon, the sides and angles of which are all equal, being commonly about a musket shot from each other. Irregular fortification, on the contrary, is where the sides and angles are not uniform, equidistant, or equal.

I. OF REGULAR FORTIFICATION.

Authors in general agree as to the form, but they differ in respect to the construction of the parts. The chief of those who have written on this art, are Pagan, Blondel, Vauban, Cœhorn, Scheiter, Muller, Robins, Belidor, Folard, Le Blond, marshal Saxe, Tielke, and Belair.

It must be recollected by every engineer, that his views are not to be confined to the mere art of fortification. He must be able to take advantage of natural strength and position, chains of mountains and streams of water.

Blondel fortifies within the given polygon: he establishes two sorts of fortification; the great one, whose exterior side is 200 toises, and the lesser one, 170; because he will not have the line of defence exceed 140 toises, which is the greatest musket-shot, nor less than 120 toises, not to increase the number of bastions. He begins by the diminishing angle, which may be found by taking 90 degrees from the angle of the polygon, and by adding 15 degrees to the third of the remainder.

Vauban's method is divided into little, mean, and great; the little is chiefly used in the construction of citadels; the mean, in that of all sorts of towns; and the great, in particular cases only.

Scheiter's method is divided into the great, mean, and small sort. The exterior side of the polygon for the great sort is 200 toises, the mean sort, 180, and the small 160. The line of defence in the first is 140 toises, the second 130, and the third 120. This line is always razant.

Count Pagan makes the flank perpendicular to the line of defence, and by that means the flank so raised covers as much as possible the face of the opposite bastion; but notwithstanding this apparent advantage, the flank becomes too small, and is too much exposed to the enemies' batteries. This engineer acquired great reputation during the several sieges which he assisted in conducting under Louis XIII. This system, as improved by Mallet, differs very little from marshal Vauban's first system. Count Pagan has pointed out the method of building casemates in a manner peculiar to himself.

Vauban has judiciously steered between these different methods. He has drawn his flank in such a manner, that it does not stand too much exposed, nor does its collateral line of defence extend too far from the direct line of defence. He has effected this by lengthening out his flank, and giving it a circular form.

It cannot be disputed that large and extensive flanks and demigorges are superior to narrow and confined ones. The more capacious the flank is the better calculated will it prove for the disposition of a formidable train of artillery. From this conviction many writers, in their proposed systems of fortification, have added a second flank, in order to augment the line of defence; but they did not foresee that this second flank is not only incapable of covering the face of the opposed bastion, except in a very oblique and insecure direction, but that the right flank, or the flank of the bastion, is thereby more exposed to the enemy's batteries.

The prevailing system is to make the flanks of the bastion as wide as possible; without having recourse to a second flank, unless absolutely necessary. Those gorges are likewise best which are most capacious, because they afford space in the bastion for the construction of entrenchments within.

All parts of a fortification, which stands exposed to the immediate attacks of a besieging enemy, must be strong enough to bear the boldest attempts, and the most vigorous impressions. This is self evident, because it must be manifest that works are erected round a place for the specific purpose of preventing an enemy from getting possession of it. It consequently follows, that flanked angles are extremely defective when they are too acute, since their points may be easily flanked and destroyed by the besiegers' cannon.

The Dutch construct at sixty degrees; but according to Vauban's method, no work should be under seventy-five degrees, unless circumstances and situation should particularly require it.

The following is Mr. Vauban's method with regard to the fortification of towns.

Inscribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let A B, fig. 7. Plate XVI, be one of the sides of half an hexagon, which bisect by the perpendicular C D; divide half of it A C into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is, six French feet; and therefore the whole side A B is supposed to be 180 toises. As the dividing a line into so many equal parts is troublesome and tedious, it is more convenient to have a scale of equal parts, by which the works may be constructed.

If, therefore, in this case, the radius be taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an hexagon inscribed; A B being bisected by the perpendicular C D as before, set off 30 toises from C to D, and draw the indefinite lines A D G, B D F; in which take the parts A E, B H, each equal to 50 toises; from the centre E describe an arc through the point H, meeting A D in G, and from the centre H, describe an arc through the

point E, meeting B D in F; or, which is the same, make each of the lines E G, H F, equal to the distance E H; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification. If, with a radius of 20 toises, there be described circular arcs from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts *ab*, *bc*, &c. together with these arcs, will present the outline of the ditch.

Definitions.

1. The part FEALN is called the bastion.
2. A E, A L, the faces of the bastion.
3. E F, L N, the flanks.
4. F G, the curtain.
5. F N, the gorge of the bastion.
6. A G, B F, the lines of defence.
7. A B, the exterior side of the polygon.
8. C D, the perpendicular.
9. Any line which divides a work into two equal parts is called the capital of that work.
10. *a, b, c,* the counterscarp of the ditch.
11. A, M, the flanked angles.
12. H, E, L, the angles of the shoulder, or shoulder only.
13. G, F, N, the angles of the flank.
14. Any angle whose point turns from the place is called saliant angle, such as A, M and any angle whose point turns towards the place, re-entering angle, such as *b*, F, N.
15. If there be drawn two lines parallel to the principal or outline, the one at 3 toises distance, and the other at 8 from it, then the space *yx* included between the principal one and the farthest distant is called the rampart.

And the space *x*, contained by the principal line and that near to it, and which is generally stained black, is called the parapet.

16. There is a fine line drawn within four feet of the parapet, which expresses a step call banquette.

All works have a parapet of 3 toises thick, and a rampart of from 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular constructions of engineers.

The parapet is a part of the rampart elevated from 6 to 7½ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

17. The body of the place is all that which is contained within this first rampart; for which reason it is often said to construct the body of the place; which means, properly, the construction of the bastions and curtains.

18. All the works which are constructed beyond the ditch, before the body of the place, are called outworks.

II. Of irregular fortification.

The most essential principle in fortification consists in making all the fronts equally strong, so that the enemy may find no particular advantage in attacking either of them. But this can only occur in a regular work, situated in a plain, or even ground; consequently there are but few places which are not irregular and the great art here is, to remedy the defects and inconveniences occasioned by this circumstance.

If the situation to be fortified is an old town, inclosed by a wall or rampart, the engineer ought to consider well all the different circumstances of the figure, position, and nature of the ground, and to regulate his plan accordingly, so as to avoid as many disadvantages, on one hand, and to obtain as many advantages, on the other as possible. If there is a rampart without towers, it must be decided whether bastions ought not to be added, and ravelins and counter-guards constructed. Special care must be taken to make all the sides of the polygon nearly equal, and that the length of the lines of defence do not exceed the reach of musket-shot. Wherever the sides are inaccessible, either on account of a precipice, or marshy ground, they may be made much larger than those which are easy of access.

Places built on mountains or rocks should never be large: for their use is generally to guard passes or inlets into a country, and it is difficult to provide for a large garrison under such circumstances. When fortifications are to be placed in the neighbourhood of the sea, for the purpose of protecting trade, the first thing to be considered is their situation, which ought to afford a good harbour for shipping. When M. Vauban fortified near rivers, he always made the exterior side next to the water much longer than any of the others: for as that part is not so liable to be attacked, great and manifest advantages were of course derived from this circumstance,

To illustrate this method of M. Vauban's, we here give the plan of Hunninghen. That place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side A B (fig. 8.) next to the river is 200 toises, and each of the others but 180.

About the space *a b c*, which lies before the front A B, is a stone wall; and the passages, are shut up with sluices, to retain the water in the ditches in dry seasons; and to prevent an enemy from destroying the sluice near the point *c*, whereby the water would run out and leave the ditches dry, the redoubt *y* was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulted from the river side, where the water is shallow in dry seasons.

The hornwork K, beyond the Rhine, was built to cover the bridge; but as this work cannot be well defended across the river, the hornwork H was made to support the other.

Before finishing the description of this plan, we shall shew how to find the long side A B. After having inscribed the two sides G E, G F, in a circle, draw the diameter C D, so as to be equally distant from the line joining the points E F. On this diameter set off 100 toises on

each side of the centre; from these points draw two indefinite perpendiculars to the diameter; then if from the points, E F, as centres, two arcs are described with a radius of 180 toises, their intersections A and B, with the said perpendiculars, will determine the long side A B. as likewise the other two F B and E A. In like manner may be found the long or short side of any polygon whatsoever.

The principal maxims of fortification are these, viz.

1. That every part of the works be seen and defended by other parts, so that the enemy cannot lodge any where without being exposed to the fire of the place.

2. A fortress should command all places round it; and therefore all the outworks should be lower than the body of the place.

3. The works farthest from the centre should always be open to those that are nearer.

4. The defence of every part should always be within the reach of musket-shot, that is, from 120 to 150 fathoms, so as to be defended both by ordnance and small fire-arms; for, if it is only defended by cannon, the enemy may dismount them by the superiority of their own, and then the defence will be destroyed at once; whereas, when a work is likewise defended by small-arms, if the one is destroyed, the other will still subsist.

5. All the defences should be as nearly direct as possible; for, it has been found by experience, that the soldiers are too apt to fire directly before them, without troubling themselves whether they do execution or not.

6. A fortification should be equally strong on all sides; otherwise the enemy will attack it in the weakest part, whereby its strength will become useless.

7. The more acute the angle at the centre is, the stronger will be the place.

8. In great places dry ditches are preferable to those filled with water, because sallies, retreats, succours, &c. are necessary; but, in small fortresses, wet ditches, that can be drained, are the best, as standing in need of no sallies.

FIELD-FORTIFICATION is the art of constructing all kinds of temporary works in the field, such as redoubts, field-forts, star-forts, triangular and square forts, heads of bridges, and various sorts of lines, &c. An army entrenched, or fortified in the field, produces, in many respects, the same effect as a fortress; for it covers a country, supplies the want of numbers, stops a superior enemy, or at least obliges him to engage at a disadvantage.

The knowledge of a field-engineer being founded on the principles of fortification, it must be allowed, that the art of fortifying is as necessary to an army in the field as in fortified places; and though the maxims are nearly the

can be readily obtained, viz. sand-bags, earth, and fascines ten feet long and one foot thick, which are fastened to the parapet, by means of five pickets driven obliquely into the bank.

When wood cannot be obtained for the fascines, the parapet must be clothed with turf, four inches thick, and a foot and a half square.

The palisades for fortifying the ditch ought to be nine or ten feet long and six inches thick.

The beams belonging to chevaux-de-frize should be twelve feet long, and six inches broad; the spokes seven feet long, four inches thick, and six inches distant from each other.

Gabions must be three or four feet high, and two or three feet in diameter.

FORTIN, **FORTLET**, or *field-fort*, a sconce or little fort, whose flanked angles are generally distant one from another 120 fathoms.

FORTS, *vitrified*, a very singular kind of structures found in the highlands and northern parts of Scotland, in which the walls have the appearance of being melted into a solid mass, so as to resemble the lava of a volcano, for which indeed they have been taken by several persons who have visited them.

FOSS, in fortification, a hollow place, commonly full of water, lying between the scarp and counterscarp, below the rampart; and turning round a fortified place or a post that is to be defended.

Foss-*way*, one of the four principal highways of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side.

FOSSIL, in natural history, denotes in general all things dug out of the earth: whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, reposited in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See MINERALOGY.

FOUL, or *foule*, in the sea language, is used when a ship has been long untrimmed, so that the grass-weeds, or barnacles grow to her sides under water. A rope is also foul when it is either tangled in itself or hindered by another, so that it cannot run or be over-hawled.

FOUL, imports also the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of those on board.

FOUNDATION, in architecture, is that part of a building which is under ground.

FOUNDATION, denotes also a donation or legacy, either in money or lands, for the maintainance and support of some community, hospital, school, lecture, &c.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. The founder of a church may preserve to himself the right of patronage, or presentation to the living.

FOUNDER, also implies an artist who casts metals in various forms, for different uses, as guns, bells, statues, printing characters, &c. whence they are denominated gun-founders bell-founders, figure-founders, letter-founders, founders of small works, &c.

FOUNDER, in the sea-language, a ship is said to founder, when she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, and at last sinks.

FOUNDERY, or *foundry*, the art of casting all sorts of metals into different forms. It likewise signifies the work-house in which these operations are performed.

Foundery *in small works, or casting in sand.* The sand used for casting small works is, at first, of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust on the mould, it at length becomes of a black colour. This sand is worked over, and over, on a board, with a roller, and a sort of knife, and then passed through a sieve. This done, they take a wooden board of a length and breadth proportioned to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and press them into the sand, so as to leave their impression there. Along the middle of the mould is laid half a small brass-cylinder, to form the chief canal for the metal to run through, when poured into the moulds; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished they take out the patterns, by first loosening them all around, that the sand may not give way.

They then proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and strewing mill-dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, on account of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

Some of these small-work founder's furnaces are like a smith's forge, others stand a few feet under ground, for the more easily and safely taking out a weighty pot of metal; which is done by means of circular tongs that grasp round the top of the crucible. When the metal is melted, the workman pours it through the chief canal of each mould, which conveys it to every distinct pattern.

When the moulds are cool, the frames are unscrewed, or unwedged, and the cast-work taken out of the sand, which sand is worked over again for other castings.

The mould, for very large articles, is made of wet tempered loam, and must be built up by degrees, in a pit sufficiently deep to allow the highest part of the casting to be lower than the furnace in which the metal is melted, as the metal must run from the furnace along a channel on the ground to the mould.

Bell Foundery. In casting bells, the composition which is used, is termed bell-metal, which is made of copper, with one-sixth of tin, the usual proportion for church-bells; in clock bells, the proportion of tin is smaller, and a little zinc is added, especially for very small bells. The dimensions of the core, and the wax of bells, especially if it be a ring of several bells that is to be cast, are not left to the caprice of the workman, but must be measured on a kind of scale, which gives the height, aperture, and thickness necessary for the several tones required. It need not be added, that it is on the wax that the several mouldings, and other ornaments and inscriptions to be represented in relievo on the outside of the bell are formed. The clapper, or tongue, is not properly a part of the bell, but is furnished from other hands. In Europe, it is usually of iron, and is suspended in the middle of the bell. In China, it is only a huge wooden mallet, struck by force of arm against the bell; whence there can be but little of that harmony so much admired in some of our sets of bells.

Foundery *of great guns and mortar-pieces.* The method of casting these pieces is little different from that of bells.

Foundery-*letter.* See **Type.**

FOUNT, or *font*, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted. Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When a printer orders a fount of five hundred, he means that the fount, consisting of letters, points, spaces, quadrates, &c. shall weigh 500*lb.* When he demands a fount of ten sheets, it is understood, that with that fount he shall be able to compose ten sheets, or twenty forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons 120*lb.* for a sheet, including the quadrates, &c. or 60*lb.* for a form, which is only half a sheet: not that the sheet always weighs 120*lb.*, or the form 60*lb*; on the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the cases. As, therefore, every sheet does not comprehemd the same number of letters, nor the same sort of letters, we must observe, that, as in every language some sounds recur more frequently than others, some letters will be in much more use, and oftener repeated than others, and consequently their cells or cases should be better stored than those of the letters which do not recur so frequently; thus, a fount does not contain an equal number of *a* and *b*, or of *b* and *c*, &c. the letter-founders have therefore a list or tariff, or, as the French call it, a police, by which they regulate the proportions between the different sorts of characters that compose a fount; and it is evident that this tariff will vary in different languages, but will remain the same for all sorts of characters employed in the same language.

FOURTEENTH, in music, the octave, replicate, of the seventh. A distance comprehending thirteeen diatonic intervals.

FOURTH, in music, a distance comprising three diatonic intervals: *i. e.* two tones and a half. The fourth is the third of the consonances in the order of their generation.

FOWL, denotes the largest sort of birds, whether domestic or wild, such as geese pheasants, partridges, turkeys, ducks, &c They are again divided into two kinds, viz, *land* and *water* fowl.

FOWLING. the art of taking or killing birds. It is either practised as an amusement by persons of rank and property, and then

principally consists in killing them with a light fire-arm, called a fowling-piece; and the diversion is secured to them by the game-laws; or it is practised for a livelihood, by persons who use nets and other apparatus The other artifices by which birds are taken, consist in imitating their voices, or leading them, by other means, into situations where they become entrapped by nets, or bird-lime, or otherwise.

Fowling *piece*, a light gun for shooting birds. That piece is always reckoned best which has the longest barrel, from 5½ to 6 feet, with a moderate bore; though every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal width from one end to the other; which may be proved by putting in a piece of pasteboard, cut of the exact roundness of the top; for if this goes down without stops or slipping, you may conclude the bore good.

FOX. See Canis.

Fox-*glove*. See Digitalis.

FRACTION. See Algebra.

FRACTURE, in surgery, a rupture of a bone, or a solution of continuity in a bone, when it is crushed or broken by some external cause.

FRAGARIA, the strawberry; a genus of the polygynia order, in the icosandria class of plants; and in the natural method ranking under the 35th order, senticosæ. The calyx is decemfid; the petals five; the receptacle of the seeds ovate, in the form of a berry and deciduous. There are three species, but only one is deserving of particular notice, viz. 1. the vesca, or cultivated strawberry. The principal varieties are, 1. The sylvestris, or wood strawberry, with oval sawed leaves, and small round fruit. 2. The Virginian scarlet, or Virginia strawberry with oblong oval sawed leaves, and a roundish scarlet coloured fruit. 3. The moschatta, or hautboy, or musky strawberry, having oval, lanceolate rough leaves, and large pale red fruit. 4. The chiloensis, or Chili strawberry, of which the Carolina is a variety with large, oval, thick, downy, leaves, large flowers, and very large firm fruit. 5. The alpina, alpine, or monthly strawberry, having small oval leaves, small flowers, and moderate-sized, oblong, pointed fruit. All these varieties are hardy, low, perennials, durable in root; but the leaves and fruit-stalks are renewed annually in spring. They flower in May and June, and their fruit comes to perfection in June, July, and August; the alpine kind continuing till the beginning of winter. They all thrive in any common garden soil, but best in a clayey soil, producing abundant crops annually without much trouble.

FRÆNUM, in anatomy, a term applied to some membraneous ligaments of the body.

Frænum *linguæ*, the ligament under the tongue, which sometimes ties it down too close to the bottom of the mouth; and then requires to be incised or divided, in order to give this organ its proper motion.

FRAISE, in fortification, a kind of defence consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, &c. and to prevent any approach or scalade,

FRANCHISE, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.

FRANK, or *franc*, meaning literally free from charges and impositions, or exempt from public taxes, has various significations in our ancient customs.

Frank, or *franc*, an ancient coin, of gold or silver, current in France. The value of the gold frank was somewhat more than that of the gold crown; the silver frank was a third of the gold one: this coin is now out of use, though the term is retained as the name of a money of account; being equivalent to 20 sols.

FRANKENIA, *sea-heath*, or *sea-chickweed*, a genus of the hexandria monogynia class of plants, the flower of which consists of five petals, with a plain limb: the fruit is an oval, unilocular capsule, covered by the cup, and containing a great many ovated very small seeds. There are three species of this weed.

FRANKINCENSE, is a gummy resin, the product of the juniperus lycia, consisting of equal parts of gum and resin; the first is soluble in water, the other in alcohol. It is brought from Turkey and the East Indies, but is principally collected in Arabia. It usually comes to us in drops, but in a very impure state, a hundred pounds not yielding more than from forty to fifty pounds of pure frankincense.

FRAUD, in law. All deceitful practices in defrauding or endeavouring to defraud another of his own right, by means of some artful device, contrary to the plain rules of common honesty, are condemned by the common law, and punishable according to the heinousness of the offence.

The distinction laid down, as proper to be attended to in all cases of this kind, is this, that in such impositions or deceits, where common prudence might guard persons from the offence, it is not indictable, but the party is left to his civil remedy; but where false weights or measures are used, or false tokens produced, or such measures taken to defraud or deceive, as people cannot by any ordinary care or prudence be guarded against, there it is an offence indictable.

Persons convicted of obtaining money or goods by false pretences, or sending threatening letters to extort money or goods, may be punished by fine and imprisonment, or by pillory, whipping, or transportation. 30 G. II. c. 24.

FRAXINUS, the *ash*, a genus of the diœcia order, in the polygamia class of plants, and in the natural method ranking under the 44th order, sepiariæ. There are four species, of which the most useful is the common ash, which is so well known that it needs no description. This tree flourishes best in groves, but grows very well in rich soil in open fields. It bears transplanting and lopping. In the north of Lancashire they lop the tops of these trees to feed the cattle in autumn when the grass is on the decline, the cattle peeling off the bark as food. It is hard and tough, and is much used to make the tools employed in husbandry. The ashes of the wood afford very good potash. The bark is used in tanning calf-skin.

FREEDOM *of a corporation*, the right of enjoying all the privileges and immunities belonging to it.

The freedom of cities, and other corporations is regularly obtained by serving an apprentice-

ship of seven years; but it is also sometimes purchased with money, and sometimes conferred by way of compliment.

FREEHOLD, may be in deed or in law. A freehold in deed is actual seisin of lands or tenements in fee-simple, fee-tail, or for life. A freehold in law is a right to such lands or tenements before entry or seisure.

FREESTONE, a whitish stone dug up in many parts of England, that works like alabaster, but is more hard and durable, being of excellent use in building, &c.

FREEZE, or *frieze,* in commerce, a coarse kind of woollen stuff, or cloth for winter wear; so called as being freezed or naped on one side.

Freezing, in philosophy, is the fixing a fluid body into a firm or solid mass by the action of cold.

Having under the article congelation explained the process of freezing water by means of the air-pump, we shall here subjoin a table of freezing mixtures which will be found capable of producing cold, without the aid of ice, sufficient for all useful and philosophical purposes, in any part of the world, and at any season.

Table of freezing mixtures.

	Mixtures.	Parts.	*Thermom. sinks.*
1.	Muriate of ammonia	5	from 50° to 10°.
	Nitre	5	
	Water	16	
2.	Muriate of ammonia	5	from 50° to 3°.
	Nitre	5	
	Sulphate of soda	8	
	Water	16	
3.	Sulphate of soda	5	from 50° to 0°.
	Diluted sulphuric acid	4	
4.	Snow	1	from 52° to 0°.
	Common salt	1	
5.	Snow or pounded ice	2	from 0° to—5°.
	Common salt	1	
6.	Potash	4	from 32° to—51°.
	Snow	3	
7.	Muriate of lime	3	from 32° to—50°.
	Snow	2	
8.	Muriate of lime	2	from 0° to—66°.
	Snow	1	
9.	Muriate of lime	3	from—40° to—73°.
	Snow	1	
10.	Diluted sulphuric acid	10	from—68° to—91°.
	Snow	8	

When any of these substances are to be employed as freezing mixtures, the salts should be used fresh crystallized, and reduced to fine powder · and it will perhaps be found most convenient to observe the proportions which are set down in the table. Suppose it is wanted to produce a degree of artificial cold equal to—50°, which is the temperature produced from 32° by the seventh freezing mixture. The substances employed, namely, the muriate of lime and the snow, must be previously cooled down to the temperature of 32°, or any degree below it. This may be done by placing them separately in the third freezing mixture, the sulphate of soda, and diluted sulphuric acid, which reduces the temperature from 50° to 3°; or in the fourth freezing mixture of snow and common salt, which reduces the temperature from 32° to 0°. The materials thus cooled down, are then to be mixed together as quickly as possible, when, if the experiment succeed, the temperature will fall from 32° to—50°, as in the seventh freezing mixture. The vessels which are employed for these processes should be very thin, and made of the best conductors of heat. Vessels of tin plate answer the purpose, and when acids are to be used, they may be lined with wax, which will secure them sufficiently against their action. They should be of no larger dimensions than just to contain the materials.

Freezing *point.* See **Thermometer.**

FREIGHT, or *fraight,* in navigation and commerce, is the consideration of money agreed to be paid for the use or hire of a ship, or, in a larger sense, the burthen of such ship.

The freight is most frequently determined for the whole voyage, without respect to time: sometimes it depends on time; in the former case it is either fixed at a certain sum for the whole cargo, or so much per ton, barrel, bulk, or other weight or measure, or so much per cent. on the value of the cargo.

FRESCO, a method of painting in relievo on walls, so as to endure the weather. It is performed with water-colours on fresh plaster; or a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

FRESHES, in sea-language, denote the impetuosity of an ebb-tide, increased by heavy rains, and flowing out into the sea, often discolouring it to a considerable distance, and forming a line that separates the two colours, and which may be distinctly perceived for a great length along the coast.

FRET, in architecture, a kind of knot, or ornament, consisting of two lists or fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

Fret, in heraldry, a bearing composed of six bars, crossed, and variously interlaced.

Fret, in music, signifies a kind of stop on some instruments, particularly bass-viols and lutes.

FRICTION, in mechanics, the rubbing of the parts of engines and machines against each other, by which means a great part of their effect is destroyed.

It is hardly possible to lay down general rules concerning the quantity of friction; since it depends upon a multiplicity of circumstances, as the structure, firmness, elasticity, &c. of the bodies rubbing against each other. Some authors make friction upon a horizontal plane, equal to one third of the weight to be moved; whilst others have found it to be considerably less.

Two objects must however be observed, *viz.* the loss of power which is occasioned by it, and the contrivances which have been made, and are in use, for the purpose of diminishing its effects.

A body of a horizontal plane should be capable of being moved by the application of the least force; but this is not the case, and the principal causes which render a greater or less quantity of force necessary for it are, 1st, the

roughness of the contiguous surfaces; 2dly, the irregularity of the figure, which arises either from the imperfect workmanship, or from the pressure of one body upon the other; 3dly, an adhesion or attraction which is more or less powerful according to the nature of the bodies in question; and 4thly, the interposition of extraneous bodies; such as moisture, dust, &c.

Innumerable experiments have been made for the purpose of determining the quantity of friction, which is produced in particular circumstances: But the results of experiments, which have been made do not agree; nor is it likely they should, since the least difference of smoothness or polish, or of hardness, or, in short, of any of the various concurring circumstances, produces a different result.

Mr. Vince, who has made many experiments on friction, infers,

1st, That friction is an uniformly retarding force in hard bodies, not subject to alteration by the velocity; except when the body is covered with cloth, woollen, &c. and in this case the friction increases a little with the velocity.

2dly, Friction increases in a less *ratio* than the quantity of matter or weight of the body. This increase, however, is different for the different bodies, more or less; nor is it yet sufficiently known, what proportion the increase of friction bears to the increase of weight.

3dly, The smallest surface has the least friction, the weight being the same. But the ratio of the friction to the surface is not yet accurately known.

The methods of obtaining the important object of diminishing the friction, are of two sorts, *viz.* either by the interposition of particular unctuous, or oily substances between the contiguous moving parts, or by particular mechanical contrivances. Olive-oil is the best, and perhaps the only substance that can be used in small works, as in watches and clocks, when metal works against metal. But in large works the oil is liable to drain off, unless some method is adopted to confine it. Therefore, for large works tallow is mostly used, or grease of any sort, which is useful for metal, as well as for wood. In the last case tar is also frequently used. The mechanical contrivances which have been made, and are in use, for the purpose of diminishing the effects of friction, consist either in avoiding the contact of such bodies as produce much friction, or in the interposition of rollers, *viz.* cylindrical bodies, between the moving parts of machines, or between moving bodies in general. Such cylinders derive, from their various size and application, the different names of rollers, friction wheels, and friction rollers.

FRIGATE, among seamen, a ship of war, light built, and that is a good sailer. All ships of war that carry from 20 to 50 guns are called frigates.

FRINGELLA, in ornithology, a genus belonging to the order of passeres. The bill is conical, straight, and sharp pointed. There are no less than 108 species comprehended under this genus, distinguished principally by varieties in their colour. The following are the most remarkable.

1. The *carduelis*, or goldfinch, with the quill feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. The young bird, before it moults, is grey on the head; and hence it is termed by the bird-catchers a grey-pate. There is a variety of goldfinches called by the London bird-catchers a cheverel, from the manner in which it concludes its jerk. It is distinguished from the common sort by a white streak, or by two, sometimes three, white spots under the throat. The note of the goldfinch is very sweet, and they are much esteemed on that account, as well as for their great docility. Towards winter, they assemble in flocks, and feed on seeds of different kinds, particularly those of the thistle. They are fond of orchards, and frequently build in an apple or pear-tree; the nest is very elegantly formed of fine moss, liverworts, and bents, on the outside; lined first with wool and hair, and then with the goslin or cotton of the sallow. The goldfinch lays five white eggs, marked with deep purple spots on the upper end, and has two broods in the year.

2. The *cœlebs*, or chaffinch, has black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It has its name from delighting in chaff. This species entertain us agreeably with its song very early in the year, but towards the latter end of the summer assumes a chirping note. Both sexes continue with us the whole year. They lay four or five eggs of a dull white colour, tinged and spotted with deep purple. They are caught in plenty in flight-time.

3. The *montifringilla*, or brambling, has a yellow bill tipped with black; the head, hind part of the neck, and back, are black; the throat, fore part of the neck, and breast, pale rufous orange; lower part of the breast and belly white; the quill feathers brown with yellowish edges; the tail a little forked: the legs grey. This species migrates into England at certain seasons, but does not build here. It is frequently found among chaffinches, and sometimes come in vast flocks. They are also seen at certain times in vast clouds in France. They are said to be particularly fond of beech mast, but will also eat seeds of various other kinds. This species is found throughout Europe, and is common in the pine forests of Russia and Siberia.

4. The *domestica*, or sparrow, has the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. These well-known birds are proverbially salacious, and have three broods in a year. They are every where common about houses, and build in every place they can find admittance to. They make a slovenly nest; generally a little hay ill put together, but lined well with feathers, where they lay five or six eggs of a reddish white colour spotted with brown. They sometimes build in the neighbouring trees, in which case they take more pains with the nest: and not unfrequently they expel the martins from theirs, to save the trouble of constructing one of their own.

5. The *spinus*, or siskin, has the prime feathers of the wings yellow in the middle, and the four first chief tail-feathers without spots; but they are yellow at the base, and black at the points. In Sussex it is called the barley-

bird, because it comes to them in barley-seed time. We are informed that it visits these islands at very uncertain times, like the gross-beak, &c. It is a very tame and docile species, and is often kept and paired with the Canary-bird, with which it breeds freely.

6. The *linota*, or linnet, has the bottom of the breast of a fine blood-red, which heightens as the spring advances. These birds are much esteemed for their song. They feed on seeds of different kinds, which they peel before they eat; the seed of the linum or flax is their favourite food; whence the name of the linnet tribe. They breed among furze and white thorn; the outside of their nest is made with moss and bents, and lined with wool and hair. They lay five whitish eggs, spotted like those of the goldfinch.

7. The *cannabina*, or greater red-pole, is less than the common linnet, and has a blood-coloured spot on the fore-head, and the breast of the male is tinged with a fine rose-colour. These birds are frequent on our sea-coasts, and are often taken in flight-time near London: it is a familiar bird, and is cheerful soon after it is caught.

8. The *linaria*, or lesser red-pole, is about half the size of the last, with a rich spot of purplish red on the forehead; the breast is of the same colour, but less bright. This species is known about London by the name of stone red-pole. Whole flocks of them, mixed with the siskin, frequent places where alders grow, for the sake of picking the catkins. This species seems to be in plenty throughout Europe, from the extreme parts of Russia to Italy. It is common in Greenland, and in America it is likewise well known.

9. The *montium*, or twite, is about the size of a linnet. It has the feathers of the upper part of the body dusky, those on the head edged with ash-colour, the others with brownish red: the rump is pale crimson; the wings and tail are dusky, the tips of the greater coverts and secondaries whitish; the legs pale brown. The female wants the red mark on the rump. Twites are taken in the flight-season near London, along with other linnets.

10. The *Canaria*, or Canary-bird, has a whitish body and bill, with the prime feathers of the wings and tail greenish. It was originally peculiar to those islands to which it owes its name; the same that were known to the ancients by the addition of the Fortunate.

FRIT, or **Fritt**, in the glass manufacture, is the matter or ingredients of which glass is to be made, when they have been calcined or baked in a furnace.

There are three kinds of frit: the first crystal frit, or that for clear glass, is made with salt of pulverine and sand. The second and ordinary frit is made of the bare ashes of pulverine or barilla, without extracting the salt from them. This makes the ordinary white or crystal glass. The third is frit for green glasses, made of common ashes, without any preparation.

FRITH, in its most usual acceptation, signifies an arm of the sea; such are the frith of Forth or of Edinburgh, the frith of Clyde, Murray frith, &c.

FRITILLARIA, *fritillary*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. There are five species, all of them bulbous rooted flowery perennials, producing annual stalks from about one foot to a yard or more high, terminated by large, bell-shaped, liliaceous flowers, of a great variety of colours.

FRIZING *of cloth*, a term in the woollen manufactory, applied to the forming of the nap of a cloth or stuff into a number of little hard burrs or prominences, covering almost the whole ground. This process is now performed by machinery, which renders it more perfect than could be done by the old method.

FROG. See Rana.

Frog-*fish* of Surinam, a very singular animal, of which there is no specimen in the British or any public museum. In Surinam these fishes are called jakjes. They are cartilaginous, of a substance like our mustela, and exquisite food: they are formed with regular vertebræ, and small bones all over the body divided into equal parts; are first darkish, and then grey; their scales make a beautiful appearance.

FROST. See Congelation and Freezing.

FROTH-*spit*, or **Cuckow-spit**, a name given to a white froth or spume, very common in the spring. It forms the nidus of a species of cicada.

FRUSTUM, in mathematics, a part of some solid body separated from the rest.

The frustrum of a cone is the part that remains, when the top is cut off by a plane, parallel to the base, and is otherwise called a truncated cone.

The frustum of a globe or sphere is any part of it cut off by a plane, the solid contents of which may be found by this rule. To three times the square of the semidiameter of the base add the square of its height; then multiplying that sum by the height, and this product multiplied by .5236, gives the solidity of the frustum.

FUCUS, a name given by the ancients to certain dyes and paints. By this name they called a purple sea-plant used by them to dye woollen and linen cloths of that colour. The dye was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. This is the account Theophrastus gives of it.

Fucus, in the Linnæan system of botany, is a genus of the order of algæ, belonging to the cryptogamia class of plants. The most remarkable species are,

1. The *serratus*, serrated fucus, or sea-wrack. This is frequent at all seasons of the year upon the rocks at low-water-mark. It consists of a flat, radical leaf, about two feet long; the branches half an inch wide, serrated on the edges with dents of unequal size. A small species of coralline, called by Linnæus sertularia pumila, frequently creeps along the leaf. All the species of fucus afford a quantity of impure alkaline salts; but this much less than some others, eight ounces of the ashes yielding only three of fixed salt.

2. The *vesiculosus*, bladder fucus, common sea-wrack, or sea-ware It grows in great abundance on the sea-rocks about low-water-mark. It has the same habit, colour, and substance as the foregoing, but the edges of the

leaf havs no serratures. In the surface are spherical, or oval bladders hairy within, growing generally in pairs, but often single in the angles of the branches, which are most probably air-bladders to buoy up the plant in the water. On the summits of the leaves appear tumid vesicles about three quarters of an inch long, sometimes oval and in pairs, sometimes single and bifid, with a clear viscid mucus interspered with downy hairs. This species is an excellent manure for land; for which purpose it is often applied in the maritime parts of Scotland and other countries. But the most beneficial use to which the fucus vesiculosus is applied, is in making potash or kelp, a work much practised in the Western Isles. There is great difference in the goodness and price of this commodity, and much care and skill required in properly making it. That is esteemed the best which is hardest, finest grained, and free from sand or earth.

Its virtues in the medical way have been much celebrated by Dr. Russell, in his Dissertation concerning the use of Sea-water in the Diseases of the Glands.

3. The *plicatus*, matted or Indian-grass fucus, grows on the sea-shores in many places both of England and Scotland. It is generally about three or four, but sometimes six inches long. Its colour, after being exposed to the sun and air, is yellowish or auburn; its substance pellucid, tough, and horny; resembling Indian grass.

4. The *palmatus*, palmated or sweet fucus, commonly called dulse or dilse. This grows plentifully on the sea-coasts of Scotland and the adjoining islands. Its substance is membranaceous, thin, and pellucid; the colour red, sometimes green, with a little mixture of red; its length generally about five or six inches, but varies from three inches to a foot; its manner of growth fan-shaped, or gradually dilated from the base upwards.

5. The *esculentus*, eatable fucus, or bladder-locks, commonly called tangle in Scotland, is likewise a native of the British shores. It is commonly about four feet long, and seven or eight inches wide. The substance is thin, membranaceous, and pellucid; the colour green or olive. The root consists of tough cartilaginous fibres.

6. The *saccharinus*, sweet fucus, or sea-belt, is very common on the sea-coast. The substance of this is cartilaginous and leathern, and the leaf is quite ribless.

7. The *ciliatus*, ciliated or ligulated fucus, is found on the shores of Ionia and other places, but is not common. The colour of this is red, the substance membranous and pellucid, without rib or nerve; the ordinary height of the whole plant about four or five inches.

8. The *prolifer*, or proliferous fucus, is found on the shores of the western coast, adhering to shells and stones. The colour is red; the substance membranaceous, but tough, and somewhat cartilaginous, without rib or nerve, though thicker in the middle than at the

[illegible] The *pinnatifidus* jagged fucus, or pepper-dilse, is frequent on sea-rocks which are covered by the tides both on the eastern and western coasts. It is of a yellow olive-colour, often tinged with red. The substance is cartilaginous, but yet tender and transparent; the height about two or three inches.

10. The *plocamium*, or pectinated fucus, is frequent on the sea-rocks, and in basins of water left by the recess of the tides. Its natural colour is a most beautiful bright red, or purple, but is often variegated with white or yellow. Its substance is cartilaginous, but extremely thin, delicate, and transparent; its height commonly about three or four inches.

11. The *filum*, thread-fucus, or sea-laces, is found on the sea-rocks, and waving under the water like long strings, frequent on many parts of the coast. The substance of this is opaque and cartilaginous, but not difficult to be broken. The colour, when recent, a dull olive-green; when dry, nearly black; and, when exposed for some time on the shores to the sun and air, it becomes yellow, straw-coloured, or white.

12. The *giganteus*, or gigantic fucus, is a native of the Straits Le Maire, and grows on rocky ground, which in those countries is distinguished from sand or ooze by the enormous length of the sea-weeds that grow upon it. The leaves are four feet long, and some of the stalks, though not thicker than a man's thumb, are 120.

FUEL. Dr. Black divides fuel into five classes; the first comprehends the fluid inflammable bodies; the second, peat or turf; the third, charcoal of wood; the fourth, pit-coal charred: and the fifth, wood, or pit-coal, in a crude state, and capable of yielding a copious and bright flame.

FUGUE, in music, a term derived from the Latin word fuga, a flight, and signifying a composition either vocal, or instrumental, or both, in which one part leads off some determined succession of notes called the subject, which, after being answered in the fifth and eighth by the other parts, is interspersed through the movement, and distributed amid all the parts in a desultory manner, at the pleasure of the composer; sometimes accompanied by other adventitious matter, and sometimes by itself. There are distinct descriptions of fugues; the simple, the double, and the counter fugue.

FUIRENA, a genus of the triandria monogynia class and order. There is one species, a grass of Surinam.

FULCRUM, in mechanics, the prop or support by which a lever is sustained. See Mechanics.

FULGORA, or lantern-fly, an insect belonging to the hemiptera order.

1. The *fulgora lanternaria*, or Peruvian lantern-fly, is undoubtedly one of the most curious of insects. It is of a very considerable size, measuring nearly three inches and a half from the tip of the front to that of the tail, and about five inches and a half between the extremities of the wings when expanded: the body is of a lengthened oval shape, and divided into several rings or segments; the head is nearly equal to the length of the rest of the animal; the ground-colour is an elegant yellow, with a strong tinge of green in some parts, and marked with numerous bright red-brown stripes and spots; the wings are very large, of a yellow colour, elegantly varied with brown undulations and spots, and the lower pair are decorated by a very large spot on the

middle of each, the iris or border of the spot being red, and the centre half red and half white; the head or lantern is pale yellow, with longitudinal red stripes. This beautiful insect is a native of Surinam and many other parts of South America, and during the night diffuses so strong a phosphoric splendour from its head or lantern, that it may be employed for the purpose of a candle or torch; and it is said that three or four of the insects, tied to the top of a stick, are frequently used by travellers for that purpose.

2. The *fulgora candelaria* is a much smaller species than the preceding, and is a native of China. It measures nearly two inches in length, and two inches and a half in breadth, with the wings expanded: the body is oval, and the head produced into a long horn-shaped process: the colours are very elegant, the head and horn being of a fine reddish brown or purple, and covered with numerous white specks; the thorax is of a deep or orange-yellow, and the body black above, but deep yellow beneath; the wings are oval, the upper pair blackish, with very numerous and close-set green reticulations, dividing the whole surface into innumerable squares or marks, and are farther decorated by several yellow bars and spots; the under wings are orange-coloured, with broad black tips.

3. *Fulgora diadema* is an Indian species, and is distinguished by having a long, spiny, front, with a triple division at the tip; its colour is brown, with red and yellow variegations; in size it is nearly similar to that of the preceding species.

FULICA, the *gallinule* and *coot*, in ornithology, a genus of birds of the order of grallæ. There are 25 species, 18 of which belong to the gallinule division, distinguished by having the toes furnished with broad scalloped membranes, and seven comprehend the coots which have the toes divided to their origin. The following species are among the most distinguished.

1. The *chloropus*, or common gallinule, is in length about 14 inches, and has a bald forehead and broad flat toes. It gets its food on grassy banks, and borders near fresh waters. It builds upon low trees and shrubs by the water-side, breeding twice or thrice in a summer, and, when the young are grown up, drives them away to shift for themselves.

2. The *porphyrio*, or purple gallinule, is about the size of a domestic fowl. It is more or less common in all the warmer parts of the globe. The female makes her nest among the reeds in the middle of March; lays three or four eggs, and sits from three to four weeks. It will feed on many things, such as fruit, roots and grain: but will eat fish with avidity, dipping them into the water before it swallows them.

3. The *atra* or common coot, has a bald forehead, a black body, and lobated toes, and is about 15 inches in length. They frequent lakes and still rivers; making their nests among the rushes, with grass, reeds, &c. floating on the water, so as to rise and fall with it. They lay five or six large eggs, of whitish hue, sprinkled over with rust-coloured spots. The young, when just hatched, are very deformed, and the head mixed with a red coarse down. In winter the channel near Southampton is sometimes almost covered with them. Their food is small fish and water-insects; but they will sometimes eat the roots of the bulrush: they are said likewise to eat grain.

4. The *aterrima*, or greater coot, is of a larger size than the last, and its plumage is blacker. This species is said to be found in Lancashire and Scotland; but is more plentiful on the continent, being found in Russia and the western parts of Siberia.

FULLER, a workman employed in the woollen manufactories to mill or scour cloths, serges, and other stuffs, in order to render them more thick, compact, and durable.

FULLER'S *earth*, in natural history, a species of clay, of a greyish ash-coloured brown, and has generally something of a greenish cast. It is hard and firm, of a compact texture, of a rough surface that adheres slightly to the tongue. It is very soft to the touch, not staining the hands, nor breaking easily between the fingers. Its constituents are, 53 silica, 10 alumina, 1.25 magnesia, 0.50 lime, 0.10 muriate of soda, trace of potash, oxide of iron 9.75, water 24.—*Klaproth.* Bergmann found 24 alumina, and only 0.7 oxide of iron. In England it occurs in beds, sometimes above, sometimes below, the chalk formation; at Rosswein in Upper Saxony, under strata of greenstone slate; and in different places in Germany it is found immediately under the soil. The best is found in Buckinghamshire and Surry.

FULLING, the art or act of cleansing, scouring, and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer; called also milling. The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called a fulling or scouring-mill. These mills, except in what relates to the mill-stones and hopper, are much the same with corn-mills: and there are even some which serve indifferently for either use corn being ground, and cloths fulled, by the motion of the same wheel. Whence in some places, particularly in France, the fullers are called millers; as grinding corn and milling stuffs at the same time.

The method of fulling cloths and woollen stuffs with soap is this: A coloured cloth, of about 45 ells, is to be laid in the usual manner, in the trough of a fulling mill, without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required, one half of which is to be melted in two pails of river or spring water. This solution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough: and thus it is to be fulled for at least two hours; after which it is taken out and stretched. This done, the cloth is immediately returned into the same trough, without any new soap, and there fulled two hours more. Then taking it out, they wring it well, to express all the grease and filth. After the second fulling, the remainder of the soap is dissolved as in the former, and cast four different times on the cloth, remembering to take out the cloth every two hours to stretch it. When it is sufficiently fulled, and brought to the quality and thickness required it is scoured in hot water, in the trough till it

is quite clean. As white cloths full more easily and in less time than coloured ones, a third part of the soap may be spared.

FULMINATION. In a variety of chemical combinations it happens, that one or more of the principles assume the elastic state with such rapidity, that the stroke against the displaced air produces a loud noise. This is called fulmination, or much more commonly, detonation.

Fulminating gold, and fulminating powder, are the most common substances of this kind, except gunpowder. For the latter of these, see the article GUNPOWDER. The fulminating powder is made by triturating in a warm mortar, three parts by weight of nitre, two of carbonate of potash, and one of flowers of sulphur. Its effects, when fused in a ladle, and then set on fire, are very great. The whole of the melted fluid explodes with an intolerable noise, and the ladle is commonly disfigured, as if it had received a strong blow downwards.

If a solution of gold be precipitated by ammonia, the product will be fulminating gold. Less than a grain of this, held over the flame of a candle, explodes with a very sharp and loud noise. This precipitate, separated by filtration, and washed, must be dried without heat, as it is liable to explode with no great increase of temperature; and it must not be put into a bottle closed with a glass stopple, as the friction from this would expose the operator to the same danger.

FULMINATING *silver*.—Dissolve fine silver in pale nitric acid, and precipitate the solution by lime water; decant the fluid, mix the precipitate with liquid ammonia, and stir it till it assumes a black colour; then decant the fluid, and leave it in the open air to dry. This product is fulminating silver, which when once obtained cannot be touched without producing a violent explosion. It is the most dangerous preparation known, for the contact of fire is not necessary to cause it to detonate. It explodes by mere touch. Its preparation is so hazardous, that it ought not to be attempted without a mask, with strong glass eyes, upon the face. No more than a single grain ought at any time to be tried as an experiment. This was invented by Berthollet.

M. Chenevix has invented a fulminating silver, not so dangerous as that just mentioned. It is thus prepared: Diffuse a quantity of alumina through water, and let a current of chlorine gas pass through it for some time. Then digest some phosphate of silver on the solution of the chlorite of alumnia, and evaporate it slowly. The product obtained will be a hyperchlorate of silver, a single grain of which, in contact with two or three of sulphur, will explode very violently with the slightest friction.

FULMINATING *mercury*. The mercurial preparations which fulminate, when mixed with sulphur, and gradually exposed to a gentle heat, are well known to chemists: they were discovered, and have been fully described, by Mr. Bayen.

Brugnatelli and Van Mons have likewise produced fulminations by concussion, as well by nitrate of mercury and phosphorus as with phosphorus and most other nitrates. Cinnabar likewise is amongst the substances which, according to Fourcroy and Vauquelin, detonate by concussion with chlorate of potash.

M. Ameilon had, according to Berthollet, observed, that the precipitate obtained from nitrate of mercury, by oxalic acid, fuses with a hissing noise.

But mercury, and most, if not all its oxides, may, by treatment with nitric acid and alcohol, be converted into a whitish crystallized powder, possessing all the inflammable properties of gun-powder, as well as many peculiar to itself. This discovery was made by Mr. Howard.

FUMIGATION, in medicine, a process by means of which the nitrous and other mineral acids, in a state of vapour, are dispersed through the apartments of those who lie sick of infectious fevers. When this fumigation is undertaken on board ships, the ports and scuttles are closed, a number of pipkins, containing hot sand, are procured, and into each is plunged a small tea-cup, containing half an ounce of sulphuric acid. As soon as the acid is properly heated, an equal quantity of pulverised nitre is added, and the mixture stirred with a glass rod. The vapour resulting from the decomposition of nitre ascends, and is by the nurses conducted to every part of the apartment, which not only abates the malignity of the fever, but effectually stops the progress of infection.

FUNCTION, the act of fulfilling the duties of any employment.

FUNCTION, *animal*, applied to the actions of the body, is by physicians divided into vital, animal, and natural. The vital functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The natural functions are such as it cannot subsist any considerable time without them, as the digestion of the aliment, and its conversion into blood. Under animal functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion.

FUNDS, *public*. When the practice was first adopted of borrowing money for the state, the produce of some particular tax was generally appropriated, as the fund out of which the principal and interest of the debt was to be discharged. The possession of the acknowledgment given by government for the money advanced, establishing a right to receive the payments from the fund originally agreed upon, the sale of these securities was considered as a sale of the claim upon the fund, and as the acknowledgments given were of different kinds, the general appellation of the provision on which they rested was found more convenient for purposes of business: thus the sale and purchase of the government securities was commonly called the sale or purchase of the public funds, till at length the expression has so far varied from its original signification, that instead of meaning the revenue out of which public debts or the interest of them is payable, it denominates the capital of such debts, in which sense it is generally used.

FUNDAMENTAL *note*, in music, the principal note in a song, or composition, to which all the rest are in some measure adapted, and by which they are swayed · it is otherwise called the key to the song

FUNGI, *mushrooms*. The name of one of the seven families, or tribes, into which all vegetables are divided by Linnæus in his Philosophia Botanica. In the sexual system, they constitute the fourth order of the class cryptogamia. It is the name also of the fifty-eighth order of the Fragments. These plants are rarely branched, sometimes creep, but are most commonly erect. Such as are furnished with branches have them of a light spungy substance like cork. Mushrooms differ from the fuci in that those, which, like the fuci, have their seeds contained in capsules, are not branched as that numerous class of sea-weed is. The greatest part of mushrooms have no root; some, in their stead, have a number of fibres, which, by their inosculations, frequently form a net with unequal meshes, some of which produce plants similar to their parent vegetable. The stamina in these plants are still undetermined. The seeds are either spread over the surface of the plant, or placed in cavities which are open, and resemble the open capsules of some of the fuci. In mushrooms which are branched, the seeds are frequently visible by the naked eye, and always to be distinctly observed with the assistance of a good microscope. See Acaricus.

FUNGUS, in surgery, denotes any spungy excrescence.

FURLONG, a long measure, equal to ⅛ of a mile or forty poles. It is also used in some law books, for the eighth part of an acre.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, an utensil to raise and maintain a vehement fire in, whether of coal or wood; they are built of bricks, made of sand and clay, or of cast-iron, or of iron plates, which are coated to the thickness of an inch with Windsor loam; various kinds of fire-proof furnaces, for making small experiments, may be prepared from black-lead crucibles.

The burning of the fuel is kept up in the furnace either by a natural current of air, which is caused by the fire itself, and such a furnace is called an air wind-furnace; or it is done by compressed air, conveyed to the furnace by a large bellows, as in blast-furnaces. See Laboratory.

FURR, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on, and used as a part of dress by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, rabbit, &c.

Furrs, in heraldry, a bearing which represents the skins of certain beasts, used as well in the doublings of the mantles belonging to the coat armours, as in the coat-armour themselves.

FURZE, or *furze-bush*. See Ulex.

FUSANUS, a genus of the polygamia monœcia class and order. There is one species, a tree of the Cape.

FUSEE, in clock-work, is that part drawn by the spring, and about which the chain or string is wound.

FUSILEERS, in the British service, are soldiers armed like the rest of the infantry, with this difference only, that their musquets are shorter and lighter than those of the battalion and the grenadiers.

FUSION, the action of fire, or more properly, of caloric, on solid bodies, by which they are caused to pass into the state of fluidity; and a body rendered liquid by fire is said to be in fusion, to flow, to melt.

Some bodies cannot be rendered fluid by any degree of heat which we are able to produce. These are called infusible, apyrous or fire-proof. Several of them may, however, be fused by adding other bodies, which on account of this property are called fluxes. Such addition is called at the smelting-works dressing of the ores.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as if it was whaled on one side.

FUSTIC, or *yellow wood*. This wood, the *morus tinctoria*, is a native of the West Indies. It affords much yellow colouring matter, which is very permanent.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

G.

G. In grammar, is the seventh letter, and fifth consonant of the English alphabet. It has two sounds, viz. the hard sound as in the word *game*: and the soft as in *George*.

As a numeral, it anciently denoted 400; and with a dash over it, thus, $\overline{\text{G}}$, 400,000. In music it is the mark of the treble cleft; and, from its being placed at the head of Guido's scale, that scale too; [illegible] name of gamut.

GABEL, a word met with in old records, signifying a tax, rent, custom, or service, paid to the king, or other lord.

GABIONS, in fortification, baskets made of ozier-twigs, of a cylindrical form, six feet high, and four wide; which being filled with earth, serve as a shelter from the enemy's fire. See Fortification.

GABRES, Guebres, or Gaurs, worshippers of fire, a religious sect which has subsisted in Asia from a very ancient period. They are met with principally in Surat, Bombay, and along the coast of Malabar. The moral character of these people is universally esteemed; they are quiet, inoffensive, and industrious, and are most respected where they are best known. Their munificence and liberality to men of all tribes, is perhaps unexampled in the history of mankind. They do not bury their dead, but expose them to birds of prey in a kind of circular building, called a *dakhme*, which is open

at top: these buildings present a spectacle too horrible to bear description, but which is viewed by the Gaurs with enthusiastic delight.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore

GAD-FLY, or *breeze-fly* See OESTRUS.

GADOLINITE, a mineral first found in a white felspar in the quarry of Ytterby in Sweden, and received the name gadolinite, because Gadoline was the chemist who first ascertained its composition. Colour perfect black, passing sometimes to brown. Found in mass. Fracture conchoidal. Scratches quartz. Brittle. With borax it melts into a topaz-yellow glass. Sp. gr. 4.0 to 4.2. It intumesces very much before the blowpipe, and at length melts into an imperfect slag, which is magnetical. It loses its colour in nitric acid, and gelatinizes. Its constituents are 25.8 silica, 45 yttria, 16.69 oxide of cerium, 10.26 oxide of iron, 0.60 volatile matter.

GADUS, *cod*, in ichthyology, a genus of fishes belonging to the order of jugulares. There are 17 species, the principal of which are,

1. *Gadus morhua*, or common cod. This highly important and prolific species is an inhabitant of the northern seas, where it resides in immense shoals, performing various migrations at stated seasons, and visiting in succession the different coasts of Europe and America.

The general rendezvous of the cod-fish is on the banks of Newfoundland, and the coasts of Cape Breton, Nova Scotia, and New England. They prefer those situations on account of the quantity of worms produced in those sandy bottoms, but another cause of this attachment to those spots is their vicinity to the polar seas, where they return to spawn: there they deposit their roe in full security, but want of food forces them, as soon as the first more southern seas are open, to repair thither for subsistence. Few are taken north of Iceland, but on the

The cod grows to a very large size. Mr. Pennant instances a specimen taken on the British coast which weighed 78 lbs. and measured 5 feet 8 inches in length, and 5 feet in girth round the shoulders; but the general weight is from about 14 to 40 pounds.

The cod is of a moderately long shape, with the abdomen very thick and prominent: the head is of moderate size, and the eyes large: the jaws of equal length, the lower one bearded at the tip by a single cirrus; in the jaws and palate are numerous sharp teeth: the dorsal and anal fins are rather large, the pectoral small: the ventral small and slender: the tail of moderate size and even at the end, the first ray on each side being short and bony. The usual colour of this fish is cinerous on the back and sides, and commonly spotted with yellow: the belly silvery; but the colours occasionally vary very considerably; the lateral line, which is one of the principal distinctive [illegible], whitish, and the scales are somewhat larger than in others of the genus.

The food of the cod is either small fish, worms, testaceous or crustaceous animals, such as crabs, &c. Its digestion is so powerful as to dissolve the greatest part of the shells it swallows. The fishermen are well acquainted with the use of the air bladder or sound of this fish, and dexterously perforate the living fish with a needle, in order to let out the air contained in that part. The sounds when salted, are reckoned a delicacy. A species of isinglass is also prepared from this part of the fish by the natives of Iceland.

2. *Gadus æglefinus*, or haddock, is distinguished from the rest of this genus by having a forked tail, and the lower jaw longer than the upper: the colour of the body is silvery, with a dusky cast on the back: the lateral line is black, and on each side at some distance beyond the head, and above the pectoral fins, is a black spot: the tip of the lower jaw is furnished with a cirrus: the eyes are large; the scales small, round, and closely attached to the skin.

This species is a native of the northern seas, where, like the cod, it assembles in prodigious shoals, visiting particular coasts at stated seasons; the shoals are sometimes near six miles in length, and more than a mile in breadth. The haddock is taken in vast quantities about Heligoland, and thence sent to Hamburgh. Its food consists of small fishes, worms, and sea insects. It spawns in the month of February.

3. *Gadus callarius*, or dorse, is a somewhat smaller species than the haddock, rarely exceeding the weight of two pounds.

The head is smaller than that of the haddock, and is marked by several spots, which in the summer are generally brown, and in the winter black.

The dorse is a native of the northern seas, as well as of the Mediterranean and the Baltic. It is taken both by the line and the net, and is highly esteemed as an article of food.

4. *Gadus barbatus*, or whiting-pout, according to Mr. Pennant, never grows to a large size, rarely exceeding a foot in lengh, and is distinguished from all others by its great depth; one of the size above mentioned being near

5. *Gadus minutus*, or poor, is a small species, seldom exceeding six or seven inches in length, and of a more slender form than any of the preceding kinds. It is found in the Baltic and the Mediterranean.

6. *Gadus merlangus*, or whiting, with three dorsal fins, but with a beardless mouth. The whiting is the most delicate as well as the most wholesome of the genus, but does not grow to a large size, the usual length being about ten or twelve inches, and the largest scarcely exceeding twenty. It is a fish of an elegant make: the body is rather long, and covered with small, round silvery scales: the head and back are of a pale brown, and the sides slightly streaked with yellow. This fish is an inhabitant of the Baltic, and the northern seas, and is found in some parts of the Mediterranean Vast shoals appear in the British seas during the spring; keeping at the distance of from about half a mile to that of three from the shore: they are caught in vast numbers by the line, and afford excellent diversion. their food consists of small fishes, sea insects, and worms: they are said to be particularly fond of sprats and young herrings, with which the fishermen generally bait for them.

7. *Gadus carbonarius*, or coal-fish, when

full grown, is readily distinguished by its very dark colour, though in this respect it sometimes varies: it is of a moderately long and elegant shape, with a small head, sharpened snout, and lower jaw exceeding the upper in length: when full grown, the head, dorsal fins, tail, and upper parts of the body are of a dusky black, which gradually softens into a silvery tinge as it approaches the abdomen. It is an inhabitant of the Baltic, the northern and Mediterranean seas: it is common on the most of our rocky and deep coasts, but particularly on those of Scotland and the Orkneys.

8. *Gadus merluccius*, or hake, with two dorsal fins. The head is large, broad and flat at the top, but compressed on the sides: the opening of the mouth wide, and the jaws armed with two rows of long, curved teeth, intermixed with smaller ones: the palate is also furnished with a row of teeth on each side; the pectoral and ventral fins are of a moderate size, and the tail is nearly even at the end; the lateral line commences by several small warts beyond the head, and is continued in a straight direction to the tail: the usual length of the hake is from one to two feet.

This fish is an inhabitant of the Mediterranean and northern seas, in both of which its fishery is very considerable: it is salted and dried in the manner of cod, haddock, &c.

9. *Gadus molva*, or the ling, takes its name from its length, being corrupted from the word long; the body is slender; the head flat. The usual size is from three to four feet, but is sometimes seen of the length of seven feet: in colour it varies, being sometimes of an olive hue on the sides and back, and sometimes cinerous: the abdomen is white, as are also the ventral fins, and the dorsal and anal are edged with white: the tail is marked near the end with a transverse black bar, and tipped with white.

The ling is an inhabitant of the northern seas, and forms in many places a considerable article of commerce. Vast quantities of this fish are salted for exportation as well as for home consumption.

10. *Gadus lota*, or the burbot, highly esteemed for its superior delicacy, is an inhabitant of clear lakes and rivers, and is found in many parts of Europe and Asia. In our own country it occurs chiefly in the lakes of the northern counties, but it is said to arrive at its greatest perfection in the lake of Geneva, where it is found in great plenty.

The burbot is considered as a very voracious fish, preying on all the smaller fishes, as well as on frogs, worms, and aquatic insects: the largest of those which are taken in England have been rarely known to exceed the weight of three pounds, but in some parts of Europe they are found of more than double that weight, and of the length of three feet or more.

GÆRTNERE, a genus of the decandria monogynia class and order. There is one species, a shrub of the East Indies.

GAGE, in law-books, the same with surety or pledge.

GAGE, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catches hold under it; then as many feet as the pike is under water, is the ship's gage.

GAGE, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. There are several kinds of these gages, as the flat-gage, the face-gage, and italic-gage, &c.

GAGE, *sliding*, a tool used by mathematical instrument-makers, for measuring and setting off distances. It is also of use in letter-cutting, and making of moulds.

GAGE, *sea*, an instrument invented by Dr Hales, and Dr. Desaguliers, for finding the depth of the sea.

GAHNIA, a genus of the monogynia order, in the hexandria class of plants. There are two species, herbs of New Zealand and Otaheite.

GALANTHUS, the *snow-drop*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. There is but one species, viz. the nivalis; which is a bulbous rooted flowery perennial, rising but a few inches in height, and adorned at top with small tripetalous flowers of a white colour. There are three varieties, viz. the common single-flowered snow-drop, the semi-double snow-drop, and the double snow-drop. They are beautiful little plants, and are much valued on account of their early appearance, often adorning the gardens in January or February, when scarcely any other flower is to be seen.

GALARDIA, a genus of the class and order syngenesia polygamia frustranea. There is one species; an annual of Louisiana.

GALAXIA, a genus of the monodelphia triandria class and order. There are two species, herbs of the Cape.

GALAXY, in astronomy, the via lactea, or milky way, a tract of a whitish colour, and considerable breadth, which runs through a great compass of the heavens, sometimes in a double, but for the most part in a single stream; it is composed of a vast number of stars, too minute or too remote from the earth, to be distinguished by the naked eye; but which are discovered in all parts of it, in great numbers, by the assistance of the telescope.

GALBANUM exudes from the *bubon galbanum*. This juice comes over in masses, composed of white, yellowish, brownish-yellow, and brown tears, unctuous to the touch, softening betwixt the fingers; of a bitterish, somewhat acrid, disagreeable taste, and a very strong smell; generally full of bits of stalks, leaves, seeds, and other foreign matters.

GALEGA, a genus of the class and order diadelphia decandria. There are 19 species, some of them known by the name of goats' rue.

GALENIA, a genus of the digynia order, the octandria class of plants, and in the natural method ranking under the 13th order, succulentæ. There are two species, shrubs of the Cape.

GALENA, in mineralogy, sulphuret of lead, is very common, and is found both in masses and crystallized. The primitive form of its crystals is a cube.

Its colour is commonly blueish grey, like lead, but brighter. Streak blueish grey and metallic. Lustre metallic. Texture foliated

Fragments cubical. Soft; but brittle. Specific gravity 7.22 to 7.587 Effervesces with nitric and muriatic acids. It is composed of from .45 to .83 lead, and from .086 to .16 of sulphur. It generally contains some silver, and sometimes also antimony and zinc.

GALEOPITHECUS. *Colugo.* A genus of quadrupeds. The generic character is front-teeth, in the upper jaw none; in the lower six, short, broad, distant, pectinated; canine-teeth very short, triangular, broad, sharp, serrated; grinders four, truncated, and muricated with conical protuberances; flying-skin surrounding the body, limbs, and tail.

Galeopithecus volans, the flying colugo, is a native of the Molucca and Philippine islands, where it is said to frequent woody places, and to feed principally on fruits. It almost constantly resides on trees, and spreads its membranes, and balances itself to the place it aims at in a gentle manner; but in ascending it uses a leaping pace. The whole length of the animal is about three feet: the breadth, when expanded, nearly the same: the tail is slender and about a span long. The membrane, or expansile skin, by which it is enabled to fly, is continued on each side, from the neck to the fore feet; thence to the hind feet; and again to the tip of the tail. The whole upper side of the animal is generally of a deep ash-colour; and the whole under side, both of the body and membrane, is of a yellowish colour. The head is long; the mouth rather small; the tongue, fleshy, broad, rounded, attenuated on the edges, and ciliated with papillæ. The ears are small, round, membranaceous, and marked internally by numerous semicircular transverse streaks. The legs are clothed with a soft yellow down: there are five toes on each foot, united by a common membrane, and terminating in large, crooked claws. This animal is called by the Indians caguang, colugo, and gigua. It was first described by Bontius in his History of Java.

GALIUM, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellatæ. There are 48 species, of which the most remarkable are, the verum or yellow lady's bed-straw, and the aperine clivers or goose-grass. The former has a firm, erect, brown, square, stem; the leaves generally eight in each whorl, linear, pointed, brittle, and often reflex; branches short, generally two from each joint, terminating in spikes of small yellow flowers. It grows commonly in dry ground and on road-sides. The flowers will coagulate boiling milk; and the best Cheshire cheese is said to be prepared with them.

GALL, in the animal œconomy, the same with bile. See PHYSIOLOGY.

GALL-*bladder*, called vesicula, and cystis fellea, is usually of the shape of a pear, and of the size of a small hen's egg. It is situated in the concave side of the liver, and lies upon the colon, part of which it tinges with its own colour. It is composed of four membranes, or coats: the common coat; a vesicular one; a muscular one, consisting of straight, oblique, and transverse fibres; and a nervous one, of a wrinkled or reticulated surface within, and furnished with an unctuous liquor.

The use of the gall-bladder is to collect the bile, first secreted in the liver, and mixing with its own peculiar produce, to perfect it farther, to retain it together a certain time, and then to expel it.

GALL, in natural history, denotes any protuberance or tumour produced by the puncture of the insects on plants and trees of different kinds. Galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spungy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

GALLATES, are salts formed by the gallic acid with alkaline earths, or with metallic bases.

GALLEON, in naval affairs, a sort of ships employed by Spain in the commerce of the West Indies. The Spaniards sent annually two fleets; the one for Mexico, which they called the flota; and the other for Peru, which they called the galleons

GALLERY, in fortification, a covered walk, across the ditch of a town, made of strong beams, covered over head with planks, and loaded with earth; sometimes it is covered with raw hides to defend it from the artificial fires of the besieged.

GALLERY *of a mine,* is a narrow passage, or branch of a mine carried on under-ground to a work designed to be blown up.

GALLERY, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

GALLEY, in naval affairs, a low-built vessel using both sails and oars, and commonly carrying only a main-mast and foremast, to be struck or lowered at pleasure.

GALLIC *acid.* This acid is found in different vegetable substances possessing astringent properties, but most abundantly in the excrescences termed galls or nut-galls, whence it derives its name. It may be obtained by macerating galls in water, filtering, and suffering the liquor to stand exposed to the air. It will grow mouldy, be covered with a thick glutinous pellicle, abundance of glutinous flocks will fall down, and, in the course of two or three months, the sides of the vessel will appear covered with small yellowish crystals, abundance of which will likewise be found on the under surface of the supernatant pellicle These crystals may be purified by solution in alcohol, and evaporation to dryness. Or muriate of tin may be added to the infusion of galls, till no more precipitate falls down; the excess of oxide of tin remaining in the solution, may then be precipitated by sulphuretted hydrogen gas, and the liquor will yield crystals of gallic acid by evaporation.

A more simple process, however, is that of M. Fiedler. Boil an ounce of powdered galls in sixteen ounces of water to eight, and strain. Dissolve two ounces of alum in water, precipitate the alumina by carbonate of potash; and after edulcorating it completely by repeated ablutions, add it to the decoction, frequently stirring the mixture with a glass rod. The next day filter the mixture; wash the precipitate with warm water, till this will no longer

blacken sulphate of iron; mix the washings with the filtered liquor, evaporate, and the gallic acid will be obtained in fine needled crystals.

The gallic acid is of extensive use in the art of dyeing, as it constitutes one of the principal ingredients in all the shades of black, and is employed to fix or improve several other colours. It is well known as an ingredient in ink.

GALLINÆ, in ornithology, the fifth order of birds. Under this order are comprehended the peacock, pheasant, turkey, the common dunghill cock, partridge, grous, dodo, curissoa, &c

GALLON, a measure of capacity both for dry and liquid articles, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured; for instance, the wine gallon contains 231 cubic inches, and holds eight pounds five ounces and two-thirds avoirdupois, of pure water: the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter avoirdupois, of water: and the gallon for corn, meal, &c. two hundred and sixty eight cubic inches and four fifths, and holds nine pounds eleven ounces and a half of pure water.

GALOPINA, a genus of the tetandria digynia class and order. Cal. none; cor. fourcleft; seeds two, naked. A plant of the Cape.

GALVANISM, or *electro-chemistry*, is the name given to a species of electricity produced by connecting dissimilar metals, by means of an intervening and oxidating fluid. It is termed Galvanism from the circumstance of its having been first observed by Galvani, professor of anatomy at Bologna. This philosopher was fortunate enough to make some observations on the electricity of the muscles of frogs, that to him appeared to depend on a new power in the animal body; and although some of the conclusions which he drew from the discovery are now admitted to be erroneous, yet they led to a train of experiments which have immortalized his name, by connecting it with some of the most brilliant discoveries of modern science.

This grand discovery was made by Galvani in the year 1789, since which time it has employed the attention of several eminent philosophers; but those who have most eminently distinguished themselves on the subject are Valli, Volta, Monro, Fowler, Davy, and Wollaston. Electricity, as produced by friction, has hitherto been but of very limited application in any of the useful arts; but the agency of the Galvanic apparatus has totally changed the face of chemistry, and promises a speedy developement of the hitherto mysterious nature of magnetism.

Many curious and interesting facts resulted from the researches of the above mentioned philosophers; but they are by far too numerous to detail in this place; the most important facts which they establish, may be reduced to the following heads:

First, That the passage of a small quantity of electricity through the nerves of any animal, occasions a tremulous motion or contraction of the contiguous muscles, and sometimes an extension of the limbs. This effect takes place both in living animals, and in such as have been recently killed, and even in detached limbs of these last. The effect is shewn to the greatest advantage on cold-blooded animals, as frogs and fishes, which retain the power of action after death much longer than others.

Secondly, The same effects that are produced by the passage of electricity, also result from the contact of different metals with the nerves and muscles; and the effects are always most considerable when the metals are most essentially different; thus zinc and gold, or zinc and silver, form a very active combination.

Thirdly, By the same means that muscular motion is excited in these trials, some of the senses are remarkably affected, as appears when the experiment is made on living animals.

The following simple and easily performed experiments will demonstrate these facts.

Take a live frog, and paste a piece of tinfoil on its back, and place it on a plate of zinc; form a communication by means of a fine clean copper wire between the zinc and the tinfoil, and spasmodic convulsions will be immediately produced.

Or procure a small flounder; place it in a dish upon a slip of zinc, and lay a shilling, or other silver coin upon its back; then, as in the former case, connect the zinc and silver, and strong muscular contractions will be the result.

The human body, whilst undergoing certain chirurgical operations, or its amputated limbs have been convulsed by the application of metals. But the living animal body may be rendered sensible of the action of metallic application in a harmless way, and both the senses of taste and sight may be affected by it, but in different degrees according to the various constitutions of individuals.

Let a man lay a piece of zinc upon his tongue, and a piece of some other metal, as silver, under the tongue; on forming the communication between these two metals, either by bringing their outer edges in contact, or by the interposition of some other piece of metal, he will perceive a peculiar sensation, accompanied with a sort of cool and subacid taste. The sensation seems to be more distinct when the metals are of the usual temperature of the tongue. The siver or gold may be applied to any other part of the mouth, to the nostrils, to the ear, or to other sensible parts of the body, while the zinc is applied to the tongue; and on making the communication between the two metals, the taste will be perceived upon the tongue. The effect is more remarkable when the zinc touches the tongue in a small part, and the silver in a great portion of its surface. Instead of the tongue, the two metals may also be placed in contact with the roof of the mouth, as far back as possible; and on completing the communication, the irritation will be perceived.

In order to affect the sense of sight by means of metals, let a man in a dark place put a slip of tin-foil upon the bulb of one of his eyes, and a piece of silver in his mouth. On completing the communication between the spoon and the tin-foil, a faint flash of white light will appear. This experiment may be performed in a more convenient manner, by placing a piece of zinc between the upper lip and the gums, as high up as possible, and a silver piece of money

upon the tongue; or else by putting a piece of silver high up in one of the nostrils, and a piece of zinc in contact with the upper part of the tongue; for in either case the flash of light will appear whenever the two metals are made to communicate, either by the immediate contact of their edges, or by the interposition of other good conductors.

It has been long asserted, that when porter is drank out of a pewter pot, it has a taste different from what it has when drank out of glass or earthenware.

It has been observed, that pure mercury retains its metallic splendour during a long time; but its amalgam with any other metal is soon tarnished or oxidated.

The Etruscan inscriptions, engraved upon pure lead, are preserved to this day; whereas some medals of lead and tin, of no great antiquity, are much corroded. Works of metal, whose parts are soldered together by the interposition of other metals, soon tarnish about the places where the different metals are joined.

When the copper sheeting of ships is fastened on by means of iron nails, those nails, but particularly the copper, are readily corroded about the place of contact.

An account of the recent discoveries and experiments of Sir Humphrey Davy, which relate to this subject, will be found under the article **SHEATHING**.

Since Galvani's discoveries, the action arising from the combination of three conductors has been examined with great care, and with considerable success, especially by Mr. Volta, who discovered that the slight effect of such a combination may be increased to a prodigious degree by repeating the combination; for instance, if a combination of silver, zinc, and water, produce a certain effect, a second combination of another piece of silver, another piece of zinc, and another quantity of water added to the first, will increase the effect; the addition of a third combination will increase the effect still more.

The apparatus now in use for Galvanic operations, is commonly termed the Voltaic battery. This instrument is variously constructed; the powers of the original construction were found to be extremely limited, and the use of it is now almost entirely abandoned. On this account we shall here do little more than refer the reader to the engravings of some of the earliest methods of fitting up the Galvanic battery. The simplest form of this instrument is that to which Volta gave the name of "*corronne des tasses.*"

It consists of a row of wine, or other glasses, containing salt and water, or any saline fluid. Into each of these one end of a metallic ore, consisting of a plate of zinc connected by a wire with a plate of copper, is plunged. These ores are so arranged, that the copper extremity of the first is in the same glass with the zinc extremity of the second, the copper of the second with the zinc of the third, and so on in regular order, as exhibited in fig. 1, Plate XVII.

This method, as may be seen by inspection, was extremely incommodious, and could not be constructed on such a scale as to obtain great power. Another method, which approximates much nearer to the power of the modern battery, is represented in fig. 2. This is called the Voltaic or Galvanic pile. It consists of a number of plates of zinc and copper, either round or square, of any size, and of an equal number of pieces of cloth, of the same form, but rather smaller. These last are soaked in salt water, or very dilute muriatic acid, until they are thoroughly moistened. The pile is then thus constructed. Place a plate of copper upon the table, then on that place a plate of zinc, and on the zinc one of the moistened discs of cloth; upon this a second series of copper, zinc, and moistened cloth in the same order; proceed thus until a series of fifty or sixty repetitions have been placed one upon the other, and the pile is complete. If now the operator moisten both his hands with the saline liquid, and with a finger of one hand touch the bottom of the pile, and with a finger of the other the top or upper plate, a slight shock will be felt at every repetition of the contact. The preparation, however, of such a pile, is a very troublesome operation; and its action, even at the strongest, will never suffice for any of the more brilliant experiments in the electro-chemical science.

The most approved and the most powerful form of the battery is that represented in fig. 3. This consists of an oblong trough of dried mahogany, into which any convenient number of double plates of copper and zinc, soldered together, are united in regular order. The intervening cells are nearly filled with the acid solution, and the action produced by connecting the two ends of the arrangement together by clean copper wires.

For the purpose of insulation, the connecting wires are generally passed through two small glass tubes of about six inches long, and which are to be held in the hands of the operator: these are seen in the figure. The ends of these wires that enter the trough, may be made fast by passing them tightly through a small piece of wood firmly fixed into the extreme cells of the trough. The substance to be operated on should be placed upon a plate of strong glass.

In fig. 4, is represented the method generally used for connecting a number of these troughs together when great intensity of action is required: the connection is formed by a slip of copper passing from the last cell of one trough into the first of that which is placed next to it.

In fig. 5, is represented another method of fitting up the trough. Here the trough A is made of earthen ware, having partitions of the same material, and the metallic plates are attached by screws and nuts to a bar of wood, so that they may be immersed and removed at one operation. The troughs are filled with dilute acid, and by uniting them in regular order, the apparatus may be enlarged to any required extent. On this principle, the great apparatus of the Royal Institution is constructed. An important improvement has been suggested in the construction of the Voltaic apparatus by Dr. Wollaston, by which great increase of quantity is obtained without inconvenient augmentation of the size of the plates. This improvement consists in extending the copper plate so as to oppose it to every surface of the zinc, as represented in fig. 6. A is the rod of wood to which the plates are screwed in the usual manner. B B the zinc plates connected as usual with the copper plates C C, which are

doubled over the zinc plates, and opposed to them on both sides, any contact of the surfaces being prevented by pieces of cork or wood placed at D D. Dr. Wollaston, with a single pair of plates constructed on this principle, succeeded in fusing and igniting a fine platinum wire. This is allowed to be the most economical and useful form in which the Voltaic apparatus has yet been constructed.

The reader will now perceive that he may construct his apparatus of any size that is best suited to the nature of the experiments which he has occasion to make. With a trough containing ten pairs of four inch plates, fitted up on the principle last explained, he may safely proceed with the more common experiments; but if he wish great intensity of action, he should never have fewer than from 150 to 200 pairs of such plates in the best possible state of action.

Experience is the best guide with respect to the preparation of the fluid with which the troughs are to be filled; but, in general, from one part of muriatic acid and sixteen parts of water, to one of acid and twenty of water, are found to be the most convenient proportions. The acid and water should be mixed in any large earthenware vessel, and well stirred with a glass rod before the compound is poured into the trough; the cells should be filled to within a quarter of an inch of the top, and the upper edges of the plates wiped perfectly dry with a cloth. It may be necessary to observe that the action is always strongest at the first; in which case the operator should study to apply it in the first instance to those experiments which require the greatest intensity of the Voltaic power.

The most extraordinary phenomena of a Galvanic battery are the chemical effects and the modifications which are produced by it upon the bodies concerned, or upon such as are placed in the circuit. We shall here describe the simplest mode of exhibiting the principal of those phenomena, namely, the evolution of gas from water, from which the mode of conducting similar experiments is easily derived.

A B, fig 7, exhibits a glass tube full of distilled water, and having a cork at each extremity. E F is a brass or copper wire, which proceeds from one extremity of a Galvanic battery, and passing through the cork A, projects within the tube. H G is a similar wire, which proceeds from the other extremity of the battery, and comes with its extremity G within the distance of about an inch or two from the wire F.

In this situation of things, it will be found that bubbles of gas proceed in a constant stream from the surface G of the wire which proceeds from the negative end of the battery; these bubbles of gas, ascending to the upper part of the tube, accumulate by degrees. This gass is the hydrogen, and may be inflamed. At the same time the other wire F deposits a stream of oxide in the form of a cloud, which accumulates in a greenish form in the water, or on the sides of the tube, and is a perfect oxide of the brass. The wire F is discoloured and corroded. If you interrupt the circuit, the production of gas and of oxide ceases immediately. Complete the circuit, and the production of gas re appears.

This production of gas may be observed even where the battery consists of not more than six or eight repetitions of silver, zinc, and water In short, if the power of the battery be sufficient to oxidate one of the wires of communication, the other wire will afford hydrogen gas; both extremities of the wires being in water.

In this experiment it seems, that hydrogen is separated from the water, and is converted into a gaseous state by the wire connected with the negative extremity of the battery: whilst the oxygen unites with, and oxidates the wire connected with the positive end of the battery. If you connect the positive end of the battery with the lower wire of the tube, and the negative with the upper, then the hydrogen proceeds from the upper wire, and the lower wire is oxidated.

If two wires of gold or platinum are used, the stream of gas issues from each, the water is diminished, and the collected gas is found to be a mixture of hydrogen and oxygen. It explodes violently.

In the above described apparatus, a little hole must be made in the lower cork B, for the purpose of giving exit to the water in proportion as the gas is formed.

The deflagration of metallic leaves by the Voltaic energy affords a very pleasing and brilliant display. The best method of performing experiments of this kind is to suspend the leaves to a bent wire, proceeding from one extremity of the battery, and to bring in contact with the lower edge of them a broad metal plate, having its surface polished, and being connected with the opposite extremity. The instant the contact is effected, the deflagration will commence. Gold leaf burns with a vivid white light, tinged with blue, producing a dark brown oxide; silver leaf emits a brilliant emerald green light, and leaves an oxide of a dark grey colour.

If a fine iron wire be connected with one end of a powerful battery, and its end be brought into contact with the surface of some mercury connected with the other extremity of the battery, a vivid combustion both of the wire and the mercury results, and a very brilliant effect is produced. When a fine steel wire of moderate length is interposed in the circuit, it becomes ignited, and may be fused into balls. Small bits of phosphorus, gunpowder, &c. may be readily kindled by a battery of moderate power.

With the large apparatus at the Royal Institution the most striking effects have been produced. When pieces of pointed charcoal, connected with the opposite extremes of the battery, were brought to within the thirtieth or fortieth of an inch of each other, a bright spark was produced, and more than half the volume of charcoal was ignited to whiteness: when the points were withdrawn from each other, a constant discharge took place through the heated air, in a space equal to at least four inches, producing a most brilliant ascending arch of light, broad, and conical in form in the middle When any substance was introduced into this light, it instantly became ignited; platina melted as readily as wax in the flame of a candle; quartz, the spphire, magnesia, lime, all entered into fusion; fragments of diamond, and points of charcoal and plum bago, rapidly

disappeared, and seemed to evaporate in it, even when the connexion was made in an exhausted receiver.

When the poles or extremities of the Voltaic battery are connected by a steel wire, it becomes magnetic; and if by a platinum or other metallic wire, that wire exhibits numerous magnetic poles, which attract and repel the common magnetic needle. This was first discovered by Professor Oersted of Copenhagen. See MAGNETISM.

But by far the most important discovery hitherto made by the application of Galvanism was that of decomposing the alkalis.

The honour of this discovery belongs to Sir H. Davy. He found that a thin piece of potash, or soda, slightly moistened by exposure to the air, and placed between two conductors of platinum, proceeding from the opposite poles of the Voltaic battery, was quickly resolved into a metalline substance highly inflammable, which appeared at the negative surface, and oxygen gas, which was evolved at the positive surface. This new metal will be found described under the article CHEMISTRY. For the information of those who may feel desirous of trying this interesting experiment, it may be proper to remark, that a battery of 100 pairs of three or four inch plates will be found sufficient for the purpose. The apparatus should be excited by a weak acid mixture, of about one part of good muriatic acid to thirty parts of water. A plate of silver or platina being connected with the negative side of the battery, a thin piece of pure potash or soda must be placed upon it, and a platina or silver conductor proceeding from the positive side of the battery, is then to be brought in contact with the upper surface of the alkali, which soon fuses at the points of contact; metallic globules soon appear near the negative surface, and gradually increase in size, until a crust of alkali begins to form on their surface: at this moment they must be removed by the point of a knife, and instantly plunged into naphta. This experiment requires very great care to insure success, which a trifling variation in the power of the battery, the purity of the potash, or the moisture of the atmosphere, may prevent.

Before quitting this subject we would introduce some remarks on the effect of this wonderful agent on the animal system. This, we think, cannot be rendered more intensely interesting than by subjoining the following account of some successfully conducted experiments by Dr. Ure of Glasgow, on the body of a man of the name of Clydesdale, who was executed at Glasgow for murder.

The subject of these experiments, says Dr. Ure, was a middle-sized, athletic, and extremely muscular man, about thirty years of age. He was suspended from the gallows nearly an hour, and made no convulsive struggle after he dropped; while a thief, executed along with him, was violently agitated for a considerable time. He was brought to the anatomical theatre of our university in about ten minutes after he was cut down. His face had a perfectly natural aspect, being neither livid nor tumefied; and there was no dislocation of his neck.

Dr. Jeffray, the distinguished professor of anatomy, having on the preceding day requested me to perform the Galvanic experiments, I sent to his theatre, with this view, next morning, my *minor* Voltaic battery, consisting of 270 pairs of four-inch plates, with wires of communication, and pointed metallic rods with insulating handles, for the more commodious application of the electric power. About five minutes before the police officers arrived with the body, the battery was charged with a dilute nitro-sulphuric acid, which speedily brought it into a state of intense action. The dissections were skilfully executed by Mr. Marshall, under the superintendence of the professor.

Exp. 1. A large incision was made into the nape of the neck, close below the *occiput.* The posterior half of the *atlas vertebra* was then removed by bone forceps, when the spinal marrow was brought into view. A profuse flow of liquid blood gushed from the wound, inundating the floor. A considerable incision was at the same time made in the left hip, through the great gluteal muscle, so as to bring the sciatic nerve into sight; and a small cut was made in the heel. From neither of these did any blood flow. The pointed rod, connected with one end of the battery, was now placed in contact with the spinal marrow, while the other rod was applied to the sciatic nerve. Every muscle of the body was immediately agitated with convulsive movements, resembling a violent shuddering from cold. The left side was most powerfully convulsed at each renewal of the electric contact. On moving the second rod from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain attempted to prevent its extension.

Exp. 2. The left phrenic nerve was now laid bare at the outer edge of the *sternothyroideus* muscle, from three to four inches above the clavicle; the cutaneous incision having been made by the side of the sternocleido mastoideus. Since this nerve is distributed to the diaphragm, and since it communicates with the heart through the eighth pair, it was expected, by transmitting the Galvanic power along it, that the respiratory process would be renewed. Accordingly, a small incision having been made under the cartilage of the seventh rib, the point of the one insulating rod was brought into contact with the great head of the diaphragm, while the other point was applied to the phrenic nerve in the neck. This muscle, the main agent of respiration, was instantly contracted, but with less force than was expected. Satisfied, from ample experience on the living body, that more powerful effects can be produced in Galvanic excitation, by leaving the extreme communicating rods in close contact with the parts to be operated on, while the electric chain or circuit is completed by running the ends of the wires along the top of the plates in the last trough of either pole, the other wire being steadily immersed in the last cell of the opposite pole, I had immediate recourse to this method. The success of it was truly wonderful. Full, nay, laborious breathing, instantly commenced. The chest heaved, and fell; the belly was protruded, and again collapsed, with the relaxing and retiring diaphragm. This process was continued, without interruption, as long as I continued the electric discharges.

In the judgment of many scientific gentlemen who witnessed the scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus. Let it also be remembered, that for full half an hour before this period, the body had been well nigh drained of its blood, and the spinal marrow severely lacerated. No pulsation could be perceived meanwhile at the heart or wrist; but it may be supposed, that but for the evacuation of the blood,—the essential stimulus of that organ,—this phenomenon might also have occurred.

Exp. 3. The supra-orbital nerve was laid bare in the forehead, as it issues through the supra-ciliary *foramen*, in the eyebrow: the one conducting rod being applied to it, and the other to the heel, most extraordinary grimaces were exhibited every time that the electric discharges were made, by running the wire in my hand along the edges of the last trough, from the 220th to the 270th pair of plates: thus fifty shocks, each greater than the preceding one, were given in two seconds. Every muscle in his countenance was simultaneously thrown into fearful action; rage, horror, despair, anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one gentleman fainted.

Exp. 4. The last galvanic experiment consisted in transmitting the electric power from the spinal marrow to the ulnar nerve, as it passes by the internal condyle at the elbow: the fingers now moved nimbly, like those of a violin performer; an assistant, who tried to close the fist, found the hand to open forcibly, in spite of his efforts. When the one rod was applied to a slight incision in the tip of the fore-finger, the fist being previously clenched, that finger extended instantly; and from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life.

About an hour was spent in these operations.

GAMBOGE, is a substance obtained from the stalagmites cambogioides, a tree that grows wild in the East Indies; from which it is had by wounding the shoots. It is brought here in large cakes, which are yellow, opaque and brittle. With water it forms a yellow turbid liquid used in painting. In alcohol it is completely dissolved. If taken internally it operates violently as a cathartic.

GAME, in general, signifies any diversion or sport that is performed with regularity, and restrained to certain rules.

Games are usually distinguished into those of address and those of hazard. To the first belong chess, tennis, billiards, wrestling, &c. and to the latter those performed with cards or dice, as back-gammon, ombre, piquet, whist, &c.

GAMES, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Isthmian, Nemæan, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games.

Among the Romans, there were three sorts of games, viz. sacred, honorary, and ludicrous. The first were instituted immediately in honour of some deity or hero; of which kind were those already mentioned, together with the augustales; florales, palatini, &c. The second class were those exhibited by private persons at their own expence, to please the people; such were the combats of gladiators, the scenic games, and other amphitheatrical sports. The ludicrous games were much of the same nature with the games of exercise and hazard among us: such were the ludus trojanus, tesseræ, tali, trochus, &c.

GAME. It is a maxim of the common law, that goods of which no person can claim any property belong to the king by his prerogative. Hence those animals feræ naturæ, which come under the denomination of game, are styled in our laws his majesty's game; and that which he has he may grant to another; in consequence of which another may prescribe to have the same, within such a precinct or lordship. And hence originated the right of lords of manors or others to the game within their respective liberties.

For the preservation of these species of animals; for the recreation and amusement of persons of fortune, to whom the king, with the advice and assent of parliament, has granted the same; and to prevent persons of inferior rank from misemploying their time, certain acts of parliament have been made. The common people are not injured by these restrictions, no right being taken from them which they ever enjoyed; but privileges are granted to those who have certain qualifications therein mentioned, which before rested solely in the king.

GAMING, the art of playing or practising any game, particularly those of hazard, as cards, dice, tables, &c.

The laws of gaming are founded on the doctrine of chances.

De Moivre, in his treatise De Mensura Sortis, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose p the number of cases in which an event may happen, and q the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as p to q.

If two gamesters, A and B, engage on this footing, that if the cases p happen, A shall win; but if q happen, B shall win, and the stake be a; the chance of A will be $\frac{pa}{p+q}$ and that of B $\frac{qa}{p+q}$; consequently, if they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that if A throw two or more aces at eight throws, he shall win; otherwise B shall win; what is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five where it may not, let $a=1$, and $b=5$. And since there are eight throws of the die, let $n=8$; and you have $\overline{a+b}^n - b^n - nab^{n-1}$, to $b^n + nab^{n-1}$, that is, the chance of A will be to that of B, as 663991 to 10156525, or nearly as 2 to 3.

A and B are engaged at quoits, and after playing some time, A wants 4 and B 6; but B is so much the better gamester, that his chance against A upon a single throw would be as 3

to 2; what is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws: therefore raise $a+b$ to the ninth power, and it will be $a^9 + 9a^8b + 36a^7b^2 + 84a^6b^3 + 126a^5b^4 + 126a^4b^5$, to $84a^3b^6 + 36a^2b^7 + 9ab^8 + b^9$. call a 3, and b 2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at quoits, and A can give B 2 in 3, what is the ratio of their chances at a single throw? Suppose the chances as z to 1, and raise $z+1$ to its cube, which will be $z^3 + 3z^2 + 3z + 1$ Now, since A could give B 2 out of 3, A might undertake to win three throws running; and, consequently the chances in this case will be as z^3 to $3z^2+3z+1$. Hence $z^3 = 3z^2 + 3z + 1$: or, $2z^3 = z^3 + 3z^2 + 3z + 1$. And therefore, $z\sqrt[3]{2} = z + 1$; and consequently, $z = \frac{1}{\sqrt[3]{2}-1}$ The chances, therefore, are $\frac{1}{\sqrt[3]{2}-1}$, and 1, respectively.

Suppose I have two wagers depending, in the first of which I have 3 to 2 *the best of the lay*, and in the second 7 to 4, what is the probability I win both.

1. The probability of winning the first is $\frac{3}{5}$, that is the number of chances I have to win, divided by the number of chances, the probability of winning the second is $\frac{7}{11}$; therefore, multiplying these two fractions together, the product will be $\frac{21}{55}$, which is the probability of winning both. Now, this fraction being subtracted from 1, the remainder is $\frac{34}{55}$, which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$: therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$ the product $\frac{12}{55}$ will be the probability of my winning the first and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability that I do not win the first, and at the same time lose the second

3. If I would know what the probability is of winning the second, and at the same time losing the first, I argue thus: the probability of winning the second is $\frac{7}{11}$, the probability of losing the first is $\frac{2}{5}$: therefore multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{2}{5}$, and the probability of losing the second $\frac{4}{11}$: therefore, the probability of losing them both is $\frac{8}{55}$, which being subtracted from 1, there remains $\frac{47}{55}$: therefore the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration.

GAMMONING, among seamen, denotes several turns of rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT, in music, the name given to the scale laid down by Guido, and to the notes of which he applied the monosyllables *ut, re, mi, fa, sol, la*. Having added a note below the lowest tone of the ancients, he adopted for its sign, the gamma, or third letter of the Greek alphabet; and hence his scale was afterwards called gammut. This gammut consisted of twenty notes, viz two octaves and a major-sixth. The first octave was distinguished by capital letters, as G, A, B, &c. the second by small letters, *g, a, b*, &c. and the supernumerary by double letters, as *gg, aa, bb*, &c. By the word gammut, we now generally understand the whole existing scale: and to learn the names and situations of its different notes is to learn the gammut.

GANG, in sea affairs, a select number of a ship's crew appointed on any particular service, and commanded by an officer suitable to the occasion.

GANG-*board* is a plank with several steps nailed to it, for the convenience of walking into, or out of a boat upon the shore, where the water is not deep enough to float the boat close to the landing place.

GANGRENE. See SURGERY.

GANTLET, or GAUNTLETT, a large kind of glove made of iron, and the fingers covered with small plates. It was formerly worn by cavaliers, when armed at all points.

GANTLOPE, in sea affair [illegible] nounced gantlet, is a race which a criminal is sentenced to run in a vessel of war for felony, or some other heinous offence. The whole ship's crew is disposed in two rows, standing face to face on both sides the deck, each person being furnished with a small twisted cord, having two or three knots in it; the delinquent is then stripped naked above the waist, and obliged to pass forward between the two rows, a certain number of times, rarely exceeding three, during which, every person is enjoined to give him stripes as he runs along: this is called "running the gantlet," and is seldom inflicted but for crimes which excite general antipathy among the seamen.

GAOL *delivery*. By the law of the land, that men might not be long detained in prison, but might receive full and speedy justice, commissions of gaol-delivery are issued out, directed to two of the judges, and the clerk of assize associate; by virtue of which commission, they have power to try every prisoner in the gaol committed for any offence whatsoever.

GARCINIA, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 18th order, bicornes. There are three species. The mangostana is a tree of great elegance, and producing the most pleasant fruit of any yet known.

GARDENIA [illegible] genus of the pentandria monogynia class [illegible] order. There are 15 species, chiefly shrubs of the Cape and Japan. They are known in our stoves by the name of Cape jasmin and some of them are highly ornamental.

GARDENING. This art so natural to man, and so conducive to the comforts and luxuries of life, may properly be divided into two branches; practical, and picturesque or landscape gardening.

A garden, properly speaking, is a small spot of ground attached to the house. As the house is itself a regular and formal object, so we

naturally expect something of the same regularity in this appendage. Neatness too is one of the chief excellencies of a garden, and this is found to be wholly inconsistent with a rage for the picturesque.

The situation of a garden should be dry, but rather low than high, and as much sheltered as can be from the north and east winds. These points of the compass should be guarded against by high and good fences; by a wall of at least ten feet high; lower walls do not answer so well for fruit-trees. A garden should be so situated, that it may be as much warmer as possible than the general temperature of the air is without, or ought to be made warmer by the ring and subdivision fences.

The form of a garden may be a square, [illegible] it can be avoided, because crops come in [illegible] and plants do not stand the winter so well, [illegible] such a situation. A garden with a northern aspect has, however, its advantages, being cooler for some summer productions.

The soil that suits general cultivation best is a loam, rather red than black. The worst soil is a cold heavy clay, and the next a light sand; a moderate clay, however, is better than a light soil, though not so pleasant to work. If the soil is too poor, too strong, or too light, it is to be improved without delay. Let it first be broken and cleaned of all rubbish, to a regular level depth at bottom as well as at top, so as to give full eighteen inches of working mould, if the good soil will admit of it; none that is bad should be thrown up for use. This rule of bottom levelling is particularly necessary when there is clay below, as it will secretly hold up wet, which should not stand in any part of the garden. When a piece of ground is cleared it would be of advantage to have the whole thrown into two-feet wide trenches. There is this advantage of a deep staple, that in the cultivation of it the bottom may be brought to the top every other year, by double trenching; and being thus renewed, less dung will do, and sweeter vegetables be grown.

The aspect of the wall designed for the best fruits may be full south; or rather inclining to the east, by which it will catch the sun's rays at its rise, the cold night-dews be earlier dissipated, and the scorching rays of the afternoon sun are sooner off. By thus having the walls of a garden not directly to the four points, the north wall is greatly advantaged by having more sun.

The border next this wall should be of very good earth, about two feet deep, rising a little towards the wall. A free moderate loam, or some fresh maiden soil, not too light, is necessary to make the borders promising good; and in order to this, if manure is necessary, let it rather be that of rotted vegetables, or turf, with a small quantity of wood-ashes, for the roots of fruit-trees should not meet with much dung, at least of horses: that of cows is the best, or that of sheep or hogs will do well rotted, well mixed, &c. being worked in the borders as long as possible before the trees are to be planted.

If a garden is large and square, a second south wall, running down the middle of it, would be very useful, and so, if large and long, a cross wall or two might be adopted, as giving opportunity for the cultivation of more trained fruit-trees; and if there is any idea of forcing fruits, these intersecting walls, ranging east and west, are [illegible]t (as situated within the ring-fence), [illegible]d with flues, &c.

The best fruit-border [illegible] prepared for peaches, nec[illegible] apricots, or vines and figs, the trees sh[illegible] their residence there (if the leaf is [illegible] about the latter part of October, or as [illegible] as can be. If the middle of Dec[illegible] February is then the time; [illegible] plant all winter, if the weather [illegible] the time to work [illegible]; may do, or even [illegible] not be older than two [illegible] budding except in fine [illegible] early and late peaches; [illegible] cut off, and the latter not [illegible] plant should be about 12 [illegible] the wall; and let apricots, peaches, and nectarines, be twenty feet asunder, more or less, according to the height of the wall; though for the small early sorts fifteen or sixteen feet will do. As the larger apricots, however, grow freely, and do not well endure the knife, they ought to have twenty-five feet allowed them. This is for a wall of nine or ten feet high; if higher, the distance may be less, and if lower, the contrary. Fig-trees require as much room as the apricot, or rather more; as they grow freely, and are to extend without shortening. Though other trees are best planted in October, the fig should not be till March.

The intermediate spaces between peaches, nectarines, and apricots, may have a vine, a dwarf cherry, or currant or gooseberry tree of the early sorts, as the smooth green and small red, to come in early. But wherever grapes can be expected to ripen, there let a young plant, or cutting, be set, though the space should be confined; for the vine, freely as it shoots, bears the knife well to keep it within bounds. If the wall is high, the cherry or plum may be half-standards; which being after a while kept above, will be more out of the way of the principal trees: though dwarfs may be trained so as not to interfere. Some have planted half-standards of the same kind of fruit as the dwarfs; but which ever mode is adopted, let the intermediate trees be pruned away below in good time, in order to accommodate the principals freely as they mount and extend.

Plums, cherries, and pears, may occupy the other walls; the two former at about fifteen feet, or it may be twenty feet asunder. Cherries, except the murella, will not do well in a full north aspect; but any sort of plum (rather a late one) and summer pears, and also nut-trees, will, if you choose to train them. There should always be some currants and gooseberries in an east and north situation, at the distance of eight feet, where they will be easily matted, when ripe, to come in late, as October, November, or perhaps December. Pear-trees of free growth are hardly to be kept within tolerable compass on low walls; but [illegible] tempted, should have at least th[illegible] them. The best sorts of winte[illegible] a southerly wall to ripen them [illegible] prove them in size and flavour. The ga[illegible]

of a house is well adapted for a pear-tree, as it affords room, which they require. Apples may do on a wall (and if any on a good wall, let it be the golden pippin,) yet the practice is seldom adopted. For furnishing walls choose trees of moderate wood, young, well rooted, clean, and healthy.

When the planting of a garden is finished, it is a good way to have a plan of it taken, with the name of every peculiar tree marked on it in their place, to be assured of the sorts when they come to bear.

Here it may be observed, that if any evergreen hedges are desired, in or about, the garden, yew, box, alaternus, [illegible] phillyrea, and pyracantha, may be [illegible] in form, if so desired; in [illegible] a few roses were inter[illegible] fine effect. A deciduous [illegible] or screen, &c. may be made [illegible] setting the larger plants at [illegible] and a smaller one between. [illegible] fence, or sub-division, may be quickly [illegible] of elder cuttings, stuck in at two feet asunder, which may be kept cut within bounds.

A wide border next the south wall, as was said, is best for the trees; and moreover for the many uses that may be made of it for the smaller early, or late tender esculents, and a few early cauliflowers. For the sake of a pleasant warm walk in spring, to have the south border narrow may be desirable; but on no account let it be less than six feet. Take care that this walk is not sunk too much; and that it have a bottom of good earth, as deep as where the trees are planted. Let the body of gravel be thin, and then the roots of the trees will be admitted to run properly under the walk, and find wholesome nourishment; where, if they were stopped by rubbish, they would be apt to canker and disease the trees.

The number and breadth of the walks must in a measure be determined by the quantity of allotted ground; exceeding in these particulars where there is room. But few and wide walks are better than many and contracted.

If the ground is laid out in autumn, defer the making of the walks till spring, when the earth will be settled. Gravel laid towards winter would be disturbed by the frost, and the necessary work about the quarters and borders. But whenever made, the garden ought to be brought to an exact level, or slope; then the walks should be stumpt, keeping the tops of the stumps very level (as guides) to the true pitch of the quarters by a light line, made of good hemp, that will bear pulling tight. Proceed to take the earth out of the alleys about eight inches deep, which may be thrown towards the middle of the quarters, to give them a small convexity, which makes them look well.

Rake the bottom of the walk level, and lay the gravel to within two inches of the top of the stumps. The gravel will settle a little, but the walks should always be about three or four inches at their edge, below the quarters, or these will have a flat, and also a mean appearance.

If edgings are to be made, in order to separate between the earth and gravel, especially if of stone, or wood, or box, they should be done first, and they will be a good rule to lay the box by.

If you have plenty of gravel, lay it moderately fine; if little, some small stones, or rubbish of any kind, may be laid in first, and rammed down level with a broad rammer; but do not spare for a little expence, if gravel can be had, as a thick coat of fine gravel will bear relaying, or turning over, to refresh it occasionally in the spring. As the gravel is laid, let the operator neatly rake the larger parts down to the bottom, leaving a fine surface, in a small degree convex, *i. e.* just barely sufficient to throw off wet; walks that lie very high in the middle are unpleasant to both eye and feet, and cannot be so well rolled and kept in order.

When deep walks of gravel are designed, for the sake of the mould dug out of the alleys it should be foreborne, and laid thin, if any trees are intended to be planted near the edge: for if the roots of trees have not a good soil to strike into, when they reach the walks, they will not prosper. In laying gravel very thick it is a good way to do it at two courses; the first of which may be rough, as it comes from the pit, yet still raking the larger parts down and then ramming or treading it; and the last course should be all of screened materials.

It is best to lay a few yards of gravel only at a time, before ramming or treading; after which it may be necessary to go over it with a fine iron rake, tooth and back; and then a whole walk being finished, it should be repeatedly pressed with a moderately heavy roller; and again soon after the next rain that falls. Thus will the walks become nicely level and firm, in which their excellence consists.

Grass walks may answer where gravel is scarce; but the latter is in all respects preferable.

Camomile has been used also to form green or carpet walks, planting it in sets about nine or ten inches asunder; which naturally spreading the runners are fixed by walking on them, or rolling.

Sand may be adopted for walks, and there is a binding sort of it that does very well; but lay not any of it too thick, as it is the less firm for it. Drift sand is a good substitute for gravel.

Coal-ashes strewed thinly in the alleys are better than nothing, as they at least serve to keep the feet dry and clean. Sea-shells make very good walks.

All trees designed to be planted are to be thought of before winter. Those of the wall have been spoken of; and as to standards, they must have a fair depth of good soil to grow in; for it should be remembered, that tree-roots in a garden are prevented from running over the surface, as they do in an undisturbed orchard. It is necessary that some caution should be used not to dig the ground too near and too deep about garden trees lest loosening the roots they should not be able to stand the wind; and because the nearer the surface any root grows, the more and choicer fruit the tree bears.

But the fewer standard trees in a garden the better, as they take up much room, and by their shade prevent the proper growth of vegetables that are near them; so that if a garden is small, there should be no trees except those of the wall. The case is different where there is ample room; and the blossoms of fruit-trees (apples particularly) are so delightful, that if they produced nothing for the palate, there

would be a sufficient inducement to plant them for ornament; but let them be dwarf standards in preference to espaliers.

Dwarf-standards occasion less trouble to keep them in order than espaliers, and are generally more productive; for espalier trees are seldom managed well, and thus appear unsightly: at best they are stiff and formal, and obstruct the sight in viewing the quarters of a garden, which, if in order, are worthy of coming under the eye.

If espaliers are planted, let them be only fruit of the best sorts, and in spacious gardens, where they may have a good length and height allowed them to grow freely.

Espalier trees should rather be trained to sawed materials properly framed together, smoothed, and painted. But for a year or two they may be fastened to light stakes, when they will have formed a head, to begin to train them for bearing in the neat manner proposed, that is, to slips of deal joined to light oak posts, as trellises. Whether the slips are placed perpendicularly, or longitudinally, seems indifferent. If the longitudinal mode of training be approved, strong iron wire may be recommended to run through the posts instead of slips of wood, as it shades less, and is stronger and neater. If upright slips are used, they should be slender, and from six to eight inches distance, according to the greater or less freedom of the natural growth of the tree.

Apples should be allowed 24 feet, and pears 30; except those grafted on paradise or quince stocks, for which little more than half this distance may answer. Cherries and plums should have about 18 or 20 feet allowed them. Quinces, medlars, mulberries, and filberts, may also be espaliered. The trees should be planted about a yard from the edge, but farther off is better, if the walks lie deep of gravel or poor materials.

Currants, gooseberries, and raspberries, do well espaliered, as to a production of early and fine fruit.

Trees of a more humble nature, and shrubs, next occupy attention in furnishing a garden. Currants and gooseberries (as bushes) should be planted three feet from the edge, and fully six feet asunder. Some of these very useful shrubs should grow in every aspect of the garden, in order to have a succession of their fruits as long as may be. Those who choose to plant whole quarters of currants and gooseberries ought to do it at six feet asunder in the rows, and the rows eight feet from one another.

Raspberries may be set in plantations, in rows, five feet asunder, allowing three feet between the plants. These shrubs are always best by themselves, as otherwise their suckers over-run the quarters. Between rows of raspberries planted at the above distance, coleworts, early cabbages, cauliflowers, and lettuces, may be set, or spinach sowed in drills; the raspberries having had their pruning and dressing early in autumn, for the purpose. Every year a little short manure, dug in close about the roots, (and deeper as the plantation gets older) will insure fine fruit. Raspberries are not very nice as to soil and situation. The smooth-wooded, or cane rasp, is to be preferred for a principal crop. The large, white, or Antwerp, is also good.

Strawberries may be planted at the edges of borders and quarters, either in single or double rows (rather the latter) for the convenience of gathering, and for ornament; but the common and best way is, in four-feet beds, with eighteen-inch or two-feet alleys, on which beds may be five rows of the wood and alpine, four of the scarlet and pine-apple, three of the Carolina, and two of the Chili; setting the plants at the same distance in the rows, as the rows are from one another in what is called the quincunx order. In a good, cool, loamy soil, which suits them best, a little more distance may be allowed the first four sorts; and in a quite dry light soil, somewhat less, that they may shade one another the better from drought.

The best situation for strawberries is an open and sunny one, as thus they bear more, and finer-flavoured fruit. Some of the scarlets should be planted under warm walls to come early. The woods bear shade as natural to them, and the alpines do tolerably well in it.

The most proper time for planting the strawberry is the first moist weather in September, (or even earlier) that they may be established in the ground before winter, and they will bear the better the first year. Frost is apt to throw up late-planted ones, and injures, if not destroys them. Those planted in spring often suffer from drought, and bear very little the first year, except the alpines. Choose forward runners for planting, and let them be from beds in full bearing, that is, of two or three years old: for plants from old beds are not so fruitful. Press the mould to the roots, give them a watering, and again once or twice, if the weather proves dry. Some gardeners let them run over the beds, which in a dry light soil may be proper; but in this case, a greater distance should be allowed them at planting.

If the alpine sort is planted on a warm border, 18 inches asunder, and suffered to spread, the first runners will fruit the same year, and sometimes this prolific strawberry bears till November.

Fresh plantations of strawberries should be made every fourth year, though in a good soil and with good management they will continue longer: so that where they are suffered to run, the plants being frequently renewed, and old ones removed, beds have borne tolerably for ten years.

The watering of strawberries should not be neglected, doing it almost daily when in flower, and setting their fruit, if the weather proves dry, particularly to those under a warm wall; but this is not to be continued when the fruit is nearly ripe.

Flowering shrubs may be dispersed about, and herbaceous perennial flowers; but plant them not too near the edge, lest they hang over the walks. The bulbous sorts may, however, be within six inches, especially crocusses and snowdrops.

Asparagus and artichokes take up much room, and in small gardens should be left out. It will be of little use to have less than 50 or 60 feet of asparagus beds, as there would be so few heads to cut at a time; and artichokes must be planted wide, or they will not grow large and fleshy, in which their merit consists.

Let not pot-herbs be forgotten, but provide a general herbary in that part of the garden which is warmest, and best shaded, for these are tender plants.

Having spoken of stationary things, the routine of the seasons must dictate the rest; and the inclinations of [illegible] will refresh the memory to take [illegible] providing the most necessary and [illegible] lents for dressing, [illegible] raw salad [illegible] mentioned; but [illegible] and biennials [illegible] conveniently [illegible] be, as much as [illegible] mented.

[illegible] ng a garden with shrubs and [illegible] spect should be had to their usual [illegible] ir bulk, colour, and season, that the [illegible] may be properly varied, harmonious to the eye, and come in regular succession. The latter part of the year is seldom provided for so well as it might be; late flowers should be set in warm situations, as their proper place. In the most dreary months, by judicious planting, evergreens in their neat and cheerful "winter liveries," may be viewed from our windows, and serve instead of flowers.

Those who ga[illegible] a large scale, should take care to h[illegible] ng proper and convenient liber[illegible]. Let there be a [illegible] hot-beds, with some [illegible] and (if dry) for keeping [illegible] eds and herbs. Those also who [illegible] upon a small scale will do well to [illegible] needful implement.

If water can be introduced, and kept clean with verdant banks around it, it would be found very useful where a garden is large; but let it be as near the centre as possible, as the most convenient situation. It should be fed from a pond in preference to a spring.

Mixed gardening, as comprehending the useful with the sweet, the profitable with the pleasant, has been the subject hitherto; but if the flower garden and the kitchen garden are to be distinct, the case is altered; not so much indeed but that still the kitchen garden should be adorned with a sprinkling of the more ordinary decorations, to skirt the quarters, chiefly those of the most powerful sweet scents, as roses, sweet-briars, and honey-suckles, wall-flowers, stocks, pinks, minionet, &c. in order to counteract the coarser effluvia of vegetables, or of dead leaves, which, however, should not be suffered to annoy.

The flower garden, properly so called, should be rather small than large; and if a separate portion of ground is appropriated for this, only the choicest flowers should be introduced, and no trouble spared to cultivate them in the best manner. The beds of this garden should be narrow, and consequently the walks numerous; and not more than one-half or two-thirds the width of the beds, except one principal walk, all round, which may be a little wider. The gravel, or whatever the walks are made of, should lie about four inches below the edge. The beds for tulips, hyacinths, anemonies, ranunculuses, &c. may be three and a half or four feet wide, and those for single flowers the same, or only two and a half feet wide in the borders. Let the beds lie rather rounded in the middle, but the walks flat.

Figured parterres are now out of fashion, as a taste for open and extensive gardening has prevailed; but when the beds are not too fanciful, but regular in their shapes, and chiefly at right angles, after the Chinese manner, an assemblage of all sorts of flowers, in a fancy spot of about sixty feet square, is a delightful home source of pleasure, worthy of [illegible]. There should be neat edgings of box to [illegible] beds, or rather of neat inch-boards, painted lead colour, to keep up the mould. Be sure to keep the box from the very first, as soon as rooted, and always after, as low as possible: clip it twice a year, April and July.

Landscape, or *picturesque gardening*, is so much the work of fancy, and so much depends upon the situation, or what the celebrated Mr. Brown used to call the capability of the place, that no precise rules can be laid down concerning it. All, therefore, that can be expected, is a few loose hints, on which the man of taste may improve according to circumstances.

The pleasure we seek in laying out gardens, is now justly founded upon the principles of concealed art, which appears like nature; but still, whether ingenious contrivances, and decorations, (altogether artificial,) should be so entirely laid aside as they are, may deserve to be considered. Gardens were formerly loaded with statues, and great improprieties were committed in placing them, as Neptune in a grove, and Vulcan at a fountain, large figures in small gardens, and small in large, &c. but perhaps the works of the statuary might still be introduced if well executed, and in proper places. A terrace, as a boundary, is now seldom formed; but in some situations, such an eminence might in several respects be agreeable.

If trees are planted injudiciously, the error is a trifle; but if cut down so, the consequence is serious, and has often been sorely lamented; extirpation should therefore be well thought of before it is executed; especially trees about houses, for many dwellings have been thus too hastily exposed, and deprived of comfortable shelter and shade.

Hilly spots that are in view of the house should be planted with firs, as fine-looking trees, and very hardy. Beech does well on high ground, especially if chalky. In low ground, not to mention alders, and that tribe, the birch, and even the oak, should not be forgotten, where the wet does not long stand.

About the house some shady walks ought always to be provided, by thick planting, if not of trees, yet of flowering shrubs, and evergreens, of which the laurel will be found the most useful.

Those who have much space of ground to decorate, do well to plant trees and shrubs of every kind, as enlarging the *sources* of amusement, and affording [illegible] nities for observation; but if the [illegible] of ground for this purpose is con[illegible], of course, those only should be [illegible] which by their neat foliage, natural [illegible] gay flowers, may be truly estee[illegible].

The walks should [illegible] wide, some inclining to serpen[illegible] as much as possible upon a level. That they may be extensive, they should skirt the grounds, and seldom go across them. In small pleasure-grounds the edges of the walks should be regularly planted with flowers, and long ones occasionally so, or with the most dwarf shrubs; and neat sheltered compartments of flowers, (every now and then to be met with) have a

good effect. If the walks are extended to distant plantations of forest-trees, every opportunity should be taken to introduce something of the herbaceous flowery kind, which will prove the more pleasing, as found in unexpected situations. The outer walks of pleasure-grounds and plantations should every now and then break into open views of the country, and to parts of the internal space, made pleasing, if not striking, by some work of art, or decoration of nature.

Water should only be introduced where it will run itself clear, or may be easily kept so, as also in full sight; and some fall of it should be contrived, (if possible) for the sake of giving it motion and sound, because a lively scene of this element is always much more pleasant than a dead one. Near some pieces of water, as a cool retreat, it is desirable that there should be something of the summer-house kind, as a simple rustic arbour, embowered with the woodbine, sweetbriar, the jessamine, and the rose.

Before the design of a rural and extensive garden is put in execution, it ought to be considered, or anticipated, what it will be in twenty or thirty years time; for it often happens, that a design which looks handsome when first planted, and in good proportion, becomes so small and ridiculous in process of time, that there is a necessity either to alter it, or destroy it entirely, and so plant it anew.

Landscape gardening depends much on the form of the ground, and therefore to shape that is the first object.

Too much plane is to be guarded against; and when it abounds, the eye should be relieved by clumps, or some other agreeable object. Hollows are not easily filled; and eminences mostly are advantageous, in the formation of picturesque scenes, in which the general principle of ornamental gardening consists.

To plant picturesquely, a knowledge of the characteristic differences of trees and shrubs, is evidently a principal qualification.

To range the shrubs and small trees, so that they mutually set off the beauties, and conceal the blemishes of each other; to aim at no effects which depend on a nicety for their success, and which the soil, the exposure, or the season of the day, may destroy; to attend more to the groupes than to the individuals; and to consider the whole as a plantation, not as a collection of plants; are the best general rules which can be given concerning them.

The cultivation of a garden.—The first object with a view to produce should be, to keep the ground in such a state as will enable it to produce good crops. Good vegetables cannot be had without good manure. Yet raw unwrought dung is not good for a garden. The most economical plan therefore, that can be pursued, is for the first year to make good hot-beds of manure, and spread it out upon the quarters, and dig it in autumn and winter. You by this means have a double produce, and the manure is the better.

Dung, however, used in great quantities, and lying in lumps, breeds worms, grubs, and other insects, and causes plants to grow rank-flavoured. Carrots it cankers, and it disagrees with many things. On these accounts some persons have been induced to dress their gardens only with rich fresh earth; which, if they do not overcrop, will do very well.

In the occupation of ground, the change of crops will be proper, as each sort of plant draws a somewhat different nourishment: so that after a full crop of one thing, one of another kind may often be immediately sown; but it should be contrived that a wide crop may follow a close one, and contrariwise.

Close crops, as onions, leeks, carrots, &c. are conveniently and neatly cultivated in beds of from four to five feet width, with alleys of from a foot to eighteen inches between them.

The seasons proper for furnishing the ground with every particular vegetable, should be well attended to, that each may be obtained as early as its nature will permit; and of the seeds and plants used, care must be taken to procure the best of the kind, lest after all the trouble of cultivation, disappointment as to quality should ensue.

Seeds and plants should be adapted, as much as possible, to the soil and situation which best suits them.

The thinning of seedling corps should be done in time, before the young plants have drawn one another up too much. All plants grow stronger, and ripen better, when the air circulates freely round them, and the sun is not prevented from an immediate influence.

Shading of newly-planted things, particularly flowers, is of much benefit, and that in proportion as the season is sunny.

Strawberries and cauliflowers are generally watered in a dry season: that is, the strawberries, when in bloom, in order to set the fruit, and the cauliflowers, when they shew fruit, in order to swell the head. In a light soil, this ought particularly to be done. In very dry weather, asparagus seedlings, early turnips, carrots, radishes, and small salads, will need watering. Slips, cuttings, and layers of any kind, will need water. Pots of flowers must have it frequently.

When watering is undertaken, let it be a complete business; i. e. to the bottom and extent of the roots, as much as may be. The wetting only the surface of the ground is of little use, and in some cases proves detrimental.

Watering the roots of wall-trees, (if dry weather) when the fruit is setting, is by some thought necessary. To young trees only it can however be of use, for the roots of old ones run far and wide; and it is the small fibres of these distant roots, on which the tree chiefly depends for food. Vines should have no water till they are off blossom, (July) and the fruit as big as large pins' heads; and then if the season is very hot and dry, watering the roots twice a week will help the fruit to swell.

As watering is apt to make ground hide-bound and unsightly, let the surface be occasionally stirred and raked, which will make future waterings enter the ground the better.

The quality of water used for refreshing plants is a material thing. Rain water is by far the best, as appears by the verdure and vivacity it gives.

Pond water is next in fitness, and river water follows. Well water is of least account, though local circumstances occasion its use, the

moist. Pump-water, if used directly, is so cold in summer, that it is found prejudicial to plants: and great cold so contracts their vessels, that they perform their proper offices with difficulty, and become diseased.

The management of a garden, as somewhat distinct from the cultivation of it, is an object of consequence; that is, to keep it in such order, that it may not fail in those general impressions of pleasure it is capable of affording, when things are shewn in their best manner. A garden may be cultivated so as to be profitable; and yet not conducted so as to be agreeable to walk in, which in a private garden is a circumstance to be lamented. The proper appearance of a well managed one is expressed by the word neat. Let all be done that can be in order to it.

To be neat, weeding must be industriously followed up, and all litter that is made in working, quickly carried off. The ground also should be frequently stirred and raked between crops, and about the borders, to give all a fresh appearance. There is a pleasantness to the eye in new broken earth: and when there are no flowers left in the borders, this gives an air of culture, and is always agreeable. An asparagus-fork is expeditious and useful in this case: but it must be slightly used, lest it disturb the roots of plants too much. Vegetables should not be suffered to rock themselves by wind, so as to form holes round their stems, but be well earthed up or otherwise supported.

Trees and shrubs should be constantly freed from suckers and dangling shoots, and wall trees ought to be regularly kept in order. Grass-plats and walks should have their edges occasionally cut, and be mowed as often as there is the least hold for the scythe, for they lose much of their beauty, when the grass gets long; leaves should not be suffered to remain on them, as it stains the grass, and worm-casts should be cleared away. Edgings of all sorts should be kept in good order, as having a singularly neat effect in the appearance of a garden.

Some fruits may need support, by tying their weak branches, when they get heavy, to stakes, &c. Rows of raspberries and beans are kept neatly up in their lines, by putting in here and there a stake, and using pack-thread lengthwise; and thus will they bear better, and be more conveniently gathered. Strawberries of fine heavy sorts, will be preserved from getting dirty and rotten, by tying their stems to little sticks: by this practice the fruit also gets better ripened, and of a finer flavour. Some persons lay tiles, or moss round the plants, when the fruit is half grown; but this is not, generally, so well, only it has the advantage in keeping the ground cooler in a hot season. The first and finest scarlets best deserve this trouble.

Flowers should be frequently tied up, and dead and dangling parts trimmed off. Some of them cannot do without support; and many sorts are made more secure and beautiful by proper ties.

The sticks used for flowers, should be of smooth wood, as neat painted slips of deal, with or without an ornamental head; white is the best colour, on account of its contrast with the leaves. Decaying flowers should be timely trimmed or removed, and perennials should be regulary freed from the parts running to seed, (except so much as may be wanted) as the production of seeds weakens the root much.

Of Propagation.—Plants are propagated by seeds, suckers, slips, off-sets, divisions, cuttings, layers, and grafts.

By seed is the most general method of propagation, and plants raised any other way are seldom so fine. Those plants from seed which have never been removed, are commonly handsomer, and come forwarder, than those that have been transplanted, provided they were sown in a proper soil and situation.

Commonly speaking, new seed is to be preferred to old, as growing the more luxuriantly, and coming up the surer and quicker.

If old seed is knowingly sown, some allowance in point of time must be made. Peas and beans of two years old, are by some preferred to new, as not running so much to straw.

As to the age of seeds, at which they may be sown and germinate, it is uncertain, and very much depends on how they are preserved.

Seeds should be saved from fine forward plants, secured from rocking about when they get tall; guard them against birds, gather them regularly as they ripen, and keep them dry: curious flower-seeds are kept well in phials: others in small drawers, and some may be hung up, or kept on shelves in their pods.

Seeds may be forwarded for sowing by various ways of procuring a germination before they are put into the ground. In summer it has been usual to steep both broad and kidney beans in soft water, about twenty-four hours, to forward their growth, and to ascertain their vitality.

The smaller seeds, as carrots, &c. may be prepared for sowing, by simply mixing them in a little moist sand, or fine earth, taking care that they do not lie longer than the usual time of their beginning to sprout.

The season for committing seeds to the ground, should be as early as the nature of the plant to be cultivated will bear; for the forward productions which come without forcing are the best as to size, flavour, and fruitfulness, if they meet with no material check from weather.

Let this direction for early sowing be understood, not only of spring, but autumn crops; that the plants designed for winter use, or to stand for spring, may be [illegible] and well established in the ground: t[illegible] for those designed for spring, it is advisable to have two or three different sowings.

To be sure of a crop, and in some things a succession of crops, various sowings should be made through the year, at all times that are not too unnatural as to season; for it is an object in gardening, not only to have early and late productions, but never to be without what may be produced.

Sowings should be generally performed on fresh dug or stirred ground. The digging should therefore be done as near the time designed to sow as can be. If the ground turns up raw, or

wet as early in the spring it is apt to do, a little time must be allowed it to dry, and so also, if rain falls first.

The proper depth at which seeds should be sown is to be carefully observed; if too deep, they will either rot, or not thrive well; and if too shallow, they are liable to be injuriously affected by frost, wind, drought, or birds: but of the two rather too shallow, than too deep, is best.

The smaller the seed the finer should the soil be, and the less also the covering; so that while some, as the seed of celery, is to be but barely covered, others, as pease and beans, may have a depth of two, three, or four inches. But some regard is to be had to the season and soil; in a warm season, and light soil, sow deeper, and the contrary shallower.

The quantity of seed sown is a thing to be attended to with some exactness. Small seeds go a great way, and require a careful hand to distribute them; for though sowing a little too much is a trifle as to the value of seeds, yet to have them come up crowding thick is an evil.

It is not generally advisable to sow several sorts of seed on the same spot, as some persons are accustomed to do.

Some little things of this sort, indeed, may be done; as a piece of ground newly planted with horse-radish may be top-cropped with radishes, or spinach, &c. A thin crop of onions upon new asparagus-beds, may also take place, drawing them while young from about the plants.

All seeds come up best when moderately pressed with the earth; for if they lie too lightly in contact with it, cold and drought more easily affect them; and when once seeds begin to germinate, they are impatient of both. To trample seeds is, on the whole, better than any other pressure. This done, lay all immediately and neatly level with a wide rake, drawing off stones, &c. but do it lightly, to avoid driving the teeth of the rake, which would remove the seed, and make it come up irregularly.

Propagation by suckers is a mode of culture rather peculiar to trees and shrubs. The things to be observed in this business are, to take them up with some care from the mother plant, so as not to injure its root, nor the sucker's own root, by pulling it up without properly loosening it first. The earth should be moved aside by a trowel, and then the sucker cut off by a knife, and not with a spade. Wherever a root appears barked, the part below should be cut off. If it is desired to succeed well, in propagating by suckers, consider that all young roots are tender: let them be trimmed to form, and planted immediately. Suckers with poor roots, must have their heads reduced the more.

Propagation by slips is of two sorts, either from the root or stem. When from the roots, if the whole is not taken up, move the earth carefully aside, and slip it off by a pressure of the thumb and finger, and be cautious of hurting the fibres of the slips, planting with fine and good mould about them. Take off slips from the stem carefully by the push of the thumb, and not too many from the same plant, as it is apt to injure the place by tearing off some of the wood.

Offset is a term sometimes applied to slips from fibrous roots: but more properly so from bulbous roots, which put forth many offsets. These are slipped away at the time they are taken up for removal or replanting, and commonly take two or three years before they bear flowers: dispose of them, therefore, in a nursery, where they may remain undisturbed till they come to a flowering state.

Division of the roots is a way of propagating many sorts of plants. To this end, of course they must be taken up, and then either carefully pulled, or cut asunder with a sharp instrument, as the case may require. It is not safe, however, to divide such roots into very small pieces. The general season for thus splitting fibrous rooted plants is October, but it may be done early in the spring, as February.

Cuttings of a variety of woody plants will grow, and many trees and shrubs are propagated this way; but their sap must be of a watery nature, as those plants that are gummy will not strike (or rarely) though ever so much care is bestowed, or time allowed them. The texture of the wood of cuttings must be somewhat soft, as hard-wooded ones will not grow.

The season for setting slips and cuttings is for some things summer, as wall-flowers and myrtles; and for most from October to March; but, in general, the sooner the better. It has however been said that spring is the best time for all, and that the sap should be in motion first.

Cuttings should be of well-ripened wood, and have the earth pressed to them the whole length they are in the ground; *i. e.* from four to six inches. Cut them with a sharp knife slopewise, and plant in a good soil, and in a situation where they have only the morning sun; and keep them cool (not wet) by occasional watering in dry weather.

Laying of branches is a mode of propagation that may be adopted for almost all forest-trees, and several sorts of fruit-trees and shrubs; *i. e.* all that will grow from cuttings, and many that will not. Layers are made of the lower branches of the plant, and must be young and pliable, to bend down without breaking to the depth of four, five, or six inches in the ground, as the soil is light or heavy, at which they must be held securely by good pegs.

Let the ground about layers be kept cool by occasional waterings, and laying some moss, turf, litter, or rather small pebbles about them, which will not harbour insects. The part out of ground may be supported erectly by a tie to a stick. It is a good way to slit with a sharp knife, the part at the peg, as in carnation layers, a little more than an inch; and some prick a few holes about the part, at a joint, with a blunt awl, to help the layer to strike root. Generally, layers should be shortened to six or eight inches above the ground; or do it to two eyes, be it more or less above ground.

Where there are no branches low enough to be brought into the ground, and it is not thought good to head down for the production of low shoots or suckers, plants may be layered by fixing a broken pot, or a box, with a slit in the side, to the height necessary to lay in a branch. A branch also, if long enough, may be thrust through the hole of a garden-pot upwards, then filled with earth, and supported by some con-

oil with which the cistern is filled to the height of the dotted line, the dipping of the pipe forms a lock by which the return of the gas is prevented. The cistern is formed either of cast iron or lead. F F F F, are the refrigeratory pipes, all connected with the condensing cistern, and connected two and two together at the top by a square box Z, by which the communication between each pair of pipes is formed. Between the first and second, and the third and fourth pipes, are divisions *g g*, crossing the whole width of the cistern, and dipping two or three inches into the oil, forming distinct compartments, by means of which the connection between the first and second pipe is broken off at the bottom, while it is maintained at the top by the square box Z; and the space between the second and third pipe is thus open at bottom, and again between the third and fourth at the top. Hence it is obvious that the gas will travel in the direction of the arrows, and escape from the condenser by the small bent pipe H H H, into the gasometer K K. These pipes may be made of cast iron, lead, or even of strong sheet iron, provided the joints are well made. The gasometer, as represented in the figure, is made of sheet iron, the plates being well rivetted together, and the joinings rendered air-tight by cement. It is suspended by a strong iron chain which works over the pullies, *p p*, and dips into a large tank or reservoir of water W W, and being nicely balanced by the weights R, it will rise in the water as the gas enters, and sink as it escapes by the pipe Y. From the construction of the gasometer, and the method of its suspension, it will appear on inspection, that any requisite degree of pressure for urging the gas along the pipes to the burners may be afforded, by diminishing the number of the moveable weights at R.

L L is the furnace enclosed in an arch of fire brick, on the top of which the retort is placed in the oven M M, the flames passing in the direction of the arrows through the small flame holes, and there, on account of its width, the flames travelling slowly, the whole of the arch, together with the retort, soon become of a red heat, and may be kept at any temperature required by means of a damper placed in the flue N, which leads to the common chimney. O represents the ash-pit of the furnace. Fig. 2. is a transverse section of the apparatus, and requires no description, the letters answering to the description already given.

It may be proper here just to notice the portable gas lamp of Mr. Gordon, which seems now rising into general notice in London, a company having been recently established for the purpose of supplying private families, public offices, ball rooms, theatres, &c. with compressed oil gas in lamps of various sizes, to suit the convenience of the consumer.

A representation of the general form of the portable gas lamp is given in fig. 8. Plate XVII.

The body A is made of strong copper, and may be set in a stand, as seen in the figure, or in any other ornamental support according to the taste of the person who uses it. At B there is a conical valve, similar to that in the reservoir of an air gun; this valve is regulated by means of a screw which presses it inwards, so that the size of the flame may be varied at pleasure; and the whole is surrounded by a moon-glass C, within which is a common glass chimney. Into the reservoir of the lamp any requisite number of atmospheres of gas may be forced by a powerful condensing engine, which, at the company's manufactory, is worked by steam.

To force in the gas into each vessel separately, as the air is forced into the reservoir of an air-gun, would be attended with much inconvenience and expence. To obviate this inconvenience, Mr. Gordon condenses the air in a large vessel of cast iron, from whence it is drawn off into the small reservoir belonging to the individual lamp.

GASTEROSTEUS, the *stickle-back*, in natural history, a genus of fishes of the order Thoracici. There are thirteen species. G. aculeatus, or three spined stickle-back is found in almost all the fresh waters of Europe, and is about three inches long, and in the beginning of the summer displays the most beautiful combination of bright-red, fine olive green, and silvery whiteness. It is extremely active and rapid, and is particularly injurious in fish ponds, as it devours the spawn of the fish. In the fens of Lincolnshire, these fishes appear in immense numbers, and have been frequently sold at the rate of a halfpenny per bushel. They have been often most successfully applied as manure for land.

GASTRIC *juice*, a fluid of the utmost importance in the process of digestion. It does not act indiscriminately on all substances, nor is it the same in all animals, nor does it continue always of the same nature even in the same animal, it changes according to circumstances. It acts with a chemical energy in dissolving food: it attacks the surface of bodies, unites to the particles of them, which it carries off, and cannot be separated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increased by a warm temperature. The food is not merely reduced to very minute parts; its taste and smell are quite changed; its sensible properties are destroyed, and it acquires new and very different ones. This fluid does not act as a ferment, it is a powerful antiseptic, and even restores flesh already putrified.

GASTROBRANCHUS, in natural history, a genus of fishes, of the order Cartilaginei. Generic character; mouth beneath, furnished with pectinal teeth, in a double row on each side: body eel-shaped, carinate beneath by a soft fin, two ventral spiracles. G. cœcus or the hag-fish, is about five inches in length, in the European seas, but, in those of India attains the length of a common eel. It is characterized by the circumstance of exhibiting no traces of the existence of such an organ as the eye. It will often enter the mouths of fishes fixed on the hook of the angler, and gnaw a passage through their bodies, devouring all but the bones and skin. Its substance is so highly glutinous, that a large vessel of sea water will, in a short time after the living cœcus is placed in it, become of the consistence of jelly.

GATE, in architecture, a large door, leading, or giving entrance into a city, town, castle, palace, or other considerable building: or a

place giving passage to persons, horses, coaches, or waggons, &c.

GAVELKIND, a tenure of custom belonging to lands in the county of Kent, by which the lands of the father are at his death, equally divided among all his sons; or the land of a deceased brother, in case he leaves no issue, among all the brethren. This is by some called ancient soccage-tenure: the custom came from our Saxon ancestors, among whom the inheritance of lands did not descend to the eldest, but to all the sons alike; and the reason why it was retained in Kent is, because the Kentish men were not conquered by the Normans. The customs attending this tenure are, that the heir, at the age of fifteen, may give or sell his lands in gavelkind; and though the father is attainted of treason, and suffers death, the son inherits. A wife shall be endowed of a moiety of the gavelkind lands, of which her husband died seised, during her widowhood. Likewise a husband may be tenant by courtesy of half his wife's lands, without having any issue by her; but if he marries again, not having issue, he forfeits his tenancy.

GAUGE-*point*, of a solid measure, the diameter of a circle, the area of which is equal to the solid content of the same measure. Thus the solidity of a wine-gallon being 231 cubic inches, if you conceive a circle to contain so many inches, the diameter of it will be 17.15; and that will be the gauge-point of wine-measure. And if an ale-gallon, containing 282 cubic inches, by the same rule, the gauge-point for ale-measure will be found to be 19.15. After the same manner, may the gauge-point of any foreign measure be obtained; and hence may be drawn this consequence, that when the diameter of a cylinder, in inches, is equal to the gauge-point of any measure, given likewise in inches, every inch in length thereof will contain an integer of the same measure, *e. gr.* in a cylinder whose diameter is 17.15 inches, every inch in height contains one entire gallon in wine-measure; and in another, whose diameter is 18.95 inches, every inch in length contains one ale-gallon.

GAUGING, the art or act of measuring the capacities or contents of all kinds of vessels, and determining the quantities of fluids or other matters contained therein.

As the practice of gauging depends entirely on the art of mensuration, the reader is referred to that article.

GAURA, a genus of the class and order octandria monogynia. There is one species, a biennial plant of North America.

GAURS, for some account of this ancient sect. See Gabres.

GAUZE, in commerce, a thin transparent stuff, sometimes woven with silk, and sometimes only of thread. Gauzes are either plain or figured; the latter are worked with flowers of silver or gold, on a silk ground; and are chiefly imported from China. Gauzes of excellent quality, are now manufactured at Paisley.

GAZELLA. See Antelope.

GAZETTE, a newspaper, or printed account of the transactions of all the countries in the known world, in a loose sheet, or half sheet. This name is with us confined to that paper of news published by authority.

The first gazette in England was published at Oxford, the court being there, Nov. 7, 1665. On the removal of the court to London, the gazette was published there. In this work are recorded all commissions and promotions in the army; all state appointments of consequence, with a variety of matters interesting to men of business and others.

GAZONS, in fortification, pieces of fresh earth, covered with grass, and cut in form of a wedge, about a foot long, and half a foot thick, to line the outsides of works made of earth, as ramparts, parapets, &c.

GELATIN, Gelly, or *jelly*, an animal substance, soluble in water, capable of assuming a well-known elastic or tremulous consistence, by cooling, when the water is not too abundant, and liquefiable again by increasing its temperature. This last property distinguishes it from albumen, which becomes consistent by heat. It is precipitated in an insoluble form by tannin; and it is this action of tannin on gelatin that is the foundation of the art of tanning leather. See Glue.

According to the analysis of MM. Gay Lussac and Thenard, gelatin is composed of

Carbon -	47.881
Oxygen -	27.207
Hydrogen	7.914
Azote	16.998
	100.000

GEMS. This word is used to denote such stones as are considered by mankind as precious. These are, the diamond, the ruby, the sapphire, the topaz, the chrysolite, the beryl, the emerald, the hyacinth, the amethyst, the garnet, the tourmalin, the opal; and to these may be added, rock crystal, the finer flints of pebbles, the cat's eye, the oculus mundi, or hydrophanes, the chalcedony, the moon-stone, the onyx, the cornelian, the sardonyx, agates, and the Labrador-stone.

Gems, *imitation of antique*. There has been at different times a method practised by particular persons, of taking the impressions and figures of antique gems, with their engravings, in glass of the colour of the original gem. This has always been esteemed a very valuable method, and preferable to the more ordinary ones of doing it on sealing-wax or brimstone; but, this art, being a secret only in the hands of some particular persons, it died with them, and every new artist was obliged to re-invent the method; till at length Mr. Homberg, having found it in great perfection, gave the whole process to the world to be no more forgotten or lost; and since that time it has been very commonly practised in France, and other places.

Mr. Homberg was favoured in his attempts with all the engraved gems of the king's cabinet, and took such elegant impressions, and made such exact resemblances of the originals, that the nicest judges were deceived in them, and often mistook them for the true antique stones.

The great care in the operation is, to take the impression of the gem in a very fine earth, and to press down upon this a piece of proper glass, softened or half melted, so that the figures of the impression made in the earth may be nicely and perfectly expressed upon the glass. Of all the species of earth which

Mr. Homberg examined on this occasion. none proved so much divested of salts, or so fit for the purpose, as the common tripoli, used to polish glass and stones.

When the tripoli has been properly prepared it is mixed with water to the consistence of paste; it is then put into a crucible of a flat form, and of about half an inch in depth, and pressed lightly down, after which the surface must be strewed with some dry tripoli of the yellow kind, and the gem of which the impression is to be taken is then to be pressed evenly down into the paste with a finger and thumb, and then carefully removed. When the crucible and paste are dry, a piece of glass must be chosen of a proper colour, and cut to a size proper for the figure; this must be laid over the mould, but in such a manner that it shall not touch the figures, otherwise it would spoil them. The crucible is then to be brought near the furnace by degrees, and gradually heated; then it is to be placed in the furnace under a muffle surrounded with charcoal. Several of these small crucibles may be placed under one muffle; and when they are properly disposed, the aperture of the muffle should have a large piece of burning charcoal put to it, and then the operator must watch the process, and see when the glass begins to look bright; this is the signal of its being fit to receive the impression. The crucible is then to be taken out of the fire, and the hot glass must be pressed down upon the mould with an iron instrument, to make it receive the regular impression; as soon as this is done, the crucible is to be set by the side of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glass is to be taken out, and its edges should be grated round with pincers, in order to prevent its flying afterwards, which is an accident that sometimes happens when this caution has been omitted, especially when the glass is naturally tender. This process however is tedious and precarious, and a much simpler method is now made use of, viz. substituting plaster of Paris moulds in place of the tripoli; the other parts of the process being nearly the same as already described.

Of all the artists and ingenious men who have taken impressions of engraved gems in sulphur and in paste, no one seems to have carried that art to such perfection as Mr. James Tassie, a native of Glasgow, and whose method is still practised by his successor Mr. William Tassie of Liecester Square, London.

Mr. Tassie, profiting by the former publications of this sort, and by expence, industry, and access to many cabinets in England and other kingdoms to which former artists had not obtained admission, greatly increased his collection of impressions of ancient and modern gems. It is the greatest collection of this kind that ever existed, and serves for all the purposes of artists, antiquaries, scholars, men of taste, and philosophers. The great demand for his pastes was perhaps owing in the beginning to the London jewellers, who introduced them into fashion by setting them in rings, seals, bracelets, necklaces, and other trinkets.

The reputation of this collection having reached the empress of Russia, she was pleased to order a complete set; which, being accordingly executed in the best and most durable manner, were arranged in elegant cabinets, and are now placed in the noble apartments of her imperial majesty's superb palace at Czarsko Zelo.

Mr. Tassie, in executing this commission, availed himself of all the advantages which the improved state of chemistry, the various ornamental arts, and the knowledge of the age, seemed to afford. The impressions were taken in a beautiful white enamel composition, which is not subject to shrink or form air-bladders, which emits fire when struck with steel, and takes a fine polish, and which shows every stroke and touch of the artist in higher perfection than any other substance. When the colours, mixed colours, and nature of the respective originals, could be ascertained, they were imitated as completely as art can imitate them; insomuch that many of the paste intaglios and cameoes in this collection are such faithful imitations, that artists themselves have owned they could hardly be distinguished from the originals.

Mr. Tassie's collection now amounts to upwards of 20,000 articles.

GENDARMES, or *Gens d'armes*, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

GENEALOGICA *arbor*, or tree of consanguinity, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside each other.

GENEALOGY, an enumeration of a series of ancestors: or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

GENERAL, in a military sense, is an officer in chief, to whom the prince or senate of a country have judged proper to intrust the command of their troops. He holds this important trust under various titles: as captain-general, in England and Spain; feldt mareschal in Germany, or mareschal in France.

In the British service the king is constitutionally, and in his own proper right, captain-general. He has ten aid-de-camps: every one of whom enjoys the brevet rank of full colonel in the army. Next to his majesty is the commander-in-chief, whom he sometimes honours with the title of captain-general.

GENERALISSIMO, a supreme and absolute commander in the field. This word is generally used in most foreign languages. It was first invented by the absolute authority of cardinal Richelieu, when he went to command the French army in Italy.

GENERAL *issue*, in law, is that plea which traverses and denies at once, the whole declaration or indictment, without offering any special matter, whereby to evade it: and it is called the general issue, because, by importing an absolute and general denial of what is alleged in the declaration, it amounts at once to an issue; that is, a fact affirmed on one side, and denied on the other. This is the ordinary

plea upon which most causes are tried, and is now almost invariably used in all criminal cases. It puts every thing in issue, that is, denies every thing, and requires the party to prove all that he has stated.

GENERATING *line*, or *figure*, in geometry, is that by which its motion produces any other plane or solid figure. Thus a right line moved any way parallel to itself, generates a parallelogram; round a point in the same plane, with one end fastened in that point, it generates a circle. One entire revolution of a circle, in the same plane, generates the cycloid; and the revolution of a semi-circle round its diameter, generates a sphere, &c.

GENERATION. See PHYSIOLOGY.

GENERICAL *name*, in natural history, the word used to signify all species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the generical name, equally expresses every one of them, and some other words expressive of the peculiar qualities of figures of each are added, in order to denote them singly, and make up what is called the specific name. Thus the word rosa, or rose, is the generical name of the whole series of flowers of that kind, which are distinguished by the specific names of the red-rose, the white-rose, the apple-rose, &c.

GENEVA, *gin*, a hot fiery spirit, too much used by the lower classes of people in this country, as a dram, and is unquestionably most injurious to their constitution and morals. A liquid of this kind was formerly sold in apothecaries' shops, drawn from the juniper-berry, but distillers now have completely supplanted the trade of the apothecary, who sell it under the name of geneva, or gin, in which juniper-berries make no part of the composition. It is composed of oil of turpentine, and malt spirits. The Hollands geneva is manufactured chiefly at a village near Rotterdam, from wheat and juniper-berries.

GENIOSTOMA, a genus of the monogynia order, in the pentandria class of plants. There is one species, a native of the South Seas.

GENISTA, BROOM, or DYER'S WEED, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order papilionaceæ. There are 17 species, of which the most remarkable are the cytiso-genista, or common broom, and the tinctoria, or dyer's-weed.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently, and with a great deal of pains.

GENTIANA, *gentian*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. There are 53 species. The most remarkable are the following:

1. The *lutea*, or common gentian of the shops. This is a native of the mountainous parts of Germany, whence the roots, the only part used in medicine, are brought to this country. They have a yellowish-brown colour, and a very bitter taste.

2. The *centaureum*, or lesser centaury of the shops, is a native of many parts of Britain. It grows on dry pastures, and its height is commonly proportioned to the goodness of the soil. It is an annual plant, with upright branching stalks, and small leaves, placed by pairs.

3. The *acaulis*, a beautiful little plant for the flower garden, conspicuous for its fine changeable azure blue flowers. It is a native of the Alps

GENUS, among metaphysicians and logicians, denotes a number of beings, which agree in certain general properties, common to them all.

GENUS, in natural history, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters.

GEOCENTRIC, in astronomy, is applied to a planet or its orbit to denote it concentric with the earth.

GEOCENTRIC *latitude of a planet*, is its distance from the ecliptic, as it is seen from the earth.

GEOCENTRIC *place of a planet*, the place in which it appears to us from the earth, supposing the eye there fixed: or it is a point in the ecliptic in which a planet seen from the earth is referred.

GEOGRAPHY, is a term derived from two Greek words γη or γεα *the earth*, and γραφω *I write*, and properly signifies *a description of the earth*.

What is called general geography embraces a wide view of the subject; regarding the earth astronomically as a planet, the grand divisions of land and water, the winds, tides, meteorology, and may extend to what is called mechanical geography, including directions for the construction of globes, maps, and charts. The study of geography being of so much practical importance in life, must have commenced in the early ages of the world. It was regarded as a science by the Babylonians and Egyptians, from whom it passed to the Greeks, and from these to the Romans, the Arabians, and the western nations of Europe. Thales of Miletus, in the 6th century before Christ, first made observations on the apparent progress of the sun from tropic to tropic; and is said to have written two treatises, the one on the tropic, and the other on the equinox, whence he was led to the discovery of the four seasons, which are determined by the equinoxes and solstices. We are assured this knowledge was obtained by means of the gnomon. Thales, it is also said, constructed a globe, and represented the land and sea upon a table of brass.

Maps at first were little more than rude outlines, and topographical sketches of different countries. The earliest on record were those of Sesostris, mentioned by Eustathius, who says that "this Egyptian king, having traversed great part of the earth, recorded his march in maps, and gave copies of them not only to the Egyptians, but to the Scythians, to their great astonishment." Some have imagined, with much probability, that the Jews made a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh; for Joshua tells us that they were sent

to walk through the land, and that they described it in seven parts of a book; and Josephus relates that when Joshua sent out people from the different tribes to measure the land, he gave them as companions persons well skilled in geometry, who could not be mistaken in the truth.

The first Grecian map on record was that of Anaximander, mentioned by Strabo, supposed to be that referred to by Hipparchus under the designation of the ancient map.

Eratosthenes first attempted to reduce geography to a regular system, and introduced a regular parallel of latitude, which began at the straits of Gibraltar, passed eastward through the isle of Rhodes, and so on to the mountains of India, noting all the intermediate places through which it passed. In drawing this line, he was not regulated by the same latitude, but by observing where the longest day was 14 hours and a half, which Hipparchus afterwards determined was the latitude of 36 degrees.

This first parallel through Rhodes was ever after considered with a degree of preference, in constructing all the ancient maps; and the longitude of the then known world was often attempted to be measured in stadia and miles, according to the extent of that line, by many succeeding geographers.

Though the maps of Eratosthenes were the best of his time, they were yet very imperfect and inaccurate. They contained little more than the states of Greece, and the dominions of the successors of Alexander, digested according to the surveys above-mentioned. He had indeed seen, and has quoted, the voyages of Pythias into the great Atlantic ocean, which gave him some faint ideas of the western parts of Europe; but so imperfect, that they could not be realized into the outlines of a chart Strabo says he was very ignorant of Gaul, Spain, Germany, and Britain; and he was equally ignorant of Italy, the coast of the Adriatic, Pontus, and all the countries towards the north.

Such was the state of geography, and the nature of the maps, before the time of Hipparchus. He made a closer connection between geography and astronomy, by determining the latitudes and longitudes from celestial observations.

The Roman empire had been enlarged to its greatest extent, and all its provinces well known and surveyed, when Ptolemy, about 150 years after Christ, composed his system of geography. The chief materials he employed in composing this work, were the proportions of the gnomon to its shadow, taken by different astronomers at the times of the equinoxes and solstices; calculations founded on the length of the longest days; the measured or computed distances of the principal roads contained in their surveys and itineraries; and the various reports of travellers and navigators. All these were compared together, and digested into one uniform body or system; and afterwards were translated by him into a new mathematical language, expressing the different degrees of latitude and longitude, after the invention of Hipparchus, which had been neglected for 250 years.

Ptolemy's system of geography, notwithstanding it was still very imperfect, continued in vogue till the last three or four centuries, within which time the great improvements in astronomy, the many discoveries of new countries by voyagers, and the progress of war and arms, have contributed to bring it to a very considerable degree of perfection.

General Principles of Geography.

The general principles of geography are, the spherical figure of the earth, its rotation on its axis, its revolution round the sun, and the position of the axis or line round which it revolves with regard to the celestial luminaries. That the earth and sea taken together constitute one vast sphere is demonstrable by the following arguments: 1. To people at sea the land disappears, though near enough to be visible, was it not for the intervening convexity of the water. 2. The higher the eye is, the more extensive is the prospect; whence it is common for sailors to climb up to the tops of the masts to discover land or ships at a distance. 3. To people on shore, the mast of a ship at sea appears before the hull; but were the earth an even plane, not the highest objects, but the largest, would be longest visible. 4. The convexity of any piece of still water of a mile or two in extent may be perceived by the eye A little boat, for instance, may be perceived by a man who is any height above the water; but if he stoops down or lays his eye near the surface, he will find that the fluid appears to rise and intercept the view of the boat entirely. 5. The earth has been often sailed round, as by Magellan, Drake, Dampier, Anson, Cook, and many other navigators, which demonstrates that the surface of the ocean is spherical.

A great many of the terrestrial phenomena depend upon the globular figure of the earth, and the position of its axis with regard to the sun, particularly the rising and setting of the celestial luminaries, the length of the days and nights, &c.

Though the sun rises and sets all over the world, the circumstances of his doing so are very different in different countries. The most remarkable of these circumstances is the duration of the light, not only of the sun himself, but of the twilight before he rises and after he sets. In the equatorial regions, darkness comes on very soon after sunset. In our climate the twilight always continues about two hours, and during the summer season it continues in a considerable degree during the whole night. In countries farther to the northward or southward, the twilight becomes brighter and brighter as we approach the poles, until at last the sun does not appear to touch the horizon, but goes in a circle at some distance above it for many days successively. In like manner, during the winter, the same luminary sinks lower and lower, until at last he does not appear at all; and there is only a dim twinkling of twilight for an hour or two in the middle of the day. By reason of the refraction of the atmosphere, however, the time of darkness, even in the most inhospitable climates, is always less than that of light. In the warmer climates the sun has often a beautiful appearance at rising and setting, from the refraction of his light through the vapours which are copiously raised in those parts. In the colder regions, halos, parhelia, aurora

borealis, and other meteors, are frequent; the two former owing to the great quantity of vapour continually flying from the warm regions of the equator to the colder ones of the poles. In the high northern latitudes, thunder and lightning are unknown, or but seldom heard of; but the more terrible phenomena of earthquakes, volcanoes, &c. are by no means unfrequent. These, however, seem only to affect islands and the maritime parts of the continent.

Were the earth a perfect plane, the sun would appear to be vertical in every part of it; for, in comparison with the immense magnitude of that luminary, the diameter of this globe itself is but very small; and as the sun, were he near to us, would do much more than cover the whole earth, so, though he were removed to any distance, the whole diameter of the latter would make no difference in the apparent angle of altitude. By means of the globular figure of the earth also, along with the great disparity between the diameters of the two bodies, some advantage is given to the day over the night; for thus the sun, being immensely the larger of the two, shines upon more than one half of the earth; whence the unenlightened part has a shorter way to go before it again receives the benefit of his rays. This difference is greater in the inferior planets Venus and Mercury than in the earth.

To the globular figure of the earth likewise is owing the long moonlight which the inhabitants of the polar regions enjoy. The same thing likewise occasions the appearance and disappearance of certain stars at some seasons of the year in some countries; for, were the earth flat, they would all be visible in every part of the world at the same time.

In geography the circles which the sun apparently describes in the heavens are supposed to be extended as far as the earth, and marked on its surface; and in like manner we may imagine as many circles as we please to be described on the earth, and their planes to be extended to the celestial sphere, till they mark concentric ones on the heavens. The most remarkable of those supposed by geographers to be described in this manner are the following:

1. The horizon. This is probably a double circle, one of the horizons being called the sensible, and the other the rational. The former comprehends only that space which we can see around us upon any part of the earth, and which is very different according to the difference of our situation. The other, called the rational, is a circle parallel to the former, and passing through the centre of the earth, supposed to be continued as far as the celestial sphere itself. To the eyes of the spectators there is always a vast difference between the sensible and rational horizons; but from the immense disparity betwixt the size of the earth and celestial sphere, planes of both circles may be considered as coincident. Hence in geography, when the horizon, or plane of the horizon, is spoken of, the rational is always understood when nothing is said to the contrary. In consequence of the round figure of the earth, every part has a different horizon. The poles of the horizon, that is, the points directly above the head, and opposite to the feet of the observer, are called the zenith and nadir.

2. A great circle described upon the sphere of the heaven, and passing through the two vertical points, is called a vertical circle, or an azimuth; and of these we may suppose as many as we please all round the horizon. In geography every circle obtains the epithet of great, whose plane passes through the centre of the earth; in other cases they are called lesser circles.

3. Almucantars are circles supposed to be drawn upon the sphere parallel to the horizon, and grow less and less as they approach the vertical points, where they entirely vanish.

The apparent distances between any two celestial bodies are measured by supposing arches of great circles drawn through them, and then finding how many degrees, minutes, &c. of these circles are intercepted between them.

4. Sometimes the visible horizon is considered only with regard to the objects which are upon the earth itself, in which case we may define it to be a lesser circle on the surface of the earth, comprehending all such objects as are at once visible to us; and the higher the eye, the more is the visible horizon extended. It is most accurately observed, however, on the sea, on account of the absence of those inequalities which at land render the circle irregular.

5. The equator is a great circle upon the earth, every part of which is equally distant from the poles or extremities of the imaginary line on which the earth revolves. In sea-language, it is usually called the line.

6. The meridian of any place is a great circle on the earth drawn through that place and both poles of the earth. It cuts the horizon at right angles, marking upon it the true north and south points; dividing also the globe into two hemispheres, called the eastern and western, from their relative situation to that place and to one another. The poles divide the meridians into two semicircles, one of which is drawn through the place to which the meridian belongs, the other through that point of the earth which is opposite to the place. By the meridian of a place, geographers and astronomers often mean that semicircle which passes through the place, and which may therefore be called the geographical meridian. All places lying under this semicircle are said to have the same meridian; the semicircle opposite to this is called the opposite meridian. The meridians are thus immoveably fixed to the earth as much as the places themselves on its surface, and are carried along with it in its diurnal rotation. When the geographical meridian of any place is, by the rotation of the earth, brought to point at the sun, it is noon or mid-day at that place. The rotation of the earth is from west to east; whence the celestial bodies appear to move the contrary way. East and west, however, are terms merely relative, since a place may be west from one part of the earth, and east from another; but the true east and west points from any place are those where its horizon cuts the equator.

7. All places lying under the same meridian are said to have the same longitude, and those which lie under different meridians to have different longitudes; the difference of longitude being reckoned eastward or westward on the equator. Thus, if the meridian of any place cuts the equator in a point 15 degrees dis

tant from one another, we say there is a difference of 15° longitude betwixt these two places. Geographers usually fix upon the meridian of some remarkable place for the first meridian, and reckon the longitude of all others by the distance of their meridians from that which they have determined upon as the first; measuring sometimes eastward on the equator all around the globe, or sometimes only one half east and the other west; according to which last measurement no place can have more than 180° longitude either east or west. By the British geographers the royal observatory at Greenwich is accounted the place of the first meridian.

8. If we suppose 12 great circles, one of which is the meridian to a given place, to intersect each other at the poles of the earth, and divide the equator into 24 equal parts, these are the hour-circles of that place. These are by the poles divided into 24 semicircles, corresponding to the 24 hours of the day and night. The distance betwixt each two of these semicircles is 15°, being the 24th part of 360; and by the rotation of the earth each succeeding semicircle points at the sun one hour after the preceding: so that in 24 hours all the semicircles point successively at the sun. Hence it appears, that such as have their meridian 15° east from any other have likewise noon one hour sooner, and the contrary; and in like manner every other hour of the natural day is an hour sooner at the one place than at the other. Hence, from any instantaneous appearance in the heavens observed at two distant places, the difference of longitude may be found, if the hour of the day is known at each place. Hence also, were a man to travel or sail round the earth from west to east, he would reckon one day more to have passed than they do who stay at the place whence he set out; so that their Monday would be his Tuesday, &c.

9. The equator divides the earth into two hemispheres, called the northern and southern; all places lying under the equator are said to have no latitude; and all others to have north or south latitude according to their situation with respect to the equator. The latitude itself is the distance from the equator measured upon the meridian, in degrees, minutes, and seconds. The complement of latitude is the difference between the latitude itself and 90°, or as much as the place itself is distant from the pole; and this complement is always equal to the elevation of the equator above the horizon of the place. An inhabitant of the earth at either of the poles would have always one of the celestial poles in his zenith, and the other in his nadir, the equator coinciding with the horizon.

Those who live under the equator have both poles in the horizon, all the celestial parallels cutting the horizon, at right angles. Lastly, those who live between either of the poles and the equator, are said to live in an oblique sphere, or to have an oblique horizon, because the celestial equator cuts their horizon obliquely, and all the parallels in the celestial sphere have their planes oblique to that of the horizon.

By the arctic and antarctic circles, however, modern geographers understand two fixed circles at the distance of 23½ degrees from the pole. These are supposed to be described by the poles of the ecliptic, and mark out the space all around the globe where the sun appears to touch the horizon at midnight in the summer time, and to be entirely sunk below it in the winter. These are also called the polar circles.

According to the different positions of the globe with regard to the sun, the celestial bodies will exhibit different phenomena to the inhabitants. Thus, in a parallel sphere, they will appear to move in circles round the horizon; in a right sphere they would appear to rise and set as at present, but always in circles, cutting the horizon at right angles; but in an oblique sphere the angle varies according to the degree of obliquity, and the position of the axis of the sphere with regard to the sun. Hence we easily perceive the reason of the sun's continual change of place in the heavens; but though it is certain that this change takes place every moment, the vast distance of the luminary renders it imperceptible for some time, unless to very nice astronomical observers. Twice a-year he is in the equator, and then the days and nights are nearly equal all over the earth. This happens in the months of March and September; after which the sun proceeding either northward or south, according to the season of the year and the position of the observer, the days become longer or shorter than the nights, and summer or winter comes on. The secession of the sun from the equator either northward or southward is called his declination, and is either north or south according to the season of the year; and when this declination is at its greatest height, he is then said to be in the tropic, because he begins to turn back (the word tropic being derived from the Greek *τρεπω, verto*). The space between the two tropics, called the torrid zone, extends 47 degrees of latitude all round the globe; and throughout the whole of that space the sun is vertical to some of the inhabitants twice a year, but to those who live directly under the tropics only once. Throughout the whole torrid zone also there is little difference between the length of the days and nights.

From an observation of the diversity in the length of the days and nights, the rising and setting of the sun, with the other phenomena already mentioned, geographers divide the surface of the earth into certain districts, which they call climates. This method of dividing the surface of the earth into climates is not of real practical utility, since it does not furnish any certain criterion for judging of the climate in a meteorological point of view.

From the various appearances of the sun, and the effects of his light and heat upon different parts of the earth, the division of it into zones has arisen. These are five in number. 1. The torrid zone, lying between the two tropics for the space of 47° of latitude. This is divided into two equal parts by the equator. 2. The two temperate zones lie between the polar circles and the tropics, containing a space of 43° of latitude. And, 3. The two frigid zones lie between the polar circles and the poles. In these last the longest day is never below 24 hours; in the temperate zones it is never quite so much, and in the torrid zone it is never above 14. The zones are named from the degree of heat they were supposed to be subjected to. The torrid zone was supposed

by the ancients to be uninhabitable, on account of its heat; but this is now found to be a mistake, and many parts of the temperate zones are warmer than the torrid zone itself. Towards the polar circles also these zones are extremely cold during the winter season. Only a small part of the northern frigid zone, and none of the southern, is inhabited. Some geographers reckoned six zones, dividing the torrid zone into two by the equator.

Besides these there are other terms belonging to geography which it is necessary to explain.

A *continent* is a large portion of the earth, which comprehends several countries that are not separated by any sea; such are Europe, Asia, Africa, and America. An *island* is part of the earth entirely surrounded by water; as Great Britain. A *peninsula* is a tract of land almost surrounded with water, and is joined to a continent only by a narrow neck; such is the Morea in Greece. An *isthmus*, or neck of land, is that part by which a peninsula is joined to a continent, or two continents together; as the isthmus of Suez, which joins Africa to Asia. A *promontory*, or cape, is a high part of land which stretches into the sea; thus the Cape of Good Hope is a promontory. An *ocean* is a vast collection of waters surrounding a considerable part of the continent; as the Atlantic. A *sea* is a smaller collection of waters; as the Black Sea. A *gulf* is a part of the sea which is nearly surrounded with land; as the gulf of Venice. A *bay* has a wider entrance than a gulf; as the Bay of Biscay. A *strait* is a narrow passage that joins two seas; as the Strait of Gibraltar, which joins the Mediterranean to the Atlantic. A *lake* is a large collection of water entirely surrounded by land, having no visible communication with the sea; as the Caspian in Asia. A *river* is a stream of water that has its source from a spring, which keeps constantly running till it falls into some other river, or into the sea.

The ancients considered the globe under the three grand divisions of Asia, Europe, and Africa. Modern discoveries have added a fourth division, that of America, which, exceeding even Asia in size, might have been admitted under two grand and distinct denominations, limited by the isthmus of Darien. The vast extent of New Holland which seems too large to be ranked among islands, and too small for a continent, eludes the petty distinctions of man; and geographers hesitate whether to ascribe it to Asia, or to denominate it a fifth specific division of the earth.

Of the grand divisions of the earth, Asia has ever been esteemed the most populous; and is supposed to contain five hundred millions of souls. The population of Africa may be estimated at thirty millions, of America at twenty millions, and two hundred millions may perhaps be assigned to Europe.

The natural division of the surface of the globe is into sea and land; about three-fourths of the whole being occupied by water. The remaining fourth consists of lands, elevated more or less above the level of the sea, interspersed, in some parts, with smaller collections of water, at various heights, and in a few instances, somewhat lower than the general surface of the main ocean. Thus the Caspian Sea is said to be about three hundred feet lower than the ocean.

The great continent, composed of Europe, Asia, and Africa, constitutes about a seventh of the whole surface of the earth; America about a sixteenth; and Australasia, or New South Wales, about a fiftieth; or in hundredth parts of the whole, Europe contains two; Asia, seven; Africa, six; America, six; and Australasia, two; the remaining seventy-seven being sea; although some authors assign seventy-two parts only out of one hundred to the sea, and twenty-eight to the land.

The general inclinations and levels of the continents are discovered by the course of their rivers. Of these the principal are, the river of Amazons, the Senegal, the Nile, the river St. Lawrence, the Hoangho, the river La Plata, the Yenisei, the Mississippi the Volga, the Oby, the Amur, the Oronooko, the Ganges, the Euphrates, the Danube, the Don, the Indus, the Dnieper, and the Dwina; and this is nearly the order of their magnitudes. But if we class them according to the length of country through which they run, the order will, according to Major Rennel's calculation, be somewhat different; taking the length of the Thames for unity, he estimates that of the river of Amazons, at 15¾; the Kian Kew, in China, 15½; the Hoangho, 13½; the Nile, 12½; the Lena, 11½; the Amur, 11; the Oby, 10½; the Yenisei, 10; the Ganges, its companion the Burrampooter, the river of Ava, and the Volga, each 9½; the Euphrates, 8½; the Mississippi, 8; the Danube, 7; the Indus, 5½; and the Rhine, 5¼.

The grandest concavity of this globe is filled by the Pacific Ocean; occupying nearly half its surface from the eastern shores of New Holland, to the western coast of America, and diversified with several groups of islands, which seem in a manner the summits of vast mountains emerging from the waves This ocean receives but few rivers, the chief being the Amur from Tartary, the Hoan Ho and Kian Kew from China, while the principal rivers of America run towards the east.

Next to this in magnitude is the Atlantic, between the Old and New Continents; and the third is the Indian Ocean. The seas between the arctic and antarctic circles and the poles, have been sometimes styled the Arctic and Antarctic Oceans; but the latter is only a continuation of the Pacific, Atlantic, and Indian Oceans; while the Arctic Sea is partly embraced by continents, and receives many important rivers. Besides these, there are other seas more minute, as the Mediterranean, the Baltic, and others still smaller, till we come by due gradation to inland lakes of fresh water.

The courses of rivers are sometimes marked by oblong concavities, which generally at first intersect the highest grounds, till the declivity becomes more gentle on their approach towards their inferior receptacles. But even large rivers are found sometimes to spring from lowland marshes, and wind through vast plains, unaccompanied by any concavity, except that of their immediate course; while on the other hand, extensive vales, and low hollow spaces, frequently occur destitute of any stream. Rivers will also sometimes force a passage where nature has erected mountains and rocks against it, and where the concavity would appear to be

in another direction, which the river might have gained with more ease. In like manner, though the chief mountains of Europe extend in a south-easterly and north-westerly direction, yet there are so many exceptions, and such numerous and important variations in other parts of the globe, as to render any attempt at a general theory vain.

Prom the vast expanse of oceanic waters, arises in the ancient hemisphere, that wide continent, which contains Asia, Europe, and Africa: and in the modern hemisphere the continent of America, which forms a kind of separate island, divided by a strait of the sea from the ancient continent. But the grandest division of the ancient continent is Asia, the parent of nations, and of civilization: on the north-east and south, surrounded by the ocean; but on the west, divided by an ideal line from Africa; and from Europe by boundaries not very strongly impressed by the hand of nature. The Russian and the Turkish empires, extending over large portions of both continents, intimately connect Asia with Europe. But for the sake of clearness and precision, geographers retain the strict division of the ancient continent into three parts, which if not strictly natural, is ethical, as the manners of the Asiatic subjects of Russia, and even of Turkey, differ considerably from those of the European inhabitants of those empires.

A description of the four quarters of the globe, and of the several kingdoms and states into which they are divided, belongs rather to a work devoted exclusively to geography, than to a dictionary of arts and sciences: we shall therefore forbear entering more into detail in this article.

GEOLOGY. The term geology is used to signify a description of the structure of the earth. As a branch of inductive science, geology is of very modern date; for though the attention of men has long been directed to a theory of the earth, the formation of such a theory is incompatible with any but an advanced state of physical knowledge. Few studies, indeed, are attended with greater difficulty; none in which the subject is more complex; appearances so diversified and scattered; and where the causes that have operated are so remote from the sphere of ordinary observation. Works on the subject of geology are multiplying at the present time with unexampled rapidity; to suppose, however, that they are all either interesting or useful would be absurd; and the inquirers on this interesting subject will find the most satisfactory and scientific information from the writings of such men as Greenough, Conybeare, Philiips, Buckland, D' Aubuisson; and the justly celebrated Cuvier.

The following brief sketch of the subject is taken from the excellent view given of this science in a work by Messrs. Conybeare and Phillips, entitled Outlines of the Geology of England and Wales. Some additions by Dr. Ure occasionally occur, and are marked with asterisks. This study may be divided, like most others, into two parts; observation and theory. By the first we learn the relative positions of the great rocks or mineral aggregates that compose the crust of our globe; through the second, we endeavour to penetrate into the causes of these collocations.

WERNER'S *Table of the different Mountain Rocks, from Jameson.*

CLASS I.—*Primitive rocks.*

1. Granite. 2. Gneiss. 3. Mica-slate. 4. Clay-slate. 5. Primitive limestone. 6. Primitive trap. 7. Serpentine. 8. Porphyry. 9 Syenite. 10. Topaz-rock. 11. Quartz-rock. 12. Primitive flinty-slate. 13. Primitive gypsum. * 14. White stone.

CLASS II.—*Transition rocks.*

1. Transition limestone. 2. Transition trap. 3. Greywacke. 4. Transition flinty-slate. 5. Transition gypsum

CLASS III.—*Floetz rocks.*

1. Old red sandstone, or first sandstone formation. 2. First or oldest floetz limestone. 3. First or oldest floetz gypsum. 4. Second or variegated sandstone formation. 5. Second floetz gypsum. 6. Second floetz limestone. 7. Third floetz limestone. 8. Rock salt formation. 9. Chalk formation. 10. Floetz trap formation. 11. Independent coal formation. 12. Newest floetz-trap formation.

CLASS IV.—*Alluvial rocks.*

1. Peat. 2. Sand and gravel. 3. Loam 4. Bog-iron ore. 5. Nagelfluh. 6. Calc-tuff. 7. Calc-sinter.

CLASS V.—*Volcanic rocks.*

* Pseudo-volcanic rocks.

1. Burnt clay. 2. Porcelain jasper. 3. Earth slag. 4. Columnar clay ironstone. 5. Polier, or polishing slate.

** *True volcanic rocks.*

1. Ejected stones and ashes. 2. Different kinds of lava. 3. The matter of muddy eruptions.

The primitive rocks lie undermost, and never contain any traces of organized beings imbedded in them. The transition rocks contain comparatively few organic remains, and approach more nearly to the chemical structure of the primitive, than the mechanical of the secondary rocks. As these transition rocks were taken by Werner from among those which in his general arrangement were called secondary, the formation of that class made it necessary to abandon the latter term. To denote the mineral masses reposing in his transition series, he accordingly employed the term floetz rocks, from the idea that they were generally stratified in planes nearly horizontal, while those of the older strata were inclined to the horizon at considerable angles. But this holds good with regard to the structure of those countries only which are comparatively low in the Jura chain, and on the borders of the Alps and Pyrenees, Werner's floetz formations are highly inclined. Should we therefore persist in the use of this term, says Mr. Conybeare, we must prepare ourselves to speak of vertical beds of floetz, (*i. e.* horizontal,) limestone, &c. As the inquiries of geologists extended the knowledge of the various formations, Werner, or his disciples, found it necessary to subdivide the bulky class of floetz rocks into floetz and newest floetz, thus completing a fourfold enumeration. Some writers have bestowed the term *tertiary* on the newest floetz rocks of Werner. The following synoptical view of geological arrangement is given by the Rev Mr. Conybeare.

CHARACTER.	PROPOSED NAMES.	WERNERIAN NAMES.	OTHER WRITERS.
1. Formations (chiefly of *sand* and *clay*) above the chalk.	*Superior order.*	Newest floetz class.	Tertiary class.
2. Comprising, a. Chalk. b. Sands and clays, *beneath the chalk.* c. Calcareous freestones (*oolites*) and argillaceous beds. d. *New red sandstone, conglomerate, and magnesian limestone.*	*Supermedial order.*	Floetz class.	Secondary class.
3. Carboniferous rocks, comprising, a. *Coal measures.* b. *Carboniferous limestone.* c. *Old red sandstone.*	*Medial order.*	Sometimes referred to the preceding, sometimes to the succeeding class, by writers of these schools; very often the coal measures are referred to the former, the subjacent limestone and sandstone to the latter.	
4. *Roofing slates,* &c. &c.	*Submed. order.*	Transition class.	Intermed. class.
5. *Mica slate, gneiss, granite,* &c.	*Inferior order.*	Primitive class.	Primitive class.

In all these formations, from the lowest to the highest, we find a repetition of rocks and beds of similar chemical composition; i. e. siliceous, argillaceous, and calcareous, but with a considerable difference in texture; those in the lowest formations being compact and often crystalline, while those in the highest and most recent are loose and earthy. These repetitions form what the Wernerians call formation suites. We may mention,

1. The *limestone suite.* This exhibits, in the inferior or primitive order, crystalline marbles; in the two next, or transition and carboniferous orders, compact and subcrystalline limestones (Derbyshire limestone;) in the supermedial or floetz order, less compact limestone (lias,) calcareous freestone (Portland and Bath stone,) and chalk; in the superior or newest floetz order, loose earthy limestones.

2. The *argillaceous suite* presents the following gradations; clay-slate, shale of the coal measures, shale of the lias, clays alternating in the oolite series, and that of the sand beneath the chalk; and, lastly, clays above the chalk.

3. The *siliceous suite* may (since many of the sandstones of which it consists present evident traces of felspar and abundance of mica, as well as grains of quartz, and since mica is more or less present in every bed of sand,) perhaps deserve to have granite placed at its head, as its several members may possibly have been derived from the detritus of that rock: it may be continued thus; quartz rock and transition sandstone, old red sandstone, millstone-grit, and coal-grits, new red sandstone, sand, and sandstone beneath the chalk, and above the chalk. In all these instances a regular diminution in the degree of consolidation may be perceived in ascending the series

We noticed before, that the remains of vegetables and animals are confined to the secondary formations. We have now to add, that they are not irregularly dispersed throughout the whole series of these formations, but disposed as it were in families, each formation containing an association of species peculiar in many instances to itself, widely differing from those of other formations, and accompanying it throughout its whole course; so that at two distinct points on the line of the same formation, we are sure of meeting the same general assemblage of fossil remains. It will serve to exemplify the laws which have been stated, if the observer's attention is directed to two of the most prominent formations of this island; namely, the chalk and the limestone which underlie the coal in Northumberland, Derbyshire, South Wales, and Somerset. Now if he examines a collection of fossils from the chalk of Flamborough-Head, or from that of Dover-Cliffs, or, it may be added, from Poland or Paris, he will find eight or nine species out of ten the same; he will observe the same echinites associated with the same shells; nearly one-half of these echinites he will perceive to belong to divisions of that family unknown in a recent state, and indeed in any other fossil bed except the chalk. If he next proceeds to inspect parcels of fossils from the carboniferous limestone, he will in the same manner find them to agree with each other, from whichever of the above localities they may have been brought; that is, he will find the same corals, the same ehcinites, the same productæ, terebratulæ, spiriferæ, &c. But, lastly, if he compares the collection from the chalk with that from the mountain lime, he will not find one single instance of specific agreement, and in very few instances any thing that would deceive even an

unpractised eye, by the superficial resemblance of such an agreement.

If we cast a rapid view over the phenomena of this distribution, the subject must appear to present some of the most singular problems which can engage the attention of the inquirer into nature. First, We have a foundation of primitive rocks destitute of these organic remains; in the next succeeding series (that of transition,) corals, encrinites, and testacea, different however from those now known, appear at first sparingly. The fossil remains of the carboniferous limestone are nearly of the same nature with those in the transition rocks, but more abundant; the coal-measures (coal strata,) however, themselves, which repose on this limestone, present scarcely a single shell or coral; but, on the contrary, abound with vegetable remains, ferns, flags, reeds of unknown species, and large trunks of succulent plants, *strangers to the present globe.* Upon the coal rest beds again containing marine remains (the magnesian limestone), then a long interval (of new red sandstone) intervenes, destitute almost, if not entirely, of organic remains, preparing the way, as it were, for a new order of things. This order commences in the lias, and is continued in the oolites, green and iron sands, and chalk. All these beds contain corals, encrinites, echinites, testacea, crustacea, vertebral fishes, and marine oviparous quadrupeds, yet widely distinguished from the families contained in the lower beds of the transition and carboniferous class, and particularly distinguished among themselves, according to the bed which they occupy. Hitherto the remains are always petrified, i. e. impregnated in the mineral substance in which they are imbedded. But, lastly, in the strata which cover the chalk, we find the shells merely preserved, and in such a state that when the clay or sand in which they lie is washed off, they might appear to be recent, had they not lost their colour, and become more brittle. Here we find beds of marine shells alternating with others peculiar to fresh water, so that they seem to have been deposited by *reciprocating inundations of fresh and salt water.* In the highest of the regular strata, the crag, we at length can find an identity with the shells at present existing on the same coast; and, lastly, over all these strata indiscriminately there is spread a covering of gravel (seemingly formed by the action of a deluge, which has detached and rounded by attrition fragments of the rocks over which it swept,) containing the remains of numerous land quadrupeds, many of them of unknown genera or species (the mastodon, and the fossil species of elephant, or mammoth, bear, rhinoceros, and elk,) mingled with others (hyænas, &c.) equally strangers to the climates where they are now found, yet associated with many at present occupying the same countries.

Another class of substances imbedded in the secondary strata, and throwing light on the convulsions amidst which they have been formed, are the pebbles, or rolled fragments of rocks, older than themselves, which they are often found to contain.

The necessary inferences from this fact are, first, The rock whence the fragments were derived must have been consolidated, and, subsequently to that consolidation, have been exposed to the mechanical violence (probably the action of agitated waters) which tore from it these masses, and rounded them by attrition, before the rock in which these fragments are now imbedded was formed: and, secondly, Since loose gravel beds (and such must have been the original form of these, though now consolidated into conglomerate rocks) cannot be accumulated to any extent from the action of gravity on a highly inclined plane, we are sure, when we find such beds, as we often do in nearly vertical strata, that this cannot have been their original position, but is one into which they have been forced by convulsions which have dislocated them subsequently to their consolidation. These consolidated gravel beds are called conglomerates, breccias, or pudding stones; we find them among the transition rock, in the old red sandstone, in the mill-stone grits and coal-grits, in the lower members of the new red sandstone in the sand strata beneath the chalk, and in the gravel beds associated with the plastic clay, and interposed between the chalk and great London clay.

From the occurrence of the marine remains lately noticed, occupying, as they do, rocks spread over two-thirds of the surface of every part of our continents which have been explored, and rising to the highest situations, even to the loftiest summits of the Pyrenees, and still more elevated points on the Andes, it is an inevitable inference, that the greater part of those continents have not only been covered by, but have been formed of materials collected within the bosom of the ocean; that we inhabit countries which we may truly call *factas ex æquore terras.* The great and fundamental problem, therefore, of theoretical geology, is obviously to assign adequate causes for the change of level in this ocean, which has permitted these masses, which once formed the bottom of its channel, to rise in hills and mountains above its waves. The causes which it is possible to imagine are reducible to two general classes. First, The decrease of the absolute quantity of water. This must have resulted from causes entirely chemical, namely, the decomposition of some portion of the water, its constituents entering into new forms of combination; and its formation in the rocks formed beneath it. It is probable that these causes have operated to some degree, but it seems impossible to ascribe to them the very great difference of level for which we have to account.

The second class of possible causes is entirely mechanical; those, namely, which may have produced a change of relative level without any diminution of absolute quantity in the waters.

The causes of this kind which have been proposed are, first, The absorption of the waters into a supposed central cavity; but the now ascertained density of the earth (being greater than that which would result from an entirely solid sphere of equal magnitude of the most compact known rock) renders the existence of any such cavity very doubtful.

Secondly, A writer in the Journal of the Royal Institution, vol. ii. has proposed the very ingenious hypothesis, that a change of temperature of a few degrees will, from the unequal expansibility of the materials of land and water, sufficiently account for this change of level.

Thirdly, It has been ascribed to violent convulsions, which have either heaved up the present continents, or, which amounts to the same thing, (as the same relative change must have taken place in either view,) depressed the present channel of the ocean. If the violent elevation of the continent, or depression of the channel of the ocean, supposed in the last mentioned hypothesis, really took place, it must have left traces in the disturbed, contorted, and highly inclined position of the strata; and these disturbances must be the greatest where the change of level has been the greatest, *i. e.* in the neighbourhood of the loftiest mountains. Now this is actually the case.

In support of the hypothesis which ascribes an important part to volcanic agency in modifying the surface of our planet, the following, at least plausible, arguments might be adduced.

1. It must be kept in view, that the object is to assign an adequate cause for the undoubted fact of the emergence of the loftiest mountains of the present continent; and that when so mighty an effect is to be accounted for, the mind must be prepared to admit, without being startled, causes of a force and energy greatly exceeding those with which we are acquainted from actual observation.

2. The broken and disturbed state, and inclined position of the strata composing those continents, many of which must have been at the time of their original formation horizontal, indicate, as we have seen, that one at least of the causes operating to effect this great change of relative level between the land and waters, was the elevation of the former by mechanical force.

3. The only agent with which we are acquainted, whose operation bears any analogy to the effects above specified, is the volcanic energy which still occasionally forms new islands, and elevates new mountains.

4. Although these effects are now indeed partial and limited, yet there is certain proof that volcanic agency has formerly been much more active; the extinct volcanoes of the Rhine, Hungary, and Auvergne, as well as those which occupy so large a portion of Italy, where only one remains in activity, concur in proving, that at present we experience only the expiring efforts, as it were, of those gigantic powers which have once ravaged the face of nature.

5. If to this certain proof of the greater prevalence of volcanic convulsions in earlier, but still comparatively recent, periods of the history of our planet, we add the presumption that the trap rocks (so singularly intruded among the regular strata, and producing, where they traverse those strata, so precisely the effects of heat acting under compression, and so different in all their phenomena from formations decidedly aqueous,) were of volcanic origin, we shall find that scarcely a country exists, which has not been a prey to the ravages of this powerful principle. If, with many of the best geological observers, (Dr. M'Culloch, Von Buch, Necker, &c.) we incline to extend the same conclusions to granite rocks, a mass of volcanic power, clearly adequate to all the required effects, is provided.

6. The question will undoubtedly present itself, what is the source of volcanic action? And sufficient proof exists that this source is deeply seated beneath the lowest rocks with which our examination of the earth's surface makes us acquainted; for in Auvergne, the lavas have evidently been erupted from beneath the primitive rocks.

7. The very important recent discoveries with regard to the increased temperature noticed in descending deep mines, &c. by Messrs. Fox and Fourrier, will, if confirmed by further examination, prove, that some great source of heat exists beneath the earth's crust.

8. A degree of presumption may be thought to arise from these considerations, that the crust of the earth rests on a heated nucleus, the true source of volcanic energy. If this nucleus be in a fluid or viscous state, its undulations would readily account for the convulsions which have affected that crust, both in originally dislocating and elevating portions of its strata, and in the actual phenomena of earthquakes (of many of which phenomena no other hypothesis appears to offer a sufficient explanation,) while, at the same time, it would afford an adequate reason for the figure of the globe as a spheroid of rotation.

9. On this supposition, we should at once perceive a reason why the effects of the volcanic force may have been much more violent in earlier periods, while that mass of deposites which now covers the supposed volcanic nucleus, was but gradually forming over it, than at present; and we shall also find a reason for the higher temperature which many of the remains of both the animal and vegetable kingdoms, found in the strata of countries now too cold for the existence of their recent analogies, appear to indicate as having formerly prevailed.

10. It must be remembered, that one of the essential conditions of the theory above sketched is, the operation of volcanic agency beneath the pressure of an incumbent ocean; and that it does not, therefore, in any degree question the Neptunian origin of the majority of the rocks which have evidently been formed in the bosom of the ocean. With regard to the trap rocks alone, and perhaps the granitic, does it venture even to insinuate an opposite mode of formation?

Mr. Conybeare next shews, that the Wernerian generalization of the phenomena is too hasty. It supposes the basset edges of the strata to occupy levels successively lower and lower in proportion as they are of less ancient formation, and as they recede from the primitive chains, forming the edges of the basins in which they have been deposited. For if we compare the basset edges of the same strata on the opposite sides of the great European basin, (assuming the primitive ranges of our own island as one of its borders, and those of the Alpine chains as the other,) we shall find their level totally different.

The oolite, for instance, whose highest point with us is less than 1200 feet, attains a height of more than 4000 in the Jura chain, and in the mountains of the Tyrol has been observed by Mr. Buckland crowning some of the loftiest and most rugged summits of the Alps themselves. Again, if we compare the inclination of the strata at the edges of the basin, we shall find every thing but the supposed regular gradation, from a highly elevated to a horizontal position; on the contrary, we shall see the horizontal beds generally reposing at once upon the trun-

cated edges of those which lie at very considerable angles; and in place of the general conformity or parallelism which ought to prevail between the several formations, we shall observe, in many instances, appearances of the greatest irregularity in this respect; and these irregularities will be found to increase in approaching those chains which are the most elevated.

But if we suppose, that during the regular and gradual subsidence of the level of the ocean, in the Wernerian system, the continents were elevated by mechanical forces acting in a series of great convulsions, we shall perhaps obtain a nearer approximation to agreement with the actual phenomena, as deduced from observation. If these convulsions resulted from volcanic agency, we have already seen that there is every reason to believe this cause to have acted with most violence in the earliest periods; and this will sufficiently account for the greater derangement of the earlier rocks.

That the valleys have been, in many instances, entirely excavated by the agency of powerful aqueous currents, and in all, greatly modified by the same cause, seems as completely proved as the nature of the case can possibly admit. The same diluvial agency that has excavated the valleys, appears also to have swept off the superior strata from extensive tracts which they once covered. The proofs of this are to be found in insulated hills, or *outliers* of those strata, placed at considerable distances from their continuous range, with which they have every appearance of having been once connected; in the abrupt and truncated escarpments which form the usual termination of the strata, and in the very great quantity of their *debris*, scattered frequently over tracts far distant from those where they still exist *in situ*. This stripping off the *superstrata* is appropriately termed *denudation*.

The most important agency of this kind appears to have been exerted at an early period, and subsequently to the consolidation of all the strata, by an inundation which must have swept over them universally, and covered the whole surface with their *debris* indiscriminately thrown together, forming the last great geological change to which the surface of our planet appears to have been exposed.

To this general covering of water-worn *debris* derived from all the strata, the name of *diluvium* has been given, from the consideration of that great and universal catastrophe to which it seems most properly assignable. By this name it is intended to distinguish it from the partial *debris* occasioned by causes still in operation; such as the slight wear produced by the present rivers, the more violent action of torrents, &c. To the latter the name of *alluvium* has lately been appropriated. It does not seem possible to assign any single and uniform direction to the currents which have driven the diluvial *debris* before them; but they appear in every instance to have flowed (which indeed must of necessity be the case with the currents of subsiding waters,) as they were determined by the configuration of the adjoining country; from the mountains, that is, towards the lower hills and plains. As far as England is concerned, this principle will produce a general tendency to a direction from north-west towards south and east, greatly modified, however, by obvious local circumstances.

Another circumstance connected with the distribution of these travelled fragments is, that we often find them in masses of considerable size, accumulated in situations now separated by the intervention of deep valleys from the parent hills (if we may so speak,) whence we know them to have been torn. This appears to be a demonstrative proof that these intervening valleys must have been excavated subsequently to the transportation of these blocks; for though we can readily conceive how the agency of violent currents may have driven these blocks down an inclined plane, or if the *vis a tergo* were sufficient, along a level surface, or even up a very slight and gradual acclivity, it is impossible to ascribe to them the Sisyphean labour of rolling rocky masses, sometimes of many tons in weight, up the face of abrupt and high escarpments. The attention of geologists was first directed to this phenomenon by the discoveries of Saussure, who noticed one of its most striking cases—the occurrence of massive fragments torn from the primitive chains of the Alps, scattered at high levels on the escarpment of the opposite calcareous and secondary chains of the Jura, although between the two points, the deep valley containing the lake of Geneva is interposed. This phenomenon is one of very common occurrence. The Downs surrounding Bath (Hampton Down for example,) though abruptly scarped, and surrounded by valleys more than 600 feet deep, have yet on their very summits flints transported from the distant chalk hills. The simplest explanation of the fact will be, that these fragments were transported by the first action of the currents, before they had effected the excavation of the valleys, now cutting off all communication with the native rocks whence they were derived.

The organic remains of land animals dispersed through this diluvial gravel, must, with the greatest probability, be referred to the races extinguished by the great convulsion which formed that gravel; many of them are of species still inhabiting the countries where they are thus found; some of the species now inhabiting only other climates; and some few, of species and genera now entirely unknown.

To the same period we may ascribe the bones *of the same species with the above*, found in many caverns; but, in many of these instances, it is probable that some of the animals now found there, previously inhabited them as their dens. Professor Buckland appears to have proved satisfactorily, that this must have been the case in the remarkable instance of the cavern lately discovered near Kirby, Moorside, Yorkshire. Here the remains found in the greatest abundance are those of hyænas; with these are mingled fragments of various animals, from the mammoth to the water-rat. All the bones present evident traces of having been mangled and gnawed; and the whole are buried in a sediment of mud subsequently incrusted over by stalactical depositions. Professor Buckland's explanation is, that this cavern was occupied by the hyænas; who, according to the known habits of these animals, partially devoured even the bones of their prey, and dragged them for that purpose to their

dens; around their retreats, a similar *congeries* of mangled bones has been noticed by recent travellers. The proofs of these points, deduced from the circumstances of the cavern, the state of the bones, and the ascertained habits of the animals in question, appear to be decisive. The sediment in which the bones are imbedded, and the occurrence of the remains of the mammoths, and other species, only known (in these climates at least) in a fossil state, in the diluvial gravel, clearly refer their remains to the same era. Caverns containing bones of a similar class, the mammoth, the fossil species of a rhinoceros, &c. have been found near Swansea, at Hatton-hill, (on the Mendip chain in Somersetshire,) and near Plymouth.—*Rev. W. D. Conybeare, Introduction.*

The ancient history of the globe, which may be regarded as the *ultimate* object of geological researches, is undoubtedly one of the most curious subjects that can engage the attention of enlightened men. The lowest and most level parts of the earth, when penetrated to a very great depth, exhibit nothing but horizontal strata, composed of various substances, and containing almost all of them innumerable marine productions. Similar strata, with the same kind of productions, compose the hills even to a great height. Sometimes the shells are so numerous as to constitute the entire body of the stratum. They are almost every where in such a perfect state of preservation, that even the smallest of them retain their most delicate parts, their sharpest ridges, and tenderest processes. They are found in elevations far above the level of every part of the ocean, and in places to which the sea could not be conveyed by any presently existing cause. They are not merely enclosed in loose sand, but are often incrusted and penetrated on all sides by the hardest stones. Every part of the earth, every hemisphere, every continent, every island of any size, exhibits the same phenomenon. We are therefore forcibly led to believe, not only that the sea has at one period or another covered all our plains, but that it must have remained there for a long time, and in a state of tranquillity; which circumstance was necessary for the formation of deposites so extensive, so thick, in part so solid, and containing *exuviæ* so perfectly preserved. A nice and scrupulous comparison of the forms, contexture, and composition of these shells, and of those which still inhabit the sea, cannot detect the slightest difference between them. They have therefore once lived in the sea, and been deposited by it; the sea consequently must have rested in the places where the disposition has taken place. Hence it is evident, that the basin or reservoir containing the sea has undergone some change, either in extent, situation, or both.

The traces of revolutions, become still more apparent and decisive when we ascend a little higher, and approach nearer to the foot of the great chain of mountains. There are still found many beds of shells; some of these are even larger and more solid; the shells are quite as numerous, and as entirely preserved; but they are not of the same species with those which were found in the less elevated regions. The strata which contain them are not so generally horizontal; they have various degrees of inclination, and are sometimes situated vertically. While in the plains and low hills it was necessary to dig deep in order to detect the succession of the strata, here we perceive them by means of the valleys, which time or violence has produced, and which disclose their edges to the eye of the observer.

Thus the sea, previous to the formation of the horizontal strata, had formed others, which by some means have been broken, lifted up, and overturned in a thousand ways. But the sea has not always deposited stony substances of the same kind. It has observed a regular succession as to the nature of its deposites; the more ancient the strata are, so much the more uniform and extensive are they; and the more recent they are, the more limited are they, and the more variation is observed in them at small distances. Thus the great catastrophes which have produced revolutions in the basins of the sea, were preceded, accompanied, and followed by the changes in the nature of the fluid, and of the substances which it held in solution; and when the surface of the seas came to be divided by islands and projecting ridges, different changes took place in every separate basin.

These irruptions and retreats of the sea have neither been slow nor gradual: most of the catastrophes which have occasioned them have been sudden; and this is easily proved, especially with regard to the last of them, or the Mosaic deluge, the traces of which are very conspicuous. In the northern regions it has left the carcasses of some large quadrupeds, which the ice had arrested, and which are preserved even to the present day, with their skin, their hair, and their flesh. If they had not been frozen as soon as killed, they must have been quickly decomposed by putrefaction. But this perpetual frost could not have taken possession of the regions which these animals inhabited, except by the same cause which destroyed them: this cause must therefore have been as sudden as its effect. The two most remarkable phenomena of this kind, and which must for ever banish all idea of a slow and gradual revolution, are the rhinoceros, discovered in 1771 on the banks of the *Vilhoui*, and the elephant, recently found by Mr. Adams near the mouth of the *Sena*. This last retained its flesh and skin, on which was hair of two kinds; one short, fine, and crisped, resembling wool, and the other like bristles. The flesh was still in such high preservation, that it was eaten by dogs. Every part of the globe bears the impress of these great and terrible events so distinctly, that they must be visible to all who are qualified to read their history in the remains which they have left behind.—*See Cuvier's Theory of the Earth.*

GEOMETRY is that branch of mathematics which treats of the properties of extension and figure. The name is derived from the Greek term γεωμετρια, which properly signifies the science of land-measuring, as it was the necessity of measuring the land that first gave occasion to contemplate the principles and rules of this art, which has since been extended to numberless other speculations; insomuch that, together with arithmetic, geometry forms now the chief foundation of all the mathematics.

Herodotus and Proclus ascribe the inven

tion of geometry to the Egyptians, and assert that the annual inundations of the Nile gave occasion to it; for those waters bearing away the bounds and landmarks of estates and farms, covering the face of the ground uniformly with mud, the people, say they, were obliged every year to distinguish and lay out their lands by the consideration of their figure and quantity; and thus by experience and habit they formed a method or art, which was the origin of geometry.

Geometry is distinguished into theoretical or speculative, and practical.

Theoretical or speculative geometry treats of the various properties and relations in magnitudes, demonstrating the theorems, &c.

Practical geometry, is that which applies those speculations and theorems to particular uses in the solution of problems, and in the measurements in the ordinary concerns of life.

Speculative geometry again may be divided into elementary and sublime.

Elementary or common geometry, is that which is employed in the consideration of right lines and plane surfaces, with the solids generated from them.

And the higher or sublime geometry, is that which is employed in the consideration of curve lines, conic sections, and the bodies formed of them. This part has been chiefly cultivated by the moderns, by help of the improved state of algebra, and the modern analysis or fluxions.

We shall now proceed to give the principles of practical geometry, beginning with

Definitions.

1. A mathematical point has neither length, breadth, nor thickness. From this definition it may be easily understood that a mathematical point cannot be seen nor felt; it can only be imagined.

What is commonly called a point, as a small dot made with a pencil or pen, or the point of a needle, is not in reality a mathematical point; for however small such a dot may be, yet if it be examined with a magnifying glass, it will be found to be an irregular spot, of a very sensible length and breadth: and our not being able to measure its dimensions with the naked eye, arises only from its smallness.

2. A line is length without breadth or thickness. What was said above of a point, is also applicable to the definition of a line. A line therefore can only be imagined. The ends of a line are points.

3. Parallel lines are such as always keep at the same distance from each other, and which, if prolonged ever so far, would never meet. See Plate XIX, fig. 1.

4. A right line is what is commonly called a straight line, or one that tends every where the same way.

5. A curve is a line which continually changes its direction between its extreme points.

6. An angle is the inclination or opening of two lines meeting in a point, fig. 2.

7. The lines AB and BC, which form the angle, are called the legs or sides; and the point B, where they meet, is called the vertex of the angle, or the angular point. An angle is sometimes expressed by a letter placed at the vertex, as the angle B, fig. 2; but most commonly by three letters, observing to place in the middle the letter at the vertex, and the other two are those at the end of each leg, as the angle ABC.

8 When one line stands upon another, so as not to lean more to one side than to another, both the angles which it makes with the other are called right angles, as the angles ABC and ABD, fig. 3; and all right angles are equal to each other, being all equal to 90°; and the line AB is said to be perpendicular to CD.

Beginners are very apt to confound the terms perpendicular, and plumb or vertical line. A line is vertical when it is at right angles to the plane of the horizon, or level surface of the earth, or to the surface of water, which is always level. The sides of a house are vertical. But a line may be perpendicular to another, whether it stands upright, or inclines to the ground, or even if it lies flat upon it, provided only that it makes the two angles formed by meeting with the other line equal to each other; as for instance, if the angles ABC and ABD be equal, the line AB is perpendicular to CD whatever may be its position in other respects.

9. When one line BE (fig. 3.) stands upon another, CD, so as to incline, the angle EBC, which is greater than a right angle, is called an obtuse angle; and that which is less than a right angle is called an acute angle, as the angle EBD.

10. Two angles which have one leg in common, as the angles ABC and ABE, are called contiguous angles, or adjoining angles; those which are produced by the crossing of two lines, as the angles EBD and CBF, formed by CD and EF, crossing each other, are called opposite or vertical angles.

11. A figure is a bounded space, and is either a surface or a solid.

12 A superficies, or surface, has length and breadth only. The extremities of a superficies are lines.

13. A plane, or plane surface, is that which is every where perfectly flat and even, or which will touch every part of a straight line, in whatever direction it may be laid upon it. The top of a marble slasb, for instance, is an example of this, which a straight edge will touch in every point, so that you cannot see light any where between.

14. A curved surface is that which will not coincide with a straight line in any part. Curved surfaces may be either convex or concave.

15. A convex surface is when the surface rises up in the middle; as, for instance, a part of the outside of a globe,

16. A concave surface is when it sinks in the middle, or is hollow, and is the contrary to convex.

A surface may be bounded either by straight lines, curved lines, or both these.

17. Every surface bounded by straight lines only is called a polygon. If the sides are all equal, it is called a regular polygon. If they are unequal, it is called an irregular polygon. Every polygon, whether equal or unequal, has the same number of sides as angles, and they are denominated sometimes according to the number of sides, and sometimes from the number of angles they contain. Thus, a figure of three

sides is called a triangle, and a figure of four sides a quadrangle.

A pentagon is a polygon of five sides: a hexagon has six sides; a heptagon seven sides; an octagon eight sides; a nonagon nine sides; a decagon ten sides; an undecagon eleven sides: a duodecagon twelve sides.

When they have a greater number of sides, it is usual to call them polygons of 13 sides, of 14 sides, and so on.

Triangles are of different kinds, according to the lengths of their sides.

18. An equilateral triangle has all its sides equal, as ABC, fig. 4.

19. An isosceles triangle has two equal sides, as DEF, fig. 5.

20. A scalene triangle has all its sides unequal, as GHI, fig. 6.

Triangles are also denominated according to the angles they contain.

21. A right-angled triangle is one that has in it a right-angle, as ABC, fig. 7.

22. A triangle cannot have more than one right angle. The side opposite to the right angle B, as AC, is called the hypothenuse, and is always the longest side.

23. An obtuse-angled triangle has one obtuse angle, as fig. 8.

24. An acute-angled triangle has all its angles acute, as fig. 4.

25. An isosceles, or a scalene triangle, may be either right angled, obtuse, or acute.

26. Any side of a triangle is said to subtend the angle opposite to it: thus AB (fig. 7.) subtends the angle ACB.

27. If the side of a triangle be drawn out beyond the figure, as AD (fig. 8.) the angle A or CAB, is called an internal angle, and the angle CAD, or that without the figure, an external angle.

28. A quadrangle is also called a quadrilateral figure. They are of various denominations, as their sides are equal or unequal, or as all their angles are right-angles or not.

29. Every four-sided figure whose opposite sides are parallel, is called a parallelogram. Provided that the sides opposite to each other be parallel, it is immaterial whether the angles are right or not. Figs. 9, 10, 11, and 12, are all parallelograms.

30. When the angles of a parallelogram are all right angles, it is called a rectangular parallelogram, or a rectangle, as figs. 11 and 12.

31. A rectangle may have all its sides equal, or only the opposite sides equal. When all its sides are equal, it is called a square, as fig. 12.

32. When the opposite sides are parallel, and all the sides equal to each other, but the angles not right angles, the parallelogram is called a rhombus, as fig. 10.

33. A parallelogram having all its angles oblique, and only its opposite equal, is called a rhomboid, as fig. 9.

34. When a quadrilateral, or four-sided figure, has none of its sides parallel, it is called a trapezium, as fig. 13, consequently every quadrangle, or quadrilateral, which is not a parallelogram, is a trapezium,

35. A trapezoid has only one pair of its sides parallel, as fig. 14.

36. A diagonal is a right line drawn between any two angles that are opposite in a polygon, as IK, fig. 15. In parallelograms the diagonal is sometimes called the diameter, because it passes through the centre of the figure.

37. Complements of a parallelogram. If any point, as E (fig. 15.) be taken in the diagonal of a parallelogram, and through that point two lines are drawn parallel to the sides, as AB, CD, it will be divided into four parallelograms, D, D, L, F, G, G. The two divisions, L, F, through which the diameter does not pass, are called the complements.

38. Base of a figure, is the side on which it is supposed to stand erect, as AD and CD, fig. 16.

39. Altitude of a figure is its perpendicular height from the base to the highest part, as EF fig. 16.

40. Area of a plane figure, or other surface, means the quantity of space contained within its boundaries, expressed in square feet, yards, or any other superficial measure.

41. Similar figures are such as have the same angles, and whose sides are in the same proportion, as fig. 17.

42. Equal figures are such as have the same area or contents.

43. A circle is a plane figure, bounded by a curve line returning into itself, called its circumference, ABCD (fig. 18), every where equally distant from a point E within the circle which is called the centre.

44. The radius of a circle is a straight line drawn from the centre to the circumference, as EF, (fig. 18). The radius is the opening of the compass when a circle is described; and consequently all the radii of a circle must be equal to each other.

45. A diameter of a circle is a straight line drawn from one side of the circumference to the other through the centre, as CB (fig. 18.) Every diameter divides the circle into two equal parts.

46. A segment of a circle is a part of a circle cut off by a straight line drawn across it. This straight line is called the chord. A segment may be either equal to, greater, or less than, a semicircle, which is a segment formed by the diameter of the circle, as CEB, and is equal to half the circle.

47. A tangent is a strait line drawn so as just to touch a circle without cutting it, as GH (fig. 18.) The point A, where it touches the circle, is called the point of contact. And a tangent cannot touch a circle in more points than one.

48. A sector of a circle is a space comprehended between two radii and an arc, as IK, (fig. 19.)

49. The circumference of every circle, whether great or small, is supposed to be divided into 360 equal parts, called degrees· and every degree into 60 parts, called minutes, and every minute into 60 seconds. To measure the inclination of lines to each other, or angles, a circle is described round the angular point as a centre, as IK, (fig. 19;) and according to the number of degrees, minutes, and seconds, cut off by the sides of the angle, so many degrees, minutes, and seconds, it is said to contain. Degrees are marked by $^\circ$, minutes by $'$, and seconds by $''$; thus an angle of 48 degrees, 15 minutes, and 7 seconds, is written in this manner, $48^\circ\ 15'\ 7''$

50. A solid is any body that has length,

breadth, and thickness: a book, for instance, is solid, so is a sheet of paper; for though its thickness is very small, yet it has some thickness. The boundaries of a solid are surfaces.

51. Similar solids are such as are bounded by an equal number of similar planes.

52. A prism is a solid, of which the sides are parallelograms, and the two ends or bases are similar polygons, parallel to each other. Prisms are denominated according to the number of angles, in the base, triangular prisms, quadrangular, heptangular, and so on, as figs. 20, 21, 22, 23. If the sides are perpendicular to the plane of the base, it is called an upright prism; if they are inclined, it is called an oblique prism.

53. When the base of a prism is a parallelogram, it is called a parallelopipedon, as figs. 22 and 23. Hence a parallelopipedon is a solid terminated by six parallelograms.

54. When all the sides of a parallelopipedon are squares the solid is called a cube, as fig. 23.

55. A rhomboid is an oblique prism, whose bases are parallelograms (fig. 24.)

56. A pyramid (figs. 25 and 26) is a solid bounded by, or contained within, a number of planes, whose base may be any polygon, and whose faces are terminated in one point, B, commonly called the vertex of the pyramid.

57. When the figure of the base is a triangle, it is called a triangular pyramid; when the figure of the base is a quadrilateral, it is called a quadrilateral pyramid, &c.

58. A pyramid is either regular or irregular, according as the base is regular or irregular.

59. A pyramid is also right or upright, or it is oblique. It is right, when a line drawn from the vertex to the centre of the base, is perpendicular to it, as fig. 25: and oblique, when this line inclines, as fig. 26.

60. A cylinder is a solid (figs. 27. and 28,) generated or formed by the rotation of a rectangle about one of its sides, supposed to be at rest: this quiescent side is called the axis of the cylinder. Or it may be conceived to be generated by the motion of a circle, in a direction perpendicular to its surface, and always parallel to itself.

61. A cylinder is either right or oblique, as the axis is perpendicular to the base or inclined.

62. Every section of a right cylinder taken at right angles to its axis, is a circle; and every section taken across the cylinder, but oblique to the axis, is an ellipsis

63. A circle being a polygon of an infinite number of sides, it follows, that the cylinder may be conceived as a prism, having such a polygon for bases.

64. A cone is a solid, (figs. 29 and 30,) having a circle for its base, and its sides a convex surface, terminating in a point A, called the vertex, or apex of the cone. It may be conceived to be generated by the revolution of a right-angled triangle about its perpendicular.

65. A line drawn from the vertex to the centre of the base is the axis of the cone.

66. When this line is perpendicular to the base the cone is called an upright, or right cone; but when it is inclined it is called an oblique cone.

67. If it be cut through the axis from the vertex to the base, the section will be a triangle.

68. If a right cone be cut by a plane at right angles to the axis, the section will be a circle.

69. If it be cut oblique to the axis, and quite across from one side to the other, the section will be an ellipsis, as fig. 31. A section of a cylinder made in the same manner is also an ellipsis; and that is easily conceived: but it does not appear so readily that the oblique section of a cone is an ellipsis: it is frequently imagined that it will be wider at one end than the other, or what is called an oval, which is the shape of an egg. But that this is a mistake, any one may convince himself by making a cone, and cutting it across obliquely; it will be then seen that the section, in whatever direction it is taken, is a regular ellipsis; and this is the case, whether the one be right or oblique, except only in one case in the oblique cone; which is when the section is taken in a particular direction, which is called sub-contrary to its base.

70. When the section is made parallel to one of the sides of the cone, as fig. 32, the curve ABC, which bounds the section, is called a parabola.

71. When the section is taken parallel to the axis as fig. 33, the curve is called an hyperbola.

These curves, which are formed by cutting a cone in different directions, have various properties, which are of great importance in astronomy, gunnery, perspective and many other sciences.

72. A sphere is a solid, terminated by a convex surface, every point of which is at an equal distance from a point within, called the centre, fig. 34.

73. It may be conceived to be formed by making a semicircle revolve round its diameter. The diameter of the semicircle round which it revolves, is called the axis of the sphere.

74. The ends of the axis are called poles.

75. Any line passing through the centre of the sphere, and terminated by the circumference, is a diameter of the sphere.

76. Every section of a sphere is a circle; every section taken through the centre of the sphere is called a great circle, as AB, fig. 34; every other is a lesser circle, as CD.

77. Any portion of a sphere cut off by a plane is called a segment; and when the plane passes through the centre, it divides the sphere into two equal parts, each of which is called a hemisphere.

78. A spheroid is a solid (fig. 35,) generated by the rotation of a semi-ellipsis about the transverse or conjugate axis; and the centre of the ellipsis is the centre of the spheroid.

79. The line about which the ellipsis revolves is called the axis. If the spheriod be generated about the conjugate axis of the semi-ellipsis, it is called a prolate spheroid.

80. If the spheroid be generated by the semi-ellipsis by revolving about the transverse axis, it is called an oblong spheroid.

81. Every section of a spheriod is an ellipsis, except when it is perpendicular to that axis about which it is generated; in which case it is a circle.

82. All sections of a spheroid parallel to each other, are similar figures.

A frustum of a solid, means a piece cut off from the solid by a plane passed through it, usually parallel to the base of the solid, as the frustum of a cone, a pyramid, &c.

There are a lower and an upper frustum, according as the piece spoken of does or does not contain the base of the solid.

83. Ratio is the proportion which one magnitude bears to another of the same kind, with respect to quantity, and is usually marked thus, A : B.

Of these the first is called the antecedent, and the second the consequent.

84. The measure or quantity of a ratio is conceived by considering what part of the consequent is the antecedent; consequently it is obtained by dividing the consequent by the antecedent.

85. Three magnitudes or quantities, A, B, C, are said to be proportional, when the ratio of the first to the second is the same as that of the second to the third. Thus 2, 4, 8, are proportional; because 4 is contained in 8 as many times as 2 is in 4.

86. Four quantities, A, B, C, D, are said to be proportional when the ratio of the first A to the second B is the same as the ratio of the third C to the fourth D. It is usually written A : B :: C : D, or, if expressed in numbers, 2 : 4 :: 8 : 16.

87. Of three proportional quantities, the middle one is said to be a mean proportional between the other two: and the last a third proportional to the first and second.

88. Of four proportional quantities, the last is said to be a fourth proportional to the other three, taken in order.

89. Ratio of equality is that which equal numbers bear to each other.

90. Inverse ratio is when the antecedent made the consequent, and the consequent the antecedent. Thus, if 1 : 2 :: 3 : 6; then inversely, 2 : 1 :: 6 : 3.

91. Alternate proportion is when antecedent compared with antecedent, and consequent with consequent. Thus, if 2 : 1 :: 6 : 3; then by alternation 2 : 6 :: 1 : 3.

92. Proportion by composition is when the antecedent and consequent, taken as one quantity, are compared either with the consequent or with the antecedent. Thus, if 2 : 1 :: 6 : 3; then by composition 2 + 1 : 1 :: 6 + 3 : 3; and 2 + 1 : 2 :: 6 + 3 : 6.

93. Divided proportion is when the difference of the antecedent and consequent is compared either with the consequent or with the antecedent. Thus, if 3 . 1 :: 12 : 4; then by division, 3 − 1 : 1 :: 12 − 4 : 4, and 3 − 1 : 3 :: 12 −4 : 12.

94. Continued proportion is when the first is to the second; as the second to the third; as the third to the fourth; as the fourth to the fifth; and

95. Compound ratio is formed by the multiplication of several antecedents and the several consequents of ratios together, in the following manner:

If A be to B as 3 to 5, B to C as 5 to 8, and C to D as 8 to 6; then A will be to D, as $\frac{3 \times 5 \times 8}{5 \times 8 \times 6} = \frac{120}{240}$ that is A . D :: 1 : 2.

96. *Bisect* means to divide any thing into two equal parts.

97. *Trisect* is to divide any thing into three equal parts.

98. *Inscribe*, to draw one figure within another, so that all angles, of the inner figure touch either the angles, sides, or plane, of the external figure.

99. *Circumscribe*, to draw a figure round another, so that either the angles, sides, or planes of the cirsumscribed figure, touch all the angles of the figure within it.

100. Rectangle under any two lines, means a rectangle which has two of its sides equal to one of the lines, and two of them equal to the other. Also the rectangle under AB, CD, means AB × CD.

101. Scales of equal parts. A scale of equal parts is only a straight line, divided into any number of equal parts at pleasure. Each part may represent any measure required, as an inch, a foot, a yard, &c. One of these is generally subdivided into parts of the next denomination, or into tenths or hundredths. Scales may be constructed in a variety of ways. The most usual manner is to make an inch, or some aliquot part of an inch to represent a foot; and then they are called inch-scales, three-quarter-inch scales, half-inch scales, quarter-inch scales, &c. They are usually drawn upon ivory or boxwood.

102. An axiom is a manifest truth, not requiring any demonstration.

103. Postulates are things required to be granted true, before we proceed to demonstrate a proposition.

104. A proposition is when something is either proposed to be done, or to be demonstrated, and is either a problem or a theorem.

105. A problem is when something is proposed to be done, as some figure to be drawn.

106. A theorem is when something is proposed to be demonstrated or proved.

107. A lemma is when a premise is demonstrated in order to render the thing in hand the more easy.

108. A corollary is an inference drawn from the demonstration of some proposition.

109. A scholium is when some remark or observation is made upon something mentioned before.

Geometrical Problems.

Prob. 1. To divide a given line AB; Plate XX. into two equal parts.

From the points A and B as centres, and with any opening of the compasses greater than half AB, describe arches, cutting each other in c and d. Draw the line c d; and the point E, where it cuts AB, will be the middle required.

Prob. 2. To raise a perpendicular to a given line AB, from a point given at C.

Case 1. When the given point is near the middle of the line on each side of the point C. Take any two equal distances, C d and C e; from d, and e, with any radius or opening of the compasses greater than C d, or C e, describe two arcs cutting each other in f. Lastly, through the points f, C, draw the line f C, and it will be the perpendicular required.

Case 2. When the point is at, or near, the end of the line. Take any point d, above the line, and with the radius or distance d C,

describe the arc e C f, cutting AB in e and C. Through the centre d, and the point e, draw the line e d f, cutting the arc e C f in f. Through the points f, C, draw the line f C, and it will be the perpendicular required.

Prob. 3. From a given point f, to let fall a perpendicular upon a given line AB.

From the point f, with any radius, describe the arc d e, cutting AB in e and d. From the points e d, with the same or any other radius, describe two arcs, cutting each other in g, Through the points f and g, draw the line f g, and f C will be the perpendicular required.

Prob. 4. To make an angle equal to another angle which is given, as to B b.

From the point B, with any radius, describe the arc a b, cutting the legs B a, B b, in the points a and b. Draw the line D e, and from the point D, with the same radius as before, describe the arc e f, cutting D e in e. Take the distance b a, and apply it to the arc e f, from e to f. Lastly, through the points D, f, draw the line D f, and the angle e D f will be equal to the angle b B a, as was required.

Prob. 5. To divide a given angle, ABC, into two equal angles.

From the point B. with any radius describe the arc AC. From A and C with the same, or any other radius describe arcs cutting each other in d. Draw the line B d, and it will bisect the angle ABC, as was required.

Prob. 6. To lay down an angle of any number of degrees.

There are various methods of doing this One is by the use of an instrument called a protractor, which is a semicircle of brass, having its circumference divided into degrees. Let AB be a given line, and let it be required to draw from the angular point A, a line making with AB any number of degrees, suppose 50. Lay the straight side of the protractor along the line AB, and count 50° from the end B of the semicircle ; at C, which is 50° from B. mark ; then, removing the protractor, draw the line AC, which makes with AB the angle required. Or it may be done by a line. usually drawn upon scales, called a line of chords.

Prob. 7. Through a given point C, to draw a line parallel to a given line AB.

Case 1. Take any point d, in AB: upon d and C, with the distance C d, describe two arcs, e C, and d f, cutting the line AB in e and d. Make d f equal to e C; through C and f draw C f and it will be the line required.

Case 2. When the parallel is to be at a given distance from AB. From any two points, c and d, in the line AB, with a radius equal to the given distance, describe the arcs e and f; draw the line CB to touch those arcs without cutting them, and it will be parallel to AB, as was required.

Prob. 8. To divide a given line AB, into any proposed number of equal parts.

From A, one end of the line, draw A c, making any angle with AB; and from B, the other end, draw B d, making the angle AB d equal to BA c. In each of these lines, A c, B d, beginning at A and B, set off as many equal parts of any length as AB is to be divided into. Join the points C 5, 46, 57, and AB will be divided as required.

Prob. 9. To find the centre of a given circle, or of any one already described. Draw any chord, AB, and bisect it with the perpendicular CD. Bisect CD with the diameter EF. and the intersection O will be the centre required.

Prob. 10. To draw a tangent to a given circle that shall pass through a given point A.

From the centre O, draw the radius OA. Through the point A, draw DE perpendicular to OA, and it will be the tangent required.

Prob. 11. To draw a tangent to a circle, or any segment of a circle ABC, through a given point B, without making use of the centre of the circle.

Take any two equal divisions upon the circle from the given point B, towards d and e, and draw the chord e B. Upon B, as a centre, with the distance B d, describe the arc f d g, cutting the chord e B in f. Make d g equal to d f; through g draw g B, and it will be the tangent required.

Prob. 12. Given three points, A, B, C, not in a straight line, to describe a circle that shall pass through them.

Bisect the lines AB, BC, by the perpendiculars a d, b d, meeting at d. Upon d, with the distance d A, d B, describe ABC, and it will be the required circle.

Prob. 13. To describe the segment of a circle to any length AB, and height CD.

Bisect AB by the perpendicular D g, cutting AB in c. From c make c D on the perpendicular equal to CD. Draw AD, and bisect it by a perpendicular e f, cutting D g in g. Upon g the centre, describe ADB, and it will be the required segment.

Prob. 14. In any given triangle to inscribe a circle.

Bisect any two angles, A and C, with the lines AD and DC. From D the point of intersection, let fall the perpendicular DE ; it will be the radius of the circle required.

Prob. 15. In a given square, to describe a regular octagon.

Draw the diagonals AC and BD, intersecting at e. Upon the points A, B, C, D, as centres, with a radius e C, describe the arcs k e n, m e g. f e i, &c. Join f n, m h, k i, l g, and it will be the required octagon.

Prob. 16. In a given circle. to describe any regular polygon.

Divide the circumference into as many parts as there are sides in the polygon to be drawn, and join the points of division.

Prob. 17. Upon a given line AB, to construct an equilateral triangle.

Upon the points A, and B, with a radius equal to AB, describe arches cutting each other at C. Draw AC and BC, and ABC will be the triangle required.

Prob. 18 To make a trapezium equal and similar to a given trapezium ABCD.

Divide the given trapezium ABCD into two triangles by the diagonal DB. Make EF equal to AB ; upon EF construct the triangle EFH, whose sides shall be respectively equal to those of the triangle ABD by the last problem. Upon HF, which is equal to DB, construct the triangle HFG, whose sides are respectively equal to DBC ; then EFGH will be the trapezium required.

By the help of this problem any plan may be copied ; as every figure however irregular, may be divided into triangles. Upon this the practice of land-surveying and making plans of estates, is founded.

Prob. 19. To make a square equal to two given squares. Make the sides DE and DF of the two given squares A and B, form the sides of a right-angled triangle FDE; draw the hypothenuse FE; on it describe the square EFGH, and it will be the square required.

Prob. 20. Between two given lines, AB and CD, to find a mean proportional.

Draw the right line EG, in which make EF equal to AB, and FG equal to CD. Bisect EG in H, and with HE or HG, as radius, describe the semicircle EIG. From F draw FI perpendicular to EG, cutting the circle in I; and IF will be the mean proportional required.

With respect to the application of geometry to its pristine intent, namely, the measurement of land, we must refer our readers to SURVEYING; under which head it will be found practically exemplified.

GEORGIC, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry.

GERANIUM, *crane's-bill*, a genus of the decandria order, in the monadelphia class of plants, and in the natural method ranking under the 14th order, gruinales. Its characters are these: the flower has a permanent empalement, composed of five small oval leaves, and five oval or heart-shaped petals, spreading open, which are in some species equal, and in others the upper two are much larger than the three lower. It has ten stamina, alternately longer than each other, but shorter than the petals, and terminated by oblong summits. In the bottom of the flower is situated a five-cornered germen, which is permanent. The flower is succeeded by five seeds, each being wrapped up in the husk of the beak, where they are twisted together at the point, so as to form the resemblance of a stork's beak. There are 32 species.

GERMINATION. When a seed is placed in a situation favourable to vegetation, it very soon changes its appearance; the radicle is converted into a root, and sinks into the earth; the plumula rises above the earth, and becomes the trunk or stem. When these changes take place, the seed is said to germinate; the process itself has been called germination, which does not depend upon the seed alone; something external must affect it. Seeds do not germinate equally and indifferently in all places and seasons, they require moisture and a certain degree of heat, and every species of plant seems to have a degree of heat peculiar to itself, at which its seeds begin to germinate; air also is necessary to the germination of seeds; it is for want of air that seeds which are burried at a great depth either thrive but indifferently, or do not rise at all. They frequently preserve, however, their germinating virtues for many years within the bowels of the earth; and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants which had not been seen there in the memory of man. Light is supposed to be injurious to the process, which affords a reason for covering seeds with the soil in which they are to grow, and for carrying on the business of malting in darkened apartments; malting being nothing more than germination. converted with a particular view

GEROPOGON, a genus of the syngenesia polygamia æqualis class and order. There are three species, all plants of Italy, having the same habit with the tragopogons.

GESNERIA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There are 12 species, herbs and shrubs of the West Indies.

GETHYLLIS, a genus of the monogynia order, in the dodecandria class of plants, and in the natural method ranking under the 9th order, spathaceæ. There are four species, herbs of the Cape.

GIANT'S *causeway*, a vast collection of a black kind of marle, called basaltes, in the county of Antrim, in Ireland. See BASALTES.

GIBBOUS, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned; and the light one convex or gibbous.

GIFT, in law, a transferring the property in a thing from one to another without a valuable consideration; for to transfer any thing upon a valuable consideration, is a contract or sale. He who gives any thing is called the donor, and he to whom is given is called the donee. By the common law all chattels, real or personal, may be granted or given without deed, except in some special cases, and a free gift is good without a consideration, if not to defraud creditors. But no leases, estates, or interests, either of freehold or term of years, on any uncertain interest, not being copyhold or customary interest of, in, to, or out of any messuages, manors, lands, tenements, or hereditaments, shall at any time be assigned, granted, or surrendered, unless it be by deed or note in writing, signed by the party so assigning, granting, or surrendering the same, or their agents thereunto lawfully authorized by writing; or by act and operation of law.

GILDING. The art of covering the surfaces of bodies with gold. The gold prepared for painting is called shell-gold or gold-powder, and may be obtained by amalgamating one part of gold with eight of quicksilver, and afterwards evaporating the latter, which leaves the gold in the form of powder; or the metal may be reduced to powder by mechanical trituration. For this purpose, gold leaf must be ground with honey or strong gum-water for a long time; and when the powder is sufficiently fine, the honey or gum may be washed off with water

For gold gilding by friction, a fine linen rag is steeped in a saturated solution of gold, till it has entirely imbibed the liquor; this rag is then dried over a fire, and afterward burned to tinder. When any thing is to be gilded, it must be previously well burnished; a piece of cork is then to be dipped, first into a solution of salt in water, and afterward into the black powder; and the piece, after it is burnished, rubbed with it.

For water gilding, the solution of gold may be evaporated till it is of an oily consistence, suffered to crystallize, and the crystals dissolved in water be employed instead of the acid solution. If this be copiously diluted with alcohol, a piece of clean iron will be gilded by being steeped therein Or add to the solution

about three times its quantity of sulphuric ether, which will soon take up the nitro-muriate of gold, leaving the acid colourless at the bottom of the vessel, which must then be drawn off. Steel dipped into the ethereal solution for a moment, and instantly washed in clean water, will be completely and beautifully covered with gold. The surface of the steel must be well polished, and wiped very clean.

For the method called Grecian gilding, equal parts of sal ammoniac and corrosive sublimate are dissolved in nitric acid, and a solution of gold is made in this menstruum: upon this the solution is somewhat concentrated, and applied to the surface of silver, which becomes quite black; but, on being exposed to a red heat, it assumes the appearance of gilding.

The method of gilding silver, brass, or copper, by an amalgam, is as follows: Eight parts of mercury, and one of gold, are incorporated together by heating them in a crucible. As soon as the gold is perfectly dissolved, the mixture is poured into cold water, and is then ready for use.

Before the amalgam can be laid upon the surface of the metal, this last is brushed over with dilute aqua fortis, in which it is of advantage that some mercury may have been dissolved. Some artists then wash the metal in fair water, and scour it a little with fine sand, previous to the application of the gold; but others apply it to the metal while still wet with the aquafortis. But in either case the amalgam must be laid on as uniformly as possible, and spread very evenly with a brass-wire brush, wetted occasionally with fair water. The piece is then laid upon a grate, over a charcoal fire, or in a small oven or furnace adapted to this purpose. The heat drives off the mercury, and leaves the gold behind. Its defects are then seen, and may be remedied by successive applications of more amalgam, and additional application of heat. The expert artists, however, make these additional applications while the piece remains in the furnace, though the practice is said to be highly noxious on account of the mercurial fumes. After this it is rubbed with gilders' wax, which may consist of four ounces of bees' wax, one ounce of verdigris, and one ounce of sulphate of copper; then expose it to a red heat, which burns off the wax; and, lastly, the work is cleared with the scratch brush, and burnished, if necessary, with a steel tool. The use of the wax seems to consist merely in covering defects, by the diffusion of a quantity of red oxide of copper, which is left behind after the burning.

The gilding of iron by mere heat is performed by cleaning and polishing its surface, and then heating it till it has acquired a blue colour. When this has been done, the first layer of gold leaf is put on, slightly burnished down, and exposed to a gentle fire. It is usual to give three such layers, or four at the most, each consisting of a single leaf for common works, or two for extraordinary ones. The heating is repeated at each layer, and last of all the work is burnished.
